CASE 1.—Patient a little Scotch woman who has suffered from the disease for over twenty years; she was confined to bed when I saw her, where she had been for some months, nearly all the joints of the body being involved. The patient suffered greatly and had to be given morphine repeatedly to enable her to get rest. For some years back had been unable to comb her hair or button her skirt; was much emaciated. The nodes were greatly enlarged and I obtained lymph from both the vertical and horizontal nodes in the groin. I inoculated fully six blood serum tubes and at the end of the third day a sparse growth developed on four of the tubes and diplococci in pure culture were recovered. A vaccine was made and I inoculated the patient with 200,000,000 dead organisms; this was increased gradually to one billion which was given every four or five days. The reaction was marked, slight temperature, increased pain in joints and delirium. After the third day, however, the patient felt better and improvement has been steady until at the present time she does not suffer any ache or pain, walks well, does her own housework, sleeps soundly and is heavier than she has ever been. The nodes gradually reduced in size; in about two or three months' time I inserted a needle into an inguinal node and obtained a mixed culture of diplococci and a thin short bacillus; after six months it was with difficulty that I could palpate the gland. However, I obtained lymph and inoculated several tubes and got no growth at all.

CASE 2.—Mr. C., a little over 50 years of age. The nodes were much enlarged but here I obtained no growth. When he came under my care his condition was far from being one of comfort; nearly all the joints were involved, he could not feed himself, or shave, or light a match. He came to see me on crutches but with considerable difficulty owing to the swollen and painful condition of the joints of his arms and hands. He was confined to bed for weeks, suffered great pain and could not sleep. I inoculated him with the diplococcus organism obtained from the first case and in a short time he showed much improvement. At present, after three or four months' treatment, his condition is very satisfactory. He can work his farm and claims that he can run, and his grip is good, while he now shaves himself with ease and sleeps soundly.

CASE 3.—This case is of considerable interest. About one year ago Mrs. J., a stout, healthy-looking woman, came under my care suffering from acute inflammatory rheumatism. I treated her with sodium salicylate 20 grains, sodium bicarbonate 40 grains, every two hours. In spite of this, however, she developed endocarditis. The condition continued for about five weeks when she left for home. Later the rheumatism recurred and she continued with the treatment. The metacarpo-phalangeal joints, however, remained swollen and painful and the phalangeal joints were in the same condition and no treatment seemed to help her. I decided that I was dealing with a case of rheumatoid arthritis which had become engrafted upon the rheumatic joints. I inoculated her with the diplococcus organism, giving 500,000,000 as a primary dose and in three days the swelling had nearly entirely disappeared. She was given a second dose of 750,000,000, and she left for home feeling quite well. The result was rapid in this case as I was dealing with the early stage of the disease—we cannot expect to get this result in conditions which have lasted for 15 or 20 years as in the foregoing two cases.

CASE 4.—Mr. C., æt. about 38. Here most of the joints were involved, he suffered a great deal and could not put his coat on by himself or shave and

was able to walk only with difficulty. He had lost his position on account of this disability. He was given two inoculations of the short bacillus and four or five of the diplococcus. He is now at work again, feels well, can put on his coat and shaves with ease. I gave him 500,000,000 as a primary dose and increased to 1,500,000,000.

CASE 5.—This case is under my care at the present time, having suffered from rheumatoid arthritis for over ten years. Most of her joints are involved and a great deal of her time has been spent in the house; she suffers greatly. I gave her two or three doses of the short bacillus without any benefit. She was then given four or five doses of the diplococcus with the result that she is now showing marked improvement, feels better than she has done for six years, can walk down stairs without any help and I expect to have a complete recovery in this case.

CASE 6.—This case is one of considerable chronicity lasting over 20 years, and the patient has suffered greatly during that time, with occasional remissions. She has tried every form of treatment: hot baths at the south, Schaeffer's rheumatic vaccine, and a vaccine made of the colon bacillus, but the disease has gradually progressed; the hands and knee-joints are the parts which are most affected. The X-ray picture shows a marked and chronic condition of this disease. I gave this patient the diplococcus and later tried the short bacillus but improvement has been slow and at the present time I am giving her the diplococcus and bacillus vaccines combined. I cannot claim much for this case, but comparing her condition with this time last year she does not now have the intense suffering experienced on wet and damp days which now pass without influencing her condition, and I may add that there has been a great improvement in her general state. I obtained from this patient the short bacillus from an enlarged node. We are, however, encouraged to continue the treatment in this case.

CASE 7.—Mrs. P., who has suffered from this disease for over ten years; both knees, shoulders and elbows are involved. She is over 55 years of age, and for years has walked with difficulty and has suffered greatly. After receiving 15 to 20 inoculations she can now walk with ease, without pain, and states that she feels like a new woman. I expect to obtain a complete cure also in this case. I may state that I gave her inoculations of the short bacillus which produced no improvement, but the improvement after using the diplococcus was marked, rapid and permanent.

CASE 8.—This was one of the severe chronic cases, nearly every joint being involved. There was marked deformity of the hands and feet, the elbows, ankles, knees, hips, and spine were all affected, as also were the thyroid cartilage and laryngeal rings. The patient had not raised her head from the pillow for seven or eight years and rotation of it was impossible. There was a constant accumulation of mucus in the bronchial tubes. She has had five or six injections of the short bacillus and the same of the diplococcus organisms and I am pleased to say she can now sit up and has even been out of bed. Most of the joints show a marked improvement and she can rotate her head with ease.

CASE 9.—Mrs. D., an old lady of over 70 years of age. She has had inoculations of the diplococcus organism, is now out of bed and shows marked general improvement; she can move her hands and arms much better and without much pain.

CASES 10, 11, 12.—In these I have found the diplococcus and will begin the treatment in a short time. Two of the cases are in Columbia, South

Carolina, one giving the diplococcus, the other the short bacillus. I have to thank Dr. Pope and Dr. J. Watson for referring them to me. I have other cases under observation which I will treat in the near future.

As I have found this identical diplococcus in the urine of patients suffering from rheumatoid arthritis I had a vaccine made from it but cannot claim any results from its use. I believe, however, that at one time or another the urine from rheumatoid arthritis patients will show this diplococcus, but I think that by the time that Nature excretes this organism from the kidneys it has become attenuated and will not produce toxins to any extent. In fact, it has become practically non-pathogenic.

Most of my good results have been obtained by giving the diplococcus organism. The question arises, why can I not obtain the same results by using the short spore-bearing bacillus? This bacillus produces spores which are most resistant to heat and also to a small percentage of phenol, and I am afraid that the amount of phenol used destroys the toxins and thus we cannot look for any results from the use of this bacillus until we can devise some other and safer method of destroying the bacilli without rendering the toxins inert.

CONCLUSIONS.

1. In ten out of the twelve cases of rheumatoid arthritis I have recovered organisms from the enlarged nodes, one being a diplococcus and the other a thin short bacillus, either in pure culture or mixed. A vaccine made from the diplococcus produces a cure or a marked improvement in the local and general lesions and symptoms in patients who suffer from rheumatoid arthritis. A vaccine made from the short bacillus improves the general condition and lessens the pain.

2. In the early stages of the disease—that is, up to the third or fourth year, before the grave articular changes have taken place in the joints, we can hope for return of the joint function, absence of pain and disappearance of swelling around the joints. In the chronic cases of 15 or 20 years' standing, we get a marked improvement, the pain disappears, the joint function improves and the patient increases in weight and feels well. (Case 1, Mrs. P.) and these encouraging results have been obtained by the use of the diplococcus vaccine.

3. The diplococcus has been found in the urine as well as in the nodes.

4. Cultures obtained from the nodes after four or five months' treatment in severe cases and in much less time in early cases were negative notwithstanding the fact that the diplococcus has been found in the nodes before treatment began.

5. In early cases we can look for results after three to four inoculations: in the chronic cases one may not detect much improvement before two or three months' treatment.

6. In chronic or advanced cases we cannot expect to restore articular cartilages or to produce new joints. However, we expect to get an absence of pain, increased motion and lessening of swelling.

7. The initial dose for an adult should be 150,000,000 to 200,000,000, increased rapidly to 300,000,000, 400,000,000, 500,000,000, 750,000,000, 100,000,000, to 1,500,000,000. However, the dose will depend upon the reaction and general condition of the patient and should be administered every three to four days. It may have to be continued for months. I may state here that I do not look for a reaction in every case, and a marked reaction, that is, temperature, pain, is not necessary to produce results.

I think that the results obtained by the use of this diplococcus in rheumatoid arthritis patients

warrant me in believing that it is the principal organism which causes this disease, and considering that the disease is progressive and that no known medicinal treatment will give the same results, I think that the value of the above treatment is evident.

Since writing the above paper, Case 6 shows marked improvement, the progress of the disease has been entirely arrested. This patient is receiving doses of from eleven to fifteen billions of the diplococci, with marked reaction.

I have at present under my care a delicate young girl, sixteen years of age, who is almost cured. She has been receiving five to six billions diplococci per dose.

After giving patient three or four of these heroic doses it is well to stop treatment for a week or ten days.

WOUND DRESSINGS.*

By DOUGLAS H. STEWART, M.D., F.A.C.S.,
New York.

In order to study wound healing, the writer of this paper took charge of a surgical clinic which furnished a minimum of twenty septic patients per day with as many additional ones as he could attend in the time at his disposal. Unhealed laparotomies and other operative wounds, gangrene, burns, lacerations, contusions, punctures, incisions, railroad, machinery and traffic accidents and their consequences would make up most of the list of cases. A battlefield, after a cavalry charge, would give a fair picture of the state of things which was encountered. For there the least injuries would be those inflicted by the sabre and rifle, but human flesh would be smashed out of semblance by the flying and contaminated hoofs of the troop horses, or would be crushed and poisoned by the mud-befouled rim of the rolling wheel of the light artillery and of the ammunition wagon.

Many septic cases came together, because experience with non-adherent bandages resulted in one appreciative patient bringing some injured friend with him on his return to the clinic. To quote a nurse, "The non-stickers became stickers," meaning that the patients remained under observation until recovery was complete. Those who did wander, as such people invariably do, only required to have an adherent dressing torn off an unhealed wound in some other clinic, or elsewhere, and they came back without hesitation.

Boils and carbuncles furnished three essentials for study—viz., infection, suppuration, and necrosis. To make two boils grow where one grew before, or to make a ring of satellites about a centre, one had but to scratch the adjacent skin, cover with a flaxseed poultice, and leave the rest to nature. They prove to be excellent examples of local pyogenia, which was aggravated or endurable according to a bad or good bodily state. A number of able surgeons have considered that the application of a chemical antiseptic to an infected wound is of small value; to this I agree, at least to this extent: In my experiments any antiseptic which would not arrest a boil was not considered worth trying in the depths of an infected wound, and its laboratory antiseptic index proved to be but a poor guide to its clinical employment, if its application irritated, and thus hastened, the course of a boil. To quote one of the House Staff: "If you get a boil with your antiseptics you get it quick, or you don't get it." His meaning is quite correct. Anyone who is treating an infection is either making it better or worse.

* Read at the 28th Annual Meeting of the A.A.O. & G. at Pittsburg, September, 1915. *American Journal of Obstetrics*, February, 1916.

Consumers of large quantities of cheese almost invariably went to the bad when they left the hospital for home. Both boils and wounds seem to resent this article of diet. Its heavy charge of nitrogen, or something else, acted disadvantageously despite all and numerous favourable reports upon its great food value. Lemon juice and orange juice were beneficial both locally and internally. Mineral acids, calcium sulphide, etc., gradually were supplanted by the old-fashioned syrup hypophosphite compound cum ferro, and this appeared to deserve the high repute in which it was held by our forefathers. When lemon juice with soda bicarbonate (or citrate of soda plus carbonic acid) stopped a boil after bichloride had scored a failure, then one was shocked, and the idea was brought home that possibly the "Antiseptic Index," as compiled from the findings of the test tube and Petri dish, might read backward when tried at the bar of clinical experiment and upon septic human flesh.

If the patient must return to a tenement house environment, before recovery is absolute, then the nearer the operator's incision approaches the vertical the better. Infected Pfannenstiel incisions proved slow of healing. Celluloid linen irritated tissues much more than plain material. Large sizes of catgut were a nuisance. The Pagenstecher ligature could usually be lifted up, the loop cut, and the whole pulled out; but the catgut, when macerated, would frequently leave unobtainable pieces behind. One woman said that the silkworm-gut stitches in her cervix had been there for a year. They were removed, and apparently had not caused any trouble. Union was good. Two laparotomies cast out silk stitches months after an apparent healing. Finer or firmer cicatrices could not reasonably be expected. Wounds with their blood-vessels ligated with catgut and the whole closed with silk in every instance showed deep infection first, and presumably it started in the catgut, but whether the catgut was plain or antiseptic there was no way of determining.

Tracing the source of things with patients coming from different hospitals, cities, and states, proved futile and was early abandoned. This paper gives findings, merely. The use of absorbent suture material is something each operator must settle for himself. I am using catgut, but am also looking for the arrival of a day when its use will be abandoned, possibly with the same rapidity which marked its adoption. If linen thread is treated by frying at 340° F. or over, or small-sized catgut is immersed in biniodide of mercury, iodide, glycerine, and alcohol for thirty or forty days, there is no fear of their containing germs. It may be easily anticipated that those germs which can withstand boiling, in spore form, do not withstand an additional 130° of heat. All stitch fistulæ and post-operative herniæ followed the use of catgut, the all but universal use of which rendered contrast with other material impossible.

Three things tended to prevent primary union—(1) stitch traction with more or less necrosis; (2) irritation, including the caustic and tanning powers of iodine; (3) healing tissues are embryonic and fair game for infection or malignancy.

As to the first. It is hard to understand why someone has not used Dr. Alfred H. Gould's reverse mattress stitch to close fascia or aponeurosis. (1) The needle is inserted twice toward the incision and twice away from it. The result is a sort of square purse string that will not pucker, but pulls flat. In other words, it is a perfect reinforcement to the central stitches.

In regard to No. 2. Let anyone make two cuts

or incisions, paint one with tincture of iodine and the other with boiled water. Barring infection, that person will discover that the iodine test does very well indeed if it only takes twice as long to heal as the other. Iodine tanning is something like the mechanical device called the pulley—speed is sacrificed for efficiency. Suppose water containing 20 per cent. of glycerine be used to dilute the tincture of iodine to 1 dr. of the latter in 1 oz. of the mixture, then we find the tissues no longer becoming stiff and friable after its application. Suppose, again, that we have added calomel 1 part to tincture of iodine 1,000 parts. Just what the chemical result is, is a matter of difference of opinion on account of the presence of potassium iodide. It has been called biniodide of mercury, a tetraiodide, etc., but the germicidal power is increased tenfold for clinical or wound work and twentyfold for laboratory or test-tube work. This does not mean that it is inefficient in weaker solutions, because it is efficient, but the figures are easy and convenient to use. Let the skin wound be filled with the aforesaid solution just before fastening the subcutaneous stitch. Then fasten that stitch, wash all off with a saturated solution of perborate of soda and make the outlook for primary union excellent.

Some wounds refuse to heal until peroxide cleansing is discontinued. The offending element in the commercial solution of peroxide appears to be sulphuric acid, a preservative addition. At least, dry, red-edged wounds are sequential upon the application of dilute sulphuric, and absent when the H_2O_2 solution is neutralised with bicarbonate of soda.

Patients, said to be 95 per cent. well when sent home from various hospitals, had applied iodine or peroxide, or both, for various periods up to 90 days, and then they came into my hands with skin tanned or destroyed, with the depths of their wounds furnishing a purulent discharge or with gaping cuts filled with fungoid granulations. *Prima facie* appearances warrant the query: "If no antiseptic had been employed would the ultimate results not have been better?" It is easy to fill a wound with the peroxide solution and, upon a probe introduced right through the bubbling mass, obtain vigorous cultures. The solution is only a cleanser and, if neutralised just before using, does not do much damage. But ask any genito-urinary man what a pleasant time he has in cleaning up after a general practitioner has thoroughly and persistently used H_2O_2 in the male urethra. Ask him which has made that urethra the sorer, the remedy or the infection?

A chemist, engaged in the manufacture of bleaching materials, brought to my office everything he required to make peroxide. We spent three evenings in our endeavours to sterilise our purposely contaminated hands. We did not find any appreciable difference between tests and controls when our cultures were developed. But we did run the strengths of our solutions up to the limits of our skin tolerance; the bleaching power was good, the antiseptic influence nil. Cleaning up an iodine-painted wound with H_2O_2 does make for healing by washing away the excess of iodine, not otherwise.

As to statement No. 3. Immediate union is probably impossible of acquirement, but the chances of its occurrence are increased if the dresser is as careful in his *technique* as was the operator. Lymph coagulated by iodine may form a shield, but not a union any more than lymph, entangled in the meshes of gauze and then torn off, can make a true seal for any wound. Attempts at a sepsis which are not backed up by a trained and disciplined staff working with intelligence, in a favourable environment, are delusions, snares and myths. Antisepsis

(1) See "Operations on the Intestines," page 85, for description.

may be brought about by clumsy or careless fingers. Asepsis never can be unless by pure chance. In short, the precautions of the dresser must never fall below the level of the operating-room standard; or if they do so fall, asepsis should be abandoned and antiseptics initiated.

Packages of wipes of the usual size may be fried for twenty minutes, laid on a sterile tray, and only unwrapped after the operation is completed and the final wound cleansing with perborate of soda is begun. Then any number of such sterile (175° C.) wipes may be placed in contact with and about the closed and cleaned incision. Powders, such as thymol iodide (aristol), are neither necessary nor objectionable, and the wound may be left undisturbed until the eleventh day; or, inasmuch as the fried gauze does not stick nor its removal tear off the scab, the dressings may be removed and the wound dressed with the iodine, calomel, glycerine solution on the third, fifth, seventh, ninth, and eleventh days. The former is good, though called the "lazy man's way"; the latter gives equal results because of the non-adherent bandage. Choice seems a matter of indifference and union is obtained with either method. Because iodine is widely used, I wish to know the best way to use iodine, but far be it from me to blow a trumpet for iodine. Nor do I expect anyone to admit that his results are any better to-day than they were in his pre-iodine days. The men who are using iodine are so wedded to it that the suggestion of any other substance might involve a neglect of the powerful factor of personal equation, which makes a first-class man, using a familiar but second-class method, more than equal to a second-class man employing unskillfully a first-class method. Perhaps the answer to all such questions may be found, as suggested elsewhere, in experimentation with boils rather than with test-tubes.

A mere surface disinfection and healing may permit the disadvantage of an unchecked germ propagation in the depths of a wound. A non-fistuloid and altogether better condition of affairs would be obtained by maintaining an open wound from the very start. Chemistry is not our only guide. Dr. Sexton had any number of infected vaccinations in the Willard Parker Hospital, and found the local application of bacterins the very best method of treatment. This works well upon septic wounds, but the cost prevented my making more than a few dozen applications (exact number, seventy-five).

Allantoin is wonderful as a wound healer, even though not at all a chemical antiseptic. Its employment is simply a putting of the active principle of embryonic tissue upon embryonic tissues. It acts as though it made the wound furnish its own antibodies and thus clean itself. Strange to say, irritation or its absence does not sum up the whole matter, for 1 to 3,000 of nitrate of silver either in kaolin or water is an irritant antiseptic, and yet, at the same time, a stimulator of the healing processes.

Summary.—Fried ligatures, drains, pads, etc., do not adhere to wounds.

The non-adhesion allows of unlimited wound inspection and fosters healing.

The best way to treat wounds may be easily discovered by experimentation with boils.

If one wishes to use iodine, add calomel 1 to 1,000 to the tincture, and 1 dr. of this mixture and an equal part of glycerine to 1 oz. of water. This will prevent tanning and will permit penetration of the tissues.

If the patient has iodine idiosyncrasy, or if for any reason the wound does not do well, then abandon iodine at once and substitute 11 to 5,000 nitrate of silver or anything else that you deem its equal.

There is just as much difference in the wound healing of two different patients as there is in two pneumonias, two typhoids, or two gout.

Routine treatment may be all right, but frequently it is not; therefore, if the patient is to use H₂O₂ plus iodine, the results to be anticipated from his, or her, own personal application are either good or deplorable; there seems to be no middle course.

TREATMENT OF NERVOUS DISORDERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with much interest Dr. Percy Lewis's article in *THE MEDICAL PRESS AND CIRCULAR*, March 1st. I can cordially agree with practically every word he says, and venture to say that, in addition to the omissions he points out, I find neurologists sternly ignore, as a rule, the great benefits that may be procured by active treatment of the back along the spinous processes of the vertebrae and on each side of them. Some time ago a neurologist showed a patient at a meeting at which I was present. The case was one of disseminated sclerosis of the spinal cord. Considerable improvement in muscular power of the limbs had been secured by massage *to them only*. I asked if the back had been specially massaged, but the answer was "No." In the *Medical Times*, October-December, 1914, I published an article entitled "Continuous Counter-Irritation in the Treatment of Nervous and Other Diseases." I enclose a reprint, and you will see that in the first few pages I express views which very closely fit in with those of Dr. Lewis. I shall be pleased to send a copy of the reprint gratis to any of your readers on request.

I am, Sir, yours truly,

W. J. MIDELTON.

Bournemouth, March 22nd.

[We are well acquainted with the work of Dr. Midelton, and can support his claim that his views and those recently expressed by Dr. Percy Lewis are very similar.—ED., M.P. and C.]

IRISH COUNTY COUNCILS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Practically all the medical men outside two or three big towns are shut out of our County Councils by an illegal regulation of the Local Government Board. I appeal to the profession to support me in an application to the Courts to deal with this invasion of our elementary civic rights. Our impotence in season and out of season is all due to our non-assertion of our civic claims. Why do we not take a lesson from the lawyers?

I am, Sir, yours truly,

THOMAS LAFFAN.

Cashel,

March 22nd, 1916.

THE PSYCHOLOGY OF THE CONSCIENTIOUS OBJECTOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to Dr. T. Claye Shaw's article on "The Psychology of the Conscientious Objector" in the March 22nd *MEDICAL PRESS AND CIRCULAR*, is he not taking science over its boundary and into the region where it "won't work"? For when so learned a gentleman says

that there is "no such faculty" as "conscience," "moral sense," or "instinct," the defence of such a statement is likely to land him in hopeless difficulties. May I ask why he wrote this article? Surely it was not to get a page in your valuable journal, but because his "conscience" or "moral sense" urged him to state opinions of the conscientious objector which he considers are correct.

I am afraid that Dr. Clave Shaw, like many others, is giving an opinion of these people based on what people consider them to be instead of what they really are—viz., a deeply spiritual, clear-minded lot, who act on their reason and "moral sense" rather than on their emotions, and who object to taking any part in murder, and cannot see that because murder is organised and sanctioned by the law of the land that it is less ungodly.

We—yes, *we*—who are perhaps members of the Society of Friends, progressive thinkers or Socialists, etc., as well as our professional calling or trade participants, are making a stand against this wholesale orphan-producing, cruelty-concocting machine by absolute refusal to taking any part in it.

I, myself, am on the verge of possible punishment for taking this stand, but that in no way reduces my determination to obey my "conscience" and "moral sense" rather than man-made laws.

It is unusual, I know, for anyone other than qualified medical gentlemen to write to you, Sir, but as this is a question that directly concerns the persons known as "conscientious objectors," I am taking the liberty.

I am, Sir, yours truly,

Cotham, Bristol.

G. PERCY BIGGS.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

OPHTHALMOLOGICAL SECTION.

MEETING HELD MARCH 22ND, 1916.

SIR ANDERSON CRITCHETT, Bart., C.V.O., in the Chair.

COLONEL LISTER, A.M.S., C.M.G., and Lieut.-Col. GORDON HOLMES, M.D., R.A.M.C., read a paper entitled

DISTURBANCES OF VISION FROM CEREBRAL LESIONS, WITH SPECIAL REFERENCE TO THE CORTICAL REPRESENTATION OF THE MACULA.

THE authors stated that in their work at the base hospitals in France during the past eighteen months they had observed a very large number of cases in which the vision was affected by lesions of various portions of the optic system, but the time and opportunity afforded have not been sufficient for careful and complete examination of all. Hence, in some cases of considerable clinical importance only scanty and incomplete notes had been secured. Still, by selecting for thorough examination a certain number of suitable cases, a group of facts had been collected which had an important bearing on the cerebral localisation of vision, more particularly on the representation of different regions of the retina in the cortex. It might be objected, say the authors, that as the observations were, necessarily, made at an early stage after the infliction of the injury, some of the effects observed may have been due to functional disturbances, rather than to local injuries of the corresponding cortical areas or their centripetal fibres. But if it could be shown that there was a constant relation between the probable site of the injury and the form of the visual defect,

certain general conclusions would be at least justifiable.

The injuries in the cases referred to included penetrating and perforating wounds of the cranium by rifle bullets, shell fragments and shrapnel, as well as local concussion and depressed fractures. They remarked on the striking rarity of superior quadrantic hemianopia in gunshot wounds of the occipital region.

The authors point out that in over two thousand cases of head injury they never saw a central scotoma when a direct injury of the occipital poles could be excluded, and they regard this as striking evidence that central vision is represented on either or both, the mesial or the lateral surface of the posterior borders of the occipital lobes. And the observations conformed to the general view that the visual area corresponds with, or at least includes, the area striata.

The interesting question is raised in the paper as to whether vision for colours may be dissociated from that for white: in other words, whether an achromatopsia can be produced by cerebral lesions. They consider, however, that they have gleaned no conclusive evidence that achromatopsia, with intact vision for white, is produced by cerebral lesions which involve either the cortex or the optic radiations.

The authors' conclusions, which they do not yet regard as final, are formulated as follows:—

(1) The upper half of each retina is represented in the dorsal, and the lower in the ventral, part of each visual area.

(2) The centre for macular or central vision lies in the posterior extremities of the visual areas, probably on the margins and the lateral surfaces of the occipital lobes.

(3) That portion of each upper quadrant of the retina in the immediate neighbourhood of, and including the adjacent part of the fovea centralis, is represented in the upper and posterior part of the visual area in the opposite hemisphere, and *vice versa*.

(4) The centre for vision from the periphery of the retina is probably situated in the anterior end of the visual area, and the serial concentric zones of the retina from the macula to the periphery are probably represented in this order from behind forwards in the visual area.

The contribution concludes with a grateful acknowledgment of the assistance received by the authors from the medical officers of the various hospitals in which the cases were observed, and their thanks to Captain Curtis Webb for help in the preparation of the illustrations.

THE CHAIRMAN, in expressing the gratitude of the Section to the authors for their painstaking research, referred to the rapid strides made by brain surgery, and the unexampled opportunities afforded by the present conflict to make advances in surgical and medical knowledge.

Lieut.-Col. ELLIOTT asked whether Colonels Lister and Holmes were able to confirm the estimate as to the efficacy of the steel helmet in preventing head injuries. He also referred to the greater severity of wounds inflicted by bullets which struck in the first 250 yards of their flight, before they had settled down to a steady onward course, as compared with those which found their billet at distances between 250 and 1,000 yards.

Captain ORMOND suggested a possible confirmation of the authors' thesis in the central scotoma met with in some people who were subject to megrimous attacks. It was probably a vascular phenomenon, dependent upon the macular centre being placed at the posterior pole of the occipital lobe.

Mr. LESLIE PATON urged ophthalmologists in this country who received cases from France after the shock and the acute symptoms had subsided, to exercise great care in the taking of the fields of vision and the construction of perimeter charts (though not with the McHardy perimeter), and follow the cases up as far as possible, keeping a record of their sequelæ, and in that way assist in making the investigations of Colonel Lister and Lieut.-Colonel Holmes of abiding value.

Mr. J. H. PARSONS agreed with Mr. Paton, and asked that when ophthalmic cases were sent over, the notes of the cases should accompany the patients.

Col. HOLMES briefly replied, remarking that as the steel helmets had only recently been issued to the British Army it was as yet too soon for conclusions to be drawn.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, FEBRUARY 11TH, 1916.

The President, GIBBON FITZGIBBON, M.D., F.R.C.P.I., in the Chair.

UTERINE SARCOMA.

THE PRESIDENT showed a uterine sarcoma removed from a patient, æt. 51. There had never been any menstrual abnormality, and the menopause occurred between 45 and 46 years of age without incident. Five months before operation the patient developed uterine hæmorrhage, which came on regularly and frequently, and for five weeks had been continuous; the only other symptoms were due to the pressure of the tumour in the pelvis. On examination a symmetrical tumour was found reaching nearly to the umbilicus, and suggesting fibroid of the uterus. Total hysterectomy was performed. On opening the uterus the cavity contained a pure white lobulated mass, brainlike in consistence, the centre of which contained blood-clot. Microscopically the tumour was a round-celled sarcoma. He referred to another case of fibro-sarcoma removed from a girl, æt. 27. Both tumours were cystic. It was not possible in either case to diagnose sarcoma as distinct from fibroid before removal, though at operation the probability was suggested by the softness of the tumour in the case shown and by the impossibility of enucleation in the other case.

Dr. ALFRED SMITH stated that his experience was that pain seldom occurred in the early stages of diffuse sarcoma, but it was an early manifestation in fibro-sarcomata. He recalled cases of polypi projecting through the os in which pressure of the examining finger burst a thin limiting membrane which formed the capsule of the polypus. The presence of this membrane he considered characteristic of sarcoma.

Dr. ROWLETTE considered that the tumour originated in the endometrium; this form was most frequent in his experience.

Dr. SOLOMONS said that although text-books referred to sarcoma as a disease of early life, the experience in this country was that it occurred most commonly about or after the menopause.

EXHIBITS.

Sir A. HORNE showed (1) surgical needle removed from perineum; (2) fibroma with double pyosalpinx.

Dr. HASTINGS TWEEDY remarked on the very small size of the needle which had been employed to stitch the perineum. Its great delicacy proved

the undoing of the doctor who used it. It was no surprise that it should have broken, but it was a surprise to find that there was at present a practitioner who believed that any successful results could be achieved by superficial stitching with a diminutive needle.

Dr. ALFRED SMITH said that the case of double pyosalpinx raised the important point as to the period after infection at which it would be safe to operate. Sir A. Macan taught that the tube contents became sterile twelve months after infection. His (Dr. Smith's) rules for operation were as follows:—A period of at least three months must have elapsed from the date of infection; the temperature must be normal and the tubes mobile; there must be no rise of temperature following a bimanual examination.

ABDOMINAL PREGNANCY.

Dr. SOLOMONS recounted the history of a case of the above in which he concluded that the cause of the condition had not been established, that diagnosis was extremely difficult, and that the best treatment was to operate immediately the case was diagnosed.

Dr. ALFRED SMITH recalled a case which had occurred in his practice. The danger from hæmorrhage in separating the placenta was very great. He suggested the advisability of primary ligation of the corresponding internal iliac artery before proceeding with the separation of the placenta.

Dr. HASTINGS TWEEDY said that in view of the operation described in his paper by Dr. Solomons, and a specimen shown previously by the President, Dr. Gibbon FitzGibbon, he thought the time had arrived to review preconceived impressions respecting the fear of operative procedure in abdominal pregnancy. He thought with Dr. Solomons that the proper way was to tie off all vessels which fed the placenta, dealing with them one by one as they came into view, rather than endeavouring to ligate some large artery which might theoretically be supposed to feed all the placental branch vessels.

Dr. SOLOMONS, in reply, said he did not think that Dr. Smith's proposition to ligate the internal iliac artery would be advisable or useful. He thought the best plan was to separate the placenta and to tie off vessels as each appeared. The severity of the hæmorrhage in the case described in his paper was such as to cause marked constitutional symptoms. The amount of liquor amnii was small.

TWO CASES OF INTESTINAL HÆMORRHAGE IN THE NEW-BORN.

Dr. MABEL CRAWFORD described two cases of the above. Her paper will be found on p. 283.

Dr. HASTINGS TWEEDY said that infantile hæmorrhages were almost always due to duodenal ulcer, and Dr. Crawford's suggestion as to the ætiology was of interest. Against her theory, however, it might be urged that digestive juices were not present in a newly born infant's stomach, nor were they found there for many hours or days after birth. This argument could no doubt be countered by a suggestion of precocity in the formation of the gastric ferment. The subject needed much further investigation, but the treatment of the condition by horse serum in large doses seemed up to this to have yielded the most satisfactory results.

Dr. TREVOR SMITH said that he did not think the dose of adrenalin mentioned by Dr. Crawford sufficient. He wished to know if calcium chloride was given to either patient. He had a case of the kind a few years ago, and upon the administration of the latter drug the hæmorrhage ceased.

Dr. SOLOMONS asked whether there had been difficulty in labour in either of the cases, as

dystocia was a common cause of melæna. He considered that hæmorrhagic stools were caused often by other factors than duodenal ulcer, and that surgical interference in most cases would be futile. Cold applications to the abdomen and the injection of cold water per rectum had been successful in some instances.

Dr. ROWLETTE referred to intussusception as a cause of intestinal hæmorrhage in the new-born.

The PRESIDENT referred to a case of epistaxis in an infant three days old. The child died three hours after the first bleeding. It was pale and languid. Ecchymosis of the soft palate and fauces were noted, and, although the evident loss of blood was very slight, the case suggested severe internal hæmorrhage. He thought these cases were not all due to one definite cause, such as duodenal ulcer, but that the bleeding might occur from any part of the alimentary mucous membrane.

Dr. CRAWFORD said, in reply, that as to the cause of the ulceration she regarded it as chemical rather than infective, because of the very early formation of the ulcer. The secretion of gastric juice before the third day would certainly be abnormal, but this would account for the rarity of duodenal ulcer. As to treatment, she could not approve of cold applications on account of the general condition of the infant. She had not given calcium chloride. She quoted two other cases which had recovered after treatment with serum.

LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD TUESDAY, MARCH 21ST, 1916.

The President, DR. J. L. BUNCH, in the Chair.

THE PRESIDENT showed, among others, the following case:—A Belgian man, æt. 43, with a mixed large and small follicular syphilitic eruption on the trunk, of 3 to 4 months' duration; the patient also had an atrophic scarring on the left eye, caused by a shell during the siege of Antwerp: a most successful transplantation had been performed in this region.

Dr. MORGAN DOCKRELL showed a case of idiopathic multiple hæmorrhagic sarcoma which had greatly improved under thyroid extract and streptococcal vaccines; also a case of perforating ulcer in a man æt. 36, who had received nine injections of salvarsan without any appreciable result. The condition was steadily improving under mercurial treatment.

Capt. W. GRIFFITH showed a case of pustular folliculitis affecting the legs and thighs, and which had been treated by Simpson's rays. After eight exposures the condition cleared up, but a few days later there was a pronounced recurrence of the eruption.

Dr. W. KNOWSLEY SIBLEY showed the following cases:—(1) A girl, æt. 16, who had a rather unusual ulceration on the fronts of both legs, due to sitting before the fire. (2) A case of psoriasis figurata in a recruit. The eruption was particularly well marked on the back, and had been present for six years. (3) A woman, æt. 28, with a chancre on the lower lip, followed by a secondary eruption on the trunk.

Major E. G. FFRENCH showed a case of strumoderma in a youth, the lesions occurring on the face and neck, and which has been somewhat improved by applications of Simpson's rays.

Capt. C. H. MILLS showed a case of syphilis on an old-standing psoriasis; the patient also had a peculiar horny growth on the umbilicus.

The President's paper, entitled "Dermatitis due to Hair Dyes," was postponed until the April meeting.

OBITUARY.

DR. JOSEPH BARNICOT, B.A., M.D., M.R.C.S., L.R.C.P., HITCHIN.

THE death is announced of Dr. Joseph Barnicot, of Hitchin, Hertfordshire, from typhoid fever, on March 10. Born in 1875, he was educated at Marlborough, Pembroke College, Cambridge, and St. Thomas's Hospital, while he also studied at the Rotunda Hospital, Dublin, but after obtaining his B.A. degree at Cambridge in 1896 he spent some time in travelling abroad. In 1902 he took the M.B., B.C. degree at the University of Cambridge, and also the M.R.C.S., L.R.C.P., while directly after qualifying he was appointed assistant house surgeon at the Huddersfield Infirmary, and subsequently held the senior post. In 1905 he took the M.D. degree at Cambridge, reading for the purpose an excellent thesis on the Iodine Reaction in the Leucocytes, which work was carried out at Cambridge and in the pathological department at St. Thomas's Hospital. In 1906 he set up in practice at Hitchin. There he had built up an excellent practice at the time of his death. He was twice married, and had by his first wife one son, and by his second wife two daughters.

DR. ANDREW S. WALKER, M.A., M.D. Edin.

DR. ANDREW SCOTT WALKER, of Ordsall Rectory, Retford, died on Sunday at a nursing home in London. The deceased had been in indifferent health for a long time, but his death was rather sudden. He married a sister of Mr. C. W. Keyser, of Eaton Hall, Retford, and went into the Retford district about twenty-four years ago.

Deceased, who was fifty-one years of age, was formerly a well-known medical practitioner in Sheffield. His health broke down some years ago, and he had to give up his Sheffield practice.

Dr. Walker was a native of Bliebo Craigs, near Cupar, Fifeshire. He received his medical education at Edinburgh University, and qualified M.B., C.M., in 1892, and M.D. (Gold Medal) in 1895. He held there successively the appointments of house surgeon at the Royal Maternity Hospital, Physician at the Women's Dispensary, Assistant-Physician for Diseases of Women at the Livingstone Memorial Dispensary, and Assistant-Physician of the out-patient department at the Edinburgh Royal Infirmary. His first practice was in Sheffield, to which city he removed in 1894.

DR. LEON LABBE, PARIS.

DR. LEON LABBE, member of the Academy of Medicine and the Academy of Sciences, and Senator for the Orne, died on March 21 at the age of eighty-three. Dr. Labbé was one of the masters of French medical science. He was made Commander of the Legion of Honour in 1891.

DR. J. H. NAYLOR, L.R.C.P. EDIN., M.R.C.S. ENG.

DR. JOHN HOLLIDAY NAYLOR, who has died at Harrogate, in his 55th year, was a well-known practitioner in Leeds for about 30 years. About two years ago his health broke down, and after a winter in Surrey he had lived in retirement at Harrogate. Educated at Leeds, he qualified L.R.C.P. Edin. and M.R.C.S. Eng. in 1883. After acting as house surgeon at Leeds Infirmary, and at Clayton Hospital, Wakefield, he conducted a large practice in Leeds. He leaves a widow and a young family of one boy and two girls.

MR. WILLIAM JAMES MALLETT, M.R.C.S., L.S.A., of Oxford Road, Manchester, consulting surgeon to the Chorlton-on-Medlock Dispensary, left estate of the gross value of £10,760, of which £10,336 is net personally.

COLONEL ERNEST OCTAVIUS WIGHT, R.A.M.C., Assistant Director of Medical Services in Flanders, left unsettled estate of £1,953.

SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

High Degrees of Heat versus Low Degrees as Palliative Treatment of Advanced Carcinoma Uteri.—Boldt (*Amer. Jnl. Obs.*, lxxiii., 1) compares the results from the two methods, and reports a fatal case upon which an autopsy was made, and the effects of the treatment examined. The palliative cautery treatment was done with low heat applied for two hours. Two months later the cauterised surface felt smooth, but the tumour mass was larger than before operation; a second application was made with low heat for two and a half hours. The patient died of sepsis on the eighth day. *Post mortem* it was found possible to pass the finger from the vagina into the bladder, and from the bladder into the uterus and directly into the peritoneal cavity. Microscopically, the destruction of the cancer cells was practically limited to the necrosed zone, thus showing that the belief that low heat over a long period extends for any considerable distance is erroneous, and the effect upon the cancer cells was little, if anything more than upon the normal parenchyma. The author says he has not seen a single instance of cure following cauterisation. The only valid objection to high degrees of heat is the smoke and odour, but the operation can be effected in twenty minutes. The method of application of high heat is described. A dull heat is used at first, until a layer of carbonisation is formed, and then the electrode is raised to a light red. The application is controlled by a hand of an assistant in the abdomen. The suggestion to tie the internal iliac arteries before cauterisation is thought good. With cooling specula no damage can be done to the vagina or urethra. It takes about two weeks for the eschar to be thrown off, and then a short application of low heat for twenty minutes is thought good to stop any possible bleeding. F.

Contraction Ring Dystocia.—Harper (*Amer. Jnl. Obs.*, lxxiii., 1) considers this condition a definite entity, and from the study of ten cases thinks that premature rupture of the membranes, irritating intra-uterine manipulation, and oxytocic agents may be causes that may occur in a normally innervated uterus. Persistent recession of the presenting part occurred in four cases due to the contraction ring. It is pointed out how the retraction ring, being either in front of the presenting part or the shoulders, must by contracting push the part upwards unless the contractions of the fundus are sufficient to force the part through the ring, in which case the dystocia would be overcome. The diagnosis depends upon examination, the only symptom being obstruction, and treatment should be conservative delivery. F.

Toxæmia of Pregnancy.—Moulden (*Amer. Jnl. Obs.*, lxxiii., 1), in the study of 100 pregnancies in private practice, concludes that 95 per cent. gave a history of fæcal stasis, even judged by the opinion of the laity. On first examination the colon was nearly always full. Morning sickness was present in practically all cases, with the exception of five patients, who had been previously instructed to keep the bowels regular, and as a rule it improved or disappeared when proper colon evacuation was established. About 25 cases showed albumin in the urine at some time. Fæcal stasis may be looked upon as a common condition in all pregnancies, and since the excretory functions are called upon to excrete foetal waste products in addition to those of the ordinary non-pregnant state, many women who are well at other times may suffer from the retention during pregnancy. The one point common to all toxæmias is auto-toxæmia from fæcal stasis, and when it is recognised that fæcal stasis is common amongst

women it is not surprising that some organ or system sometimes gives way when the foetal excretion is superadded. A classification of toxæmia should begin with headache, irritability, malaise, and all the other minor ailments of pregnancy at the beginning as the most common forms, and ending, with the severe toxæmias, such as eclampsia, but all being of the same type, and largely due, primarily in any case, to fæcal stasis. F.

Value of Pituitary Extract in Obstetrics and Gynecology.—Bandler (*Amer. Jnl. Obs.*, lxxiii., 1), in a eulogistic paper, holds up pituitary extract as probably the most effective drug introduced into the practice of midwifery, and advocates its use in almost every condition which has been looked upon up to the present as unsuitable, but he strongly urges that the proper dose is not an ampoule merely because the drug is supplied thus. He prefers a third of an ampoule repeated every half hour, if the first stage progresses too slowly, with membranes unruptured and cervix not dilating fast enough, or when the head is fixed and well moulded and through the brim, but the cervix is not dilated at all. Dry labour has not been considered a complete contra-indication in the first stage. When patients complain of pains, and they are probably false labour pains, pituitary extract will have the effect of establishing regular good pains. In induction of labour, after the bag has been introduced and the patient feels only indefinite discomfort, pituitary extract will, in small repeated doses, establish regular labour in a very much shorter time. Chloroform inhibits the drug, but can be used with advantage. It is also advised before Cæsarean section, in menorrhagia, and post-operative intestinal paresis. It does not act in the same way in all patients, and therefore the individual must be studied. F.

Injuries to Nerves.—Billington (*Birmingham Med. Review*, January, 1916) points out the great difficulty often met in determining accurately the nature of the injury done to a nerve by a gunshot wound. The efficiency of the treatment, and the ultimate result to the patient, however, depend to a great extent on the accuracy of the diagnosis. He recommends that a systematic investigation of the patient should proceed as follows:—Obtain an accurate history of the conditions under which the wound was received and its immediate effects. Carefully and methodically examine the distribution of the paralysis, motor and sensory, to determine whether it corresponds with the anatomical distribution of one or more nerves or a portion of a plexus, or whether it presents the phenomena of hysteria. Careful charts of sensory loss are more helpful than the presence of complete muscular paralysis and reaction of degeneration. The information given by electrical investigation is valuable but not wholly trustworthy. Patient investigation over a period of some weeks may be necessary to arrive at a correct diagnosis, but there is no certain evidence that reasonable delay militates in any way against operative success. Billington believes that an operation should never be undertaken until the wound is firmly healed. Sepsis is a complete bar to success. K.

Eye Strain.—Bray (*New York Med. Jnl.*, January 29th, 1916) discussing the connection between many gastro-intestinal symptoms and eye strain points out that failure of the ophthalmologist to give immediate relief to the patient must not be considered as conclusive proof that the symptoms are not due to eye strain. Refraction, it is true, is an absolute science,

applied refraction, however, or how to refract, is an art. In the application of the science of refraction as a therapeutic element difficulties arise. Great judgment and care are required on the part of the ophthalmologist, and this must be assisted by the intelligence of the patient. Bray further points out that it is often the minor astigmatic errors that produce the most annoying symptoms. K.

Treatment of Leprosy.—Heiser (*New York Med. Jnl.*, February 12th, 1916) records his experience in the Philippines of the treatment of leprosy by the hypodermic injection of chaulmoogra oil. It was found that the crude oil was more efficacious than the refined oil, but difficulty was experienced in getting the oil absorbed when it was injected hypodermically. This difficulty was overcome by mixing the oil with camphor. The preparation used was as follows:—

Chaulmoogra oil, 60 cc.
Camphorated oil, 60 cc.
Resorcin, 4 grams.

Mix and dissolve with the aid of heat on a water bath and then filter. The injections are usually made at weekly intervals in ascending doses. The initial dose is one c.c., and this is increased to the point of tolerance. Much difference exists as to the amount of the mixture which patients are able to take. In some a few cubic centimetres produce marked reactions in the lesions, accompanied by fever and cardiac distress. The object sought is to regulate the dose to prevent reactions of too violent a character. When Heiser left the Philippines in March, 1915, there were some 200 patients showing noticeable improvement. A statistical summary of the first series of nine cases gives the following results. Apparent cures, 11.11 per cent.; apparent clinical recoveries, 44.44 per cent.; showing marked improvement, 33.33 per cent.; showing only slight evidence of improvement, 11.11 per cent. Heiser draws the following conclusions from his experience:—The present stage of the development of the treatment does not warrant a claim that anything like a specific for leprosy has been found, but experience shows that chaulmoogra oil gives more consistently favourable results than any other treatment that has come to his attention, and holds out the hope that further improvement may be brought about. It produces apparent cures in some cases, causes great improvement in many others, and arrests the progress of the disease in almost every instance. The treatment is apparently equally efficacious in all forms of the disease, that is, the tubercular, or hypertrophic, the anæsthetic, and the mixed. K.

SPECIAL REPORTS.

NEW ADVISORY COMMITTEE ON DOCTORS' WAR SERVICE.

It is announced that the Royal College of Surgeons has joined the Royal College of Physicians in forming an Advisory Committee to assist the medical authorities at the War Office in their task of securing and selecting doctors.

The new Advisory Committee will work through the Central Medical War Committee, and will deal with:—

(1) Any case affecting the several metropolitan hospitals and medical schools during the war in respect of medical men on their staffs, including residential and teaching staffs—*i.e.*, any case with regard to whom the question arises as to whether he is indispensable or would suffer excessive personal hardship if required to enter military service.

(2) The case of any other medical man in England or Wales in respect of whom the Central Tribunal under the Military Service Act, 1916, or the Central Medical War Committee thinks it desirable that the Advisory Committee of the Royal Colleges should be consulted.

The Advisory Committee will, in the first place,

institute a survey of the minimum necessities of the several metropolitan hospitals and medical schools in respect of staff, and so will obviate the danger of depletion, while at the same time securing the supply of doctors needed by the Army.

The chief merit of the scheme as now produced is that it gives full weight to professional opinion. It is no hard and fast system of conscription, but a system designed to secure fair treatment and adequate compensation. Doctors will be relieved of the difficulty of deciding whether they should go or stay in civil practice; those who go will have their interests looked after; those who stay will still be afforded full opportunity of serving their country.

MEDICAL NEWS IN BRIEF.

Medical Sickness, Annuity, and Life Assurance Friendly Society.

WE have received a copy of the annual report of the above society for the year ending December 31, 1915, which is of a very satisfactory nature. The number of members has increased by seventy. The total of the Sickness and Accident Fund is £170,229 11s. 7d. During the year £19,975 18s. was paid away in sickness and accident benefit. There were 702 sickness and 91 accident claims. Of the latter twenty-four were motoring accidents, and sixteen poisoned wounds. There were seven claims for shrapnel or gunshot wounds received on active service. The Annuity Fund totals £78,609 16s. 6d.; the Life Assurance Fund £21,014 9s. 6d. The total interest received on all funds was £9,786, being at an average net rate of £3 18s. 5d. per cent. The society subscribes annually 100 guineas each to Epsom College and to the Royal Medical Benevolent Fund, and also subscribed ten guineas to the British Dental Association Benevolent Fund. As no agents are employed, and no commission paid on new business, a large amount of money is saved annually, which goes to the benefit of members.

New French Remedy for Syphilis.

At a meeting of the Academy of Sciences, Professor A. Laveran described a new specific for syphilis, the discovery of Dr. Danysz, of the Pasteur Institute, who claims that it is by far the most effective yet found.

The remedy is a preparation based upon a mixture of arsenic, antimony, and silver, which the discoverer has named "102," or "Margol." It is alleged to be twice as powerful as Ehrlich's "606," and quite harmless. Drs. Dalimier, Levy, and Franckel, who tested Margol, declare that they obtained remarkable results in even far advanced stages of the disease.

Germany's Falling Birth Rate.

OFFICIAL returns have now been issued of births and deaths in Prussia in 1914. The figures are very remarkable, and, as the population of Prussia is roughly two-thirds of the population of the Empire, the Prussian statistics are always a pretty safe guide. The number of births was in 1914 1,202,528, as compared with 1,209,500 in 1913, and the number of deaths was 802,776 as compared with 656,490, so that the excess of births over deaths was 399,752, as compared with 553,010. The number of marriages fell from 323,709 in 1913 to 286,197 in 1914. Between 1904 and 1913, the excess of births over deaths fell from 562,508 to 399,752. In these ten years there was a reduction of the birth rate by about 20 per cent. and a reduction of the death rate by only six per cent.

Scottish Hospital for Limbless Heroes.

A HOSPITAL for Scottish limbless sailors and soldiers is to be opened in Glasgow, the military authorities having officially approved of the movement. Lord Provost Dunlop has already received generous financial support, the donations including two of £1,000 each.

Insurance Doctor and another's Panel Patient.

A COURT of Inquiry appointed by the National Insurance Commissioners, and comprising Mr. J. F. Williams (chairman), Mr. C. E. S. Flemming, M.R.C.S., L.R.C.P., and Mr. J. P. Williams-Freeman, M.D., M.R.C.S., sat at the Castle of Exeter yesterday to hear a complaint that Dr. J. H. Clements, a panel doctor at Winkleigh, issued medical certificates on Form 40 to John Fry, jun., North Tawton, the patient of another panel doctor (Dr. Langdon, now of the R.A.M.C., but formerly of North Tawton).

Mr. J. Radcliffe, barrister, appeared for the Devon County Local Medical Committee, and said the complaint arose out of the finding of the local Medical Committee, who passed a resolution declaring that what Dr. Clements had done was detrimental to the medical service, and suggesting that his name should be removed from the panel.

The main facts, supported by evidence, were not in dispute.

Dr. Clements, in his evidence to the Court, admitted that he issued a certificate to John Fry declaring that he was suffering from asthma and unfit for work. Fry told him he had been Dr. Langdon's patient for some weeks, and asked witness to treat him as a private patient. Witness replied that he did not care about attending him as a paying patient, as it was not his rule to attend insured persons and charge a fee. Witness was willing to give him his services during his present illness if he could not obtain relief from his own doctor. Witness was not charging any fee, and Fry, when he was well, could, if he liked, go back to his panel doctor. He (witness) had a panel of his own of about 400. He added that for months he had been under a cloud, the British Medical Association having cast aspersions on him. A more cruel charge with regard to Fry could not be imagined.

The chairman intimated that the Court would report the case to the Insurance Commissioners.

Balances owing to Panel Doctors.

CONSIDERABLE unrest prevails among Lancashire panel doctors over the balances due to them for 1914 not having been received yet, stated Dr. Oldham, at Monday's meeting of the County Insurance Committee at Preston. He suggested that each doctor should be sent a statement of how he stood with the committee for the period January, 1914, to December, 1915, showing payments made to the doctors and amounts still owing.

Dr. Oldham instanced cases of hardship through not getting the money owing. One doctor on entering the panel had to buy a motor car, engage a chauffeur, and go to other expenditure which left him now £400 in debt. Unless he was paid the money due, he would have to borrow, or be pestered by "duns." In another case, the wife of a doctor now in the R.A.M.C. was under heavy expense in paying a locum, etc. The committee owed them £200, and to pay her way she had to entrench upon her savings. Dr. Oldham urged the committee to try to hurry up the Commissioners to find the money for meeting the debts.

Ultimately, Dr. Oldham accepted the offer to refer the matter to the Finance Committee.

Charing Cross Hospital.

A REPORT showing a highly successful year's working was presented, on March 23rd, to the annual court of the governors of Charing Cross Hospital. Princess Louise (the president) was unable to be present, and the chair was taken by Mr. George Verity, chairman of the hospital, who stated that the accommodation was now 300 beds, which meant that the building was being used to its utmost capacity. The equipment was now second to none. The X-ray department had been brought up to date, and it would bear comparison with any similar hospital department in the world. The old mortgage had been reduced from £85,000 to £50,000. The cost of provisions, coal, gas, etc., was dreadful. They had to

remember, however, that 747,000 meals were provided in a year, and he could promise the subscribers that the value was got for every penny of expenditure.

Exactly half the beds, the chairman continued, were available for soldiers and sailors, and the efficiently-organised convalescent service had enabled the beds to be cleared rapidly. In "after care" work it was the boast of the hospital that not one soldier had left who required an artificial limb or employment who had not been provided for. The tuberculosis dispensary was now established, and the attendances had been made at the rate of 2,500 per annum. In that work the hospital were asked to co-operate with the Westminster City Council, but the conditions of the agreement offered would have destroyed the discipline of the hospital. It had therefore been decided not to go on with the agreement, although the work of the dispensary would be continued. That, however, was not likely to prevent the Westminster City Council from entering into competition with the hospitals at a time when everyone was advised to save.

Poplar Hospital.

Mr. J. G. BROodbANK presided at the annual meeting of Governors of the Poplar Hospital. The annual report, which covered the diamond jubilee year of the hospital, said the past year had closed with a record sum to their credit. The income for the year was £19,858, by far the largest ever received except in 1910, when the amount of £20,683 included a legacy of £6,000. In-patients admitted during the year had gone up from 1,570 to 1,642. Out-patients and casualties numbered 41,042, a decrease of 5,557. New out-patients, however, had increased from 3,579 to 4,667, and their attendances numbered 19,728, compared with 16,285. Out-patients and casualties totalled 67,705, the complete total of attendances in all departments being 71,509. In addition to the wounded soldiers admitted as in-patients, 480 had been treated in the casualty and out-patients' departments. The report was adopted; a vote of sympathy was passed with Lady Knutsford on the serious accident to Lord Knutsford, who is chairman of the hospital, and the thanks of the Governors were accorded to Lord Inchcape, who presided at the meeting in the City last December, when the record sum of £7,000 was collected.

Italian Hospital.

IN the absence of the Italian Ambassador, Prince Borghese, of the Italian Embassy, presided, on March 22nd, at the annual meeting of the Italian Hospital in Queen Square, and moved the adoption of the annual report.

Sir Stuart Coats (chairman of the committee), in seconding the motion, said at the commencement of the war they had set aside twenty-five of their fifty beds for sick and wounded soldiers and last October they had, at the request of the War Office, found room for another thirty-five beds, still keeping twenty-five for civilian patients. They had at first received a number of Belgian soldiers, and afterwards many British soldiers; and he was glad to testify to the excellence of their conduct and the gratitude they evinced for the care bestowed upon them. The hospital was a connecting link in the British capital between the two nations, which, happily, were now fighting together as Allies. The Italian Government were using the hospital for the attestation and medical examination of Italian recruits. It was with great pleasure that they had received a Christmas gift from Queen Mary.

Sir Dyce Duckworth, in seconding a vote of thanks to the Italian Government for their annual grant of £100, moved by Cav. Uff. R. Reitmeyer (hon. secretary), paid a high tribute to the administration of the hospital.

Last year the hospital treated 4,494 patients, of whom 721 were in-patients, 265 of these being soldiers. Of the civilian patients, 2,672 were Italian and 1,334 British, the remainder being of various nationalities.

Doctors and the Army.

IN the House of Commons, on March 23rd, Mr. Tennant replying to Sir P. Magnus, said that every

effort was made to employ gentlemen who joined the Royal Army Medical Corps in such a way as to give their individual qualifications every consideration. He must at the same time point out that it was sometimes not practicable to use their services exclusively in one special line of practice, as the need for special work was limited. His information was that these gentlemen willingly gave their attention to work outside their special qualifications when work of that kind was awaiting attention.

Sir P. Magnus also asked whether the Government would consider the advisability of reconstituting the Advisory Board to co-operate with the General Superintendent in the further organisation of the medical service; and, if so, whether he would have regard to the suggestion made by a number of medical men that such a board should include some lay representatives.

Mr. Tennant replied that he took note of the suggestion, but he could not admit that a case had been made out for interfering with the organisation as it at present existed.

Mr. R. McNeill: Is it not the fact that the Advisory Board was in existence when the war broke out, and that the neglect to call it together was without any proper authority?

Mr. Tennant: No, sir. I think my hon. friend is misinformed as to the facts. I gave him a description of what occurred at the outbreak of the war in the debate the other evening. It was quite within the competency of the military authorities to suspend the activities of the Advisory Board as and when they might think proper, but I think it is true that the Board had been sitting up to that time.

Sir P. Magnus asked the Under-Secretary for War whether he could utilise to a greater extent the services, in part-time work at hospitals or in looking after the health of the troops, of resident local practitioners, and so release a proportion of the men who had volunteered for whole-time service abroad, or had been asked to take commissions in the Royal Army Medical Corps.

Mr. Tennant: The policy suggested in the question is already followed. There is now a considerable number of medical practitioners employed in part-time work, and it is anticipated that this number will be largely increased.

Military Position of Dental Students.

MR. J. BROMLEY, Dean of Guy's Hospital, applied, at Southwark exemption tribunal, for exemption of fourteen dental students. He said that owing to the decrease in the number of dental surgeons, the hospital had had to close down part of its dental surgery, and to discontinue the treatment of children with malformation of the jaw. Most of the applicants were in their third year, and if they joined the Forces, they would have no chance to do any work in the Army of a dental nature. There was a limited number of dental commissions in the Army, and as the dental treatment of the Army was appalling there was a great outcry. They were hoping that more dental commissions would be granted by the War Office as a result of the present agitation.

All the students were granted six months' extension.

U.S.A. Expenditure.

STATISTICS prepared by Dr. Charles W. Eliot show that in the United States the yearly drink bill amounted to £440,000,000; tobacco, £240,000,000; non-intoxicating drinks, £24,000,000; patent medicines, £16,000,000; and chewing gum, £2,600,000.

Edinburgh Public Health.

THE report for 1915 of Dr. A. Maxwell Williamson, Medical Officer of Health for Edinburgh, contains some interesting statistics concerning the population of the city. The population of the registered area at the Census was 320,769; at June 30 last it was estimated at 328,493. The number of inhabited houses was 73,033, as compared with 72,523 in 1914. The total number of births registered in the city in 1915 was 6,112 giving a birth-rate of 18.6 per 1,000 of the estimated population. After the necessary

corrections have been made for transcript births, the number to be allocated to the city is reduced to 5,851, equal to a birth-rate of 17.8 per 1,000—the lowest ever recorded in the city. By way of further comparison, it may be stated that the rate per 1,000 in 1861 was 33.4; in 1871, 34.8, the highest recorded in the last fifty-five years; in 1881, 32.2; in 1891, 28.2; in 1901, 24.9; in 1911, 21.2; in 1914, 20.2. Of the total births last year 8.4 were illegitimate. There were 36 deaths reported last year from military quarters, two from pulmonary phthisis, nine from infectious diseases, and 25 from other causes. Under the heading of infantile mortality, it is stated that 774 deaths took place of infants under one year, or 132 per 1,000 births. The deaths among the population generally from phthisis numbered 372, equal to a death-rate of 1.1 per 1,000, being the same as recorded for 1914. Of the victims 103 were males and 179 females. The total notifications of and deaths from infectious diseases (except phthisis) in 1915 were notifications 3,037, and deaths 230, the latter (case and death-rate) equal to .70 per 1,000 of population, as against .35 for the preceding five years.

University of Durham.—Faculty of Medicine.

THE following Candidates have passed the first examination for the degree of Bachelor of Medicine:

Elementary Anatomy and Biology, Chemistry and Physics.—Honours, Second Class: Richard L. Dagger, Robson C. Brown.

Pass List: Tom H. R. Anderson, Neil R. Beattie, Dorothy O. S. Blair, Nan Coxon, Hugh L. Mather, Robert P. Wanless, Philomena R. Whitaker.

Elementary Anatomy.—Mark J. Erdberg, M.Sc., Knn Piu Leung, May Raw, B.Sc., Robert Sanderson, B.Sc.

THE following have passed the third examination for the degree of Bachelor of Medicine:—

Materia Medica, Pharmacology and Pharmacy; Public Health, Medical Jurisprudence; Pathology and Elementary Bacteriology.

Percy V. Anderson, Richard V. Brew, Hugh J. Dingle, Donald Henegan, William A. Hewitson, Charles G. Irwin, George M. Kerry, John K. R. Landells, Sadek Abdel Shehid, Iskander Soliman, Harold I. Sterne-Howitt.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations were granted the L.S.A. diploma of the Society, entitling them to practise Medicine, Surgery and Midwifery:—

J. Fox-Russell, H. M. Gray, and R. Milne.

MEDICAL WAR ITEMS.

LIEUTENANT NEIL MURPHY GAVIN, R.A.M.C., who was killed in France on March 12th, aged 42 years, was formerly a medical missionary at the Irish Mission Hospital, Anand, Bombay, under the Irish Presbyterian Church. At the outbreak of war he offered his services and received a commission in the R.A.M.C. He married Dr. Maud Muriel Stevenson, daughter of the Rev. Dr. Fleming Stevenson and also a missionary at Anand.

WITH reference to Captain H. B. Cunningham, M.B., whose name appeared in the official list of those wounded in the North of France, and who was at first supposed to be a Belfast surgeon of the same name and initials, this has subsequently been corrected to Captain Hugh Boyd Cunningham, of Sunderland. Captain Hugh Boyd Cunningham is the son of Dr. John Cunningham, of Sunderland. Before the war, Captain Cunningham was in practice in that town as an ophthalmic surgeon, and held the position of honorary surgeon to the Durham County and Sunderland Eye Infirmary. At the outbreak of hostilities he took a commission in the Royal Army Medical Corps, and was attached to the 3rd Northumbrian (County of Durham) Royal Field Artillery, Territorial Force. We learn that the wound is slight, and that Captain Cunningham is now on duty again.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE WELLCOME HISTORICAL MEDICAL MUSEUM.

We are asked to announce that this institution (54A Wigmore Street, Cavendish Square, London, W.) will be closed for cleaning from April 1st to the 30th inclusive.

W. R. (Chester).—The note on the work of the Chester Royal Infirmary for 1915 contained a slight misprint. The statement that the average per head was £73 16s. 5d. should be the average cost per bed.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION.

THE Royal National Hospital for Consumption, Ventnor, has received a further gift of £1,000 4½ per cent. war stock from Sir Ernest Cassel, to name a bed in memory of his daughter, Mrs. Ashley.

DR. MORTON.—Lejeune's method of treating burns is to inject subnitrate of bismuth into the unpunctured bullae, and afterwards to withdraw the fluid by means of the cannula still in position. An antiseptic bandage is then applied over the part, and allowed to remain for several days.

GERMAN PANEL DOCTOR.

THE London Insurance Committee have removed from the panel a doctor of German nationality, who had returned to Germany, leaving a deputy to act for him.

PES ANSERINUS (Birmingham).—We shall be glad to receive the notes of the case for publication, but preferably, we think a longer time—say three months—should be allowed to lapse in order to test the completeness of the cure.

A DOCTOR'S CENTENARIAN DAUGHTER.

MISS FANNY C. PARIS, a resident of Yarmouth, Isle of Wight, has died in her 102nd year. Her father, the late John A. Paris, was a former President of the Royal College of Physicians, London.

Vacancies.

Bootle Borough Hospital.—Junior House Surgeon. Salary £170 per annum, with board, lodging, and laundry. Applications to the Secretary, 71, Oriol Road, Bootle, Lancs.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Putney Hospital (Chester Bequest), Lower Common, Putney, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry. Applications to the Hon. Secretary, 198 Upper Richmond Road, Putney, S.W.

The Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to the Secretary.

Mater Misericordie Hospital, Dublin.—Assistant Surgeon, Assistant Physician, and Assistant to the Ophthalmic Surgeon. Applications to the Secretary of the Medical Board. (See advt.)

Royal Albert Edward Infirmary and Dispensary, Wigan.—Junior House Surgeon. Salary £150 per annum, with board, apartments, and washing. Applications to L. E. Mapei, Acting Secretary.

Appointments.

EASTON, T.H., M.D. Edin., District Medical Officer of the Penistone Union.

FITZGIBBON, MICHAEL, L.R.C.P., Assistant Resident Medical Officer (pro tem.) of the Limerick Lunatic Asylum.

GREY, H. M., M.R.C.S., L.R.C.P., Assistant Medical Officer to the South Infirmary of the St. Pancras Parish.

LIDDELL, R. M., M.B., Ch.B. Edin., Certifying Factory Surgeon for the Wolston District, co. Warwick.

MORRIS, E. G. F., L.R.C.P., M.R.C.S., District Medical Officer of the Eastry Union.

O'CALLAGHAN, J. J., L.R.C.P. and S. Edin., Medical Officer for the Glencree Dispensary District, Macroom Union.

WADSON, E. A., M.B., B.C. Cantab., Certifying Factory Surgeon for the Sedburgh District, co. Yorks.

WATSON, S. J., M.B., B.Ch., R.U.I., Certifying Factory Surgeon for the Abercrave District, co. Brecon.

WHITE, S. R., M.B., Ch.B. Oxon., Certifying Factory Surgeon for Lyndhurst District, co. Hants.

Births.

ADAMS.—On December 17th, at Wellington, New Zealand, the wife of G. Basil Doyne Adams, M.D. Oxon., of a son.

BLOOD.—On March 23rd, at 5 Brynland Avenue, Bishopston, Bristol, to Dr. and Mrs. B. N. Blood—a daughter.

GASKELL.—On March 20th, at 23 Ladbroke Grove, W., the wife of John Foster Gaskell, M.D., Capt., R.A.M.C. (T.)—a son.

GIBSON.—On March 18th, at 14 Carlisle Road, Hove, the wife of Charles W. Gibson, M.R.C.S., of a daughter (Betty Dangan).

HARE.—On March 22nd, at the Imperial Nursing Home, Cheltenham, the wife of Capt. Theodore Hare, R.A.M.C. (in France), of a son.

LAMPLOUGH.—On March 25th, at Bredon, Alverstone, the wife of Wharram H. Lamplough, M.D., temp. R.A.M.C., 31st General Hospital, Port Said, of a daughter.

MILLER.—On March 19th, at 18 Pelham Crescent, the wife of the late Captain Guy Miller, R.A.M.C., 12th Middlesex (killed in action in France on 29th December), of a son.

SHARP.—On March 26th, at Aberfoyle, Feltham Avenue, East Molesey, Surrey, the wife (née Heity, youngest daughter of the late Alban Atwood and of Mrs. Atwood, of Ballarat, Victoria, Australia), of Dr. McGregor Sharp, of 118 London Wall, E.C., of a daughter.

SKRIMPshire.—On March 18th, at Madras, India, the wife (née Logan) of Capt. F. Skrimshire, R.A.M.C., of a daughter.

Marriages.

ASPLEN—O'DONNELL.—On March 15th, at St. Stephen's Church, Cheltenham, William Reginald Ward Asplen, Lieutenant, R.A.M.C., only son of the late W. J. W. Asplen, Foxton, Cambridge, and Mrs. Asplen, Kenilworth, to Kate Nora, only daughter of the late Colonel A. C. O'Donnell, Indian Army, and Mrs. O'Donnell, Maryville, Tivoli Road, Cheltenham.

FITZGERALD—HATTON.—On March 21st, R. Desmond FitzGerald, M.B., B.Ch., Captain, Royal Army Medical Corps, son of the late R. A. FitzGerald, of Ailesbury Road, Dublin, to Winifred A. Hatton, eldest daughter of R. J. Hatton, M.I.E.E., of Lincoln House, Basil Street, S.W.

O'DONOHUE—EXHAM.—On February 24th, at the Cathedral, Plymouth, Francis Glancy O'Donohue, R.A.M.C., of Castle-rea, co. Roscommon, to Violet Maud, second daughter of the late Colonel Exham, R.A.M.C., and the late Mrs. Exham, of Plymouth.

OWEN—BOND.—On March 20th, at the Pro-Cathedral, Clifton, Ambrose W. Owen, M.D., B.S. Lond., Late Temp. Lieutenant, R.A.M.C., of Porth, Glam., to Beatrice Nina Bond, of Bridgwater, Somerset.

STEVEN—FRASER.—On March 23rd, at St. Andrew's Church, Ealing, J. Fraser Steven, M.A., B.Sc., M.B., D.S.O., Captain, R.A.M.C., second son of the late Roderick and of Mrs. Steven, 43 Lansdowne Crescent, Glasgow, to Gladys, only daughter of the late Major and Mrs. Fraser, Glenurquhart, West Ealing.

TURNER—HORNE.—On March 20th, at St. Saviour's, St. George's Square, by the Revd. Francis Boyd, Frederick Thomas Turner, Captain, R.A.M.C., son of Commander F. S. Turner, R.N., to Mary Elizabeth, daughter of the late Albert Horne.

WHITE—MACKLIN.—On March 1st, at the British Legation, Teheran, Persia, Henry White, M.R.C.S., L.R.C.P., of Yeard, to Alice Martha, eldest daughter of Mr. and Mrs. Alfred Charles Macklin, of Ingleside, Wickham Road, Brockley, Kent.

Deaths.

ATKINSON.—On March 21st, at 2 The Sweep, Clapham Common, S.W., William Atkinson, M.D., aged 62.

BURNAND.—On March 24th, at Durban, Natal, Dr. W. E. Burnand, youngest son of L. W. Burnand, M.A.

FELCE.—On March 20th, at Firlands, Burgess Hill, Sussex, Stamford Felce, M.R.C.P. Edin., M.R.C.S. Eng., late of Elgin Avenue, Paddington, in his 81st year.

HARPER.—On March 24th, at 25 Rosary Gardens, South Kensington, James Harper, M.D., Colonel, R.A.M.C. (T.), aged 58.

HEBBERT.—On March 19th, died of relapsing fever, in Mesopotamia, Robert Francis Hebbert, Captain, I.M.S., aged 33.

MURDOCH.—On March 20th, after a short illness, Dr. Mary Charlotte Murdoch, of 102 Beverley Road, Hull.

PARIS.—On March 20th, at Yarmouth, I.W., Fanny Cresswell, second daughter of the late John Ayrton Paris, M.D., F.R.S., D.C.L., President of the Royal College of Physicians, in her 102nd year.

STOCKER.—On March 19th, at Withington, Glos., James Reginald Stocker, M.B. Lond., M.R.C.S., M.R.C.P., formerly of St. Mary's Hospital, the Children's Hospital, Great Ormond Street, and Guy's Hospital, in his 72nd year.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, APRIL 5, 1916.

No. 14.

AT THE PERIPHERY.

"*Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer.*"—BEAUMARCHAIS.

The Big Reviews. MEDICAL men have, as a rule, but scant leisure for studying the contents of the larger reviews, but there are at least two of those which are now threatened with the limbo of forgotten things which deserve the attention of every thinking member of the profession. One is the comparatively new quarterly called *The Candid Review*, the other is an old and trusted friend, *The Nineteenth Century and After*. The medical article in the former deals with the past; those in the latter with the future. The contents page of "The Candid Review" contains twenty-two items, amongst which the medical eye is immediately arrested by the simple words, "Lord Lister." All the articles in this review are very well written, but this particular one has a literary flavour of a very precious quality. The story which it tells in its 8½ pages of large, clear print is one of the most typical and yet one of the most pathetic that was ever penned. The opening sentence shows where it is typical: "There is no position so dangerous as that of the heretic, in whatsoever age he lives." The element of pathos is supplied by the peculiarly gentle and Christ-like character of the heretic in this particular case.

Recognition of Genius. IN 1877 one of the leading London medical weeklies (it was not the *MEDICAL PRESS AND CIRCULAR*) spoke of Lister as having "lost himself in infatuation . . . by the glorification of an idea which is neither original nor universally accepted," and added with satisfaction that "there is less antiseptic surgery practised in the metropolitan hospitals to-day than there ever was." Unlike many pioneers, Lister fortunately lived long enough to witness the vigorous and abundant fruition of the frail plant which he had discovered, and, in the face of so much neglect, obloquy and derision, had patiently tended with such fortitude and devotion. In another passage the writer of the *Candid* article says "Genius calls to genius as deep to deep. Lorenzo de Medici recognised the genius of Michaelangelo; Paoli that of Napoleon." A further instance is supplied by Dr. Pernet in the short article which we published in our issue of March 15th. Descartes recognised Harvey. And we

know that Huxley recognised Lister. The gods have always descried and in some measure saluted one another, but the pigmies never recognise the gods. I have heard one pettifogging mediocrity describe his giant colleague as "Not only a lunatic, but a criminal lunatic." It was doubtless thus that the same breed spoke of Lister.

I MAKE no apology for transcribing the closing paragraph of the article, which in its conception is a fine tribute to one of the greatest of our profession; in its wording it is as convincing as it is restrained, and in its moral as humbling as it is uplifting:—"Lister is a very clear example of the value of a great genius to mankind. He is a clear example, because hospitals and surgery before his system and after its use provide such indisputable evidence. There is no room for argument. The most subtle-tongued lawyer could not make out any case for the pre-Listerian days. As such his life is a valuable study, for it shows the great opposition a heretic is sure to meet with from the average man, even though his truth is immediately demonstrable. It shows also that a profession itself is not the best judge of a great discovery occurring in its midst. The poet Henley, the philosophic scientist Huxley, when they saw Lister and his work in the early days, at once recognised his greatness. Lister's life shows, in brief, that peculiar technical knowledge is not the means most capable of detecting a technical genius; but that he who discovers a great man early and readily must have within himself the elements of greatness, even as Henley and Huxley had them. One great man will recognise another or other great men by an instinct that belongs to great men alone. The mass of men cannot detect genius, even though they are peculiarly trained with the peculiar knowledge that one would think should enable them to do so. Set a thief to catch a thief, and set a genius to catch a genius. One genius will catch others, and, if not other genius, will catch the highest talent. For genius knows the value of things and of men, recognises the truth from the appearance in men, and things, and consequently at all times, both in peace and war, is the most valuable asset to a nation."

The Nineteenth Century and After contains two articles of immediate interest to everyone, be he medical or lay, who takes an interest in the question which, though always one of moment, has been elevated by the war into a position of paramount importance, that of infant mortality. One of these, entitled "The Children's Food" is from the pen of Miss Constance Maud, a lady who was at one time an authority on most matters Teutonic, especially Wagnerian music. For some years past she has lived in France and has devoted her powers of observation to the study of the laws and customs of our gallant Allies, and her ready and vigorous pen to the exposition of the many lessons which we may profitably learn from them. The burden of her present song is the startling one that whereas the quality of bread is Governmentally prescribed and severely protected in France, we in this country have no Pure Food Law of any effective description.

"THE annual report of the Local Government Board for 1911
Some Horrors. and the report of the Special Departmental Committee on Food Preservatives state that among the adulterants used in the aforesaid list were found boric acid, salicylic acid, benzoic acid, sulphuric acid, formaldehyde, paraffin wax, cotton-seed oil, stearine, tallow, French chalk, ground wood, bones and shells, coal-tar dyes, copper sulphate, clay, nitre, red ochre, tannin, etc.—this list is also endless, and contains some articles which are not printable. . . . The German bakers who so largely monopolised, and under their Anglicised names still continue in many districts to monopolise this important trade in London, would be imprisoned without the option of a fine in their own dear Fatherland did they dare attempt to feed the little Germans with the 'starvation bread' they have for a generation past supplied to the children of the confiding country of their adoption."

Adulterants and Infant Mortality.

THE moral of the article, the excellence and the balance of which is somewhat marred by the fact that, following the unfortunate fashion of so many latter-day women writers, Miss Maud drags in a plea for Woman Suffrage by the heels, is that the "National Association for the Prevention of Infant Mortality and the Welfare of Infancy" fails in an important essential and will continue to fail, so long as it omits from among the planks in its platform one which calls upon the legislature to ensure that pure food and especially pure bread is as rigorously insisted upon in this country as it is in France. Certainly the indictment against the quality which is now supplied is both well drawn and convincing. Miss Maud has done a great public service in calling attention to a matter of supreme importance, which appears to have evaded the vigilance of those who are seeking for means to forestall preventable infant mortality.

A Complex Problem.

THE other article in the *Nineteenth Century and After*, though on much the same subject as that which I have just mentioned, is of a very different quality. It is entitled "Infant Mortality: a Problem of the Land," and is from the very able pen of Dr. W. A. Brend, whose interesting work on the subject of "overlying" I mentioned a

few weeks back. In the present article the writer takes a very broad view of his subject. He examines the question very carefully from every possible standpoint, and exposes the futility of dogmatizing upon any particular aspect of it. "The causes of infant mortality," he says, "are many and complex, and it is often very difficult to allocate to each its real share in the final result. Study of a large number of reports from Medical Officers of Health brings to light wide differences of opinion as to the relative effects of the principal factors responsible. Defective sanitation, overcrowding, poverty, insufficient pre-natal nutrition, artificial feeding, maternal ignorance, are each in turn claimed to be the most potent influence. The difficulty is increased by the fact that our knowledge of the pathological causes of death is in many cases still very imperfect, for such terms as 'atrophy,' 'debility,' 'marasmus,' and 'convulsions,' under which a large proportion of infant deaths are certified, are little better than cloaks for ignorance."

Health and the Land.

LATER on, on pages 623 and 624, we find the two following paragraphs: "But while there is obscurity as to the precise influences at work, the effect of rural conditions, and even of the conditions in urban areas of some size, provided they are scattered in character and broken by open spaces, stands out with astonishing clearness under all circumstances. Nor is this benign influence limited to infants. The general (standardised) death-rate in 1913 in the county boroughs of England and Wales was 15.6, while in the rural districts it was only 10.7. Among children aged one to two years the death-rate per thousand living at that age was 44 in the county boroughs, but only 20 in the rural districts. At ages two to five years the rates were 10.6 and 5.6 respectively. Practically all diseases are less fatal in rural districts, and the difference is most marked in diseases of the respiratory system and enteritis, conditions which in the aggregate account for nearly one-third of the total deaths in this country.

"The lesson to be learnt from these facts is that the surest way of improving the health of the nation is by increasing the proportion of the rural population, developing the Small Holdings Acts, and extending town-planning schemes. Although we have one of the most productive soils and favourable climates in the world, the proportion of the rural population has been steadily declining, millions of acres have gone out of cultivation, and wide areas have been changed from arable land to pasturage."

OF course, all thinking people have a Committee of long held with Sir Henry Rider Public Health. Haggard that "back to the land" was a sound as well as a sounding motto, but it has been reserved for Dr. Brend to giving convincing reasons for this faith in rural righteousness, which has become such an easy shibboleth for the opulent. The article deserves to be constituted a "reference" to a committee of public health, to be appointed for the solution of the many sanitary and hygienic problems which the conditions of the war have rendered urgent. The Prime Minister has said that committees are already at work considering various questions. It would be interesting to know if among them there is a Health Committee. The real difficulty confronting those who preach the gospel of "back to the land" is a very human one. It is simply that there is more "life" in the towns. Young people—and old people, for that matter—want to live and not to vegetate, and so long as living in healthy country districts connotes a humdrum vegetable existence, so long will people wickedly prefer the risks of unhealthiness in the towns. SINAPIS.

CURRENT TOPICS.

Health in Munition Factories.

THE Health of Munition Workers Committee has prepared for the Minister of Munitions four new Memoranda (Nos. 7—10) dealing respectively with "Industrial Fatigue and its Causes" [Cd. 8213], "Special Industrial Diseases" [Cd. 8214], "Ventilation and Lighting of Munition Factories and Workshops" [Cd. 8215], and "Sickness and Injury" [Cd. 8216].

In the first of these memoranda the Committee express the hope that the study of industrial fatigue, and the science of management based upon it, which is now being forced into notice by immediate need, may leave lasting results to benefit the industries of the country during succeeding years of peace. The memorandum proceeds:—

"Our national experience in modern industry is longer than that of any other people. It has shown clearly enough that false ideas of economic gain, blind to physiological law, must lead, as they led through the nineteenth century, to vast national loss and suffering. It is certain that unless our industrial life is to be guided in the future by the application of physiological science to the details of its management it cannot hope to maintain its position hereafter among those of its foreign rivals, who already in that respect have gained a present advantage."

Proper attention earlier in the war to the need for weekly rest would, it is stated, have prevented a large part of the diminished capacity that has been allowed to appear, and would have averted much costly and wasteful expenditure upon imperfect work. In very many cases, perhaps in almost all, in which staleness is well marked, or has even advanced to definite sickness, a single "day off," given occasionally at the right time, would have avoided much wasteful reduction of capacity, and in the worst cases the total loss of many days of work.

Dealing with special industrial diseases, the committee mention that operatives employed in the manufacture of tri-nitro-toluol have been found affected with unusual drowsiness, frontal headache, eczema, and loss of appetite. Generally the symptoms are at first slight, but if the exposure be continued the symptoms tend to become more severe, while in a few cases profound jaundice with danger to life has supervened, and even death has resulted. Tetra-chlor-ethane, a non-inflammable liquid, smells in vapour form like chloroform and is a powerful anæsthetic, leading to death. It forms an ingredient of the "dope" varnish applied to aeroplanes. An apparently effective varnish has been found which does not contain the poisonous chemical, though, unfortunately, the supply of its ingredients is at present insufficient to meet the demands.

It is noted that the introduction of new labour and of employees unaccustomed to the process concerned, particularly in conjunction with the need for speed and pressure, overtime and night work, with the consequent fatigue inevitably leads to greater risk of accident.

Good advice is proffered on many points: long hours of work, faulty positions at the bench, excessive muscular strain, too prolonged standing, machinery accidents, condition of the air supply, lighting, manufacture of explosives, and so forth, in the observance of which both operatives and foremen are invited to co-operate, event to the extent of having committees composed of workers to deal with the various matters. It is as sensible a report as it is timely.

Treatment of Cancer by S-Rays.

THE equipment of the Glasgow Royal Cancer Hospital has been added to by the installation of the Simpson Curative Rays. Two years ago Mr. Simpson, of Simpson and Oviatt, noticed that the light produced by the electric combustion of certain ores had curative effects on workmen's hands. Exhaustive trials have been made in a number of hospitals with the belief that a new bactericide and curative agency of great power has been discovered for many chronic diseases, such as asthma, catarrh, etc., and that in certain forms of cancer good results have been obtained. There is also reason to believe that the same S-rays stimulate the healing of shrapnel wounds. Mr. W. J. Chrystal, of Auchendennan, presented the apparatus, which is fitted up in one of the wards under the care of Sir George Beatson, who has done so much for the hospital.

The rays differ from the X-Rays and from radium emanations in that they are emitted from an electric arc formed between electrodes made by a special process from a mixture of the ores of certain metals, the chief being a tungstate of iron and manganese known as wolfram.

Cancer, being the terrible malady that it is—baffling all hitherto tried forms of treatment, scientific, mainly quasi-scientific, and otherwise—it is wise to try any means, likely or not. But it would be just as wise to have a central authority to record the results of these experiments to avoid their repetition with disappointed hopes. Here is a splendid chance for the British Medical Association, that can build a committee as the Saltmarket barber shaves his customers—while you wait. But we would advise our readers and their friends not to build on the success of this treatment yet. We have seen so many of them—"our little systems have their day, they have their day and cease to be." It is an unhappy peculiarity of our profession to be prone to go a-worshipping after strange gods: when we discover a truth we are very apt to think it is "the truth, the whole truth, and nothing but the truth." Already that tendency has shown itself: already the S-rays are vaunted as curing, or helping to cure, workmen's hands of pathological conditions, shrapnel wounds, asthma, catarrh, and some kinds of cancer. "Methinks he protests too much." But, by all means, let it be fully and freely tried. Serum, radium, bacteriological, and the other fancy treatments of the gang of original researchers have all been hitherto so barren that experiment of any kind is quite as likely to succeed in this way as in the more priggish forms already fully tried.

Hay-Fever.

THE time will soon be here when those of us who weep with the coming of June must consider to what remedy they will have resort this year. If the contemplation of the miseries of others be of any comfort, we may console ourselves with the knowledge that hay fever is more prevalent by far in other climates than ours, and exacts a longer period of subjection from its victims. In parts of the United States it has been estimated that not less than 1 per cent. of the total population is subject to the distressing malady, and strenuous efforts to discover and combat its origin are being made by the American Hay Fever Prevention Association. The hay fever of spring which flourishes in European countries is found to be caused chiefly by the pollen of the flowering grasses. The autumnal type, most prevalent in America, has proved due to the pollen of certain flowering weeds, principally the rag weed. The scientists engaged on this research kept two points well in

mind—first, that the flower at fault must ripen at a time corresponding to the onset of the malady, and, secondly, that the pollen must be light enough and borne in sufficient quantity to be carried long distances by the wind. In the ragweed both of these conditions are fulfilled, and prophylaxis here takes the form of the systematic eradication of the obnoxious weed. In this country we have no such simple means of dealing with the trouble, and until some specific remedy be found we must just put up with the inconvenience of living on a grass-grown isle. Treatment is still experimental. Immunisation by pollen extracts and by serum of horses which have been immunised to pollen, has been tried with varying results; bacterial vaccines, too, have had their chance. In a few cases a combination of these two treatments has been of use. There is a third therapeutic measure which deserves further trial—the administration of calcium chloride. Wilson, of Detroit, reports a series of twenty-six cases treated with this salt in doses of 3 gm. daily, which includes some instances of remarkable cure. Scepticism as to results is unavoidable where the number of infallible remedies reported have been legion, but the subject is one well worth further investigation.

Infantile Mortality in Dundee.

DR. TEMPLEMAN, Medical Officer of Health for Dundee, has issued his annual report on the health of the city, and it is a very astounding report, too. The population of the city was estimated at the middle of 1915 as 177,300. Births registered for the year 3,927, a birth-rate of 22.15 per 1,000; of deaths 3,755, a death-rate of 21.18 per 1,000. The number of infants under one year who died was 821, giving an infantile death-rate of 209 per 1,000 births.

The general death-rate for 1914 was 16.87, as compared with 21.18 in 1915. This great difference is accounted for by, in part, the abnormal death-rate among the infants as noted above [this was due to virulent epidemics of whooping-cough and measles], and in part also by increase of death-rate at the later periods of life, which, the doctors say, "may be due to a diminished recuperative power owing to the severe strain which the nation has suffered owing to the war." The rate of illegitimacy in Dundee fell in 1915. Dare we say that the war-baby has not materialised to any great extent yet anywhere in the United Kingdom?

Regarding the infant death-rate, Dr. Templeman refers to the carelessness and ignorance of mothers in allowing their babies to be in an infected house, as they think it is better for children to get these ailments, like whooping-cough and measles, soon over and done with—like baptism and vaccination. He also speaks highly of the efforts of baby-clinics, which he says are doing splendid work and should be extended. He brings out clearly in the case of diarrhoea what the late Dr. J. B. Russell did for Glasgow in the incidence of tuberculous disease, the effect of bad housing. "There were 132 deaths of infants from diarrhoeal diseases. Of these 39 occurred in houses of one room, 72 in houses of two rooms, 15 in houses of three rooms, 2 in houses of four rooms, and none in houses of a larger size."

But it would seem that the resisting power of these children is of a low grade: they are mainly hand-fed, and the means for keeping milk pure are woefully inadequate. More, no artificial food for babies at all approaches the breast-milk of the mothers. Unfortunately, from custom, or social conditions generally, an exceptional number of mothers in Dundee are breadwinners, working in mills and factories, and so their babies (pre-natally ill-nourished for these reasons) have to be artificially

fed. This seems to be the crux of the question: mothers should nurse their own children—themselves.

The Drug Habit.

VIEWS recently enunciated by eminent authorities upon the subjects of morphinism and allied addictions are worthy of the closest attention. Bishop, of New York, as a result of observations made by him at the Bellevue Hospital, coupled with information obtained in the consulting room, has come to some striking and suggestive conclusions. It is his opinion that to regard the majority of morphinists as wilful yielders to morbid temperament is fundamentally an error. They are handicapped by an abnormal or deficient physiology—of congenital origin—which causes them to experience exceptional difficulties in life from day to day. He states that in very many cases chance has brought to their knowledge the means by which, initially at all events, they attain the relatively effortless level of their normal fellows. Moreover, in many instances, the subject, by exercise of insight, continues over prolonged intervals, to manipulate doses which just keep him up to par, without exciting any suspicion whatever, or causing grossly untoward results. This if his minus quantity be small and readily satisfied. If the physical equation be difficult, however, and ingravescent, we have the hitherto obstinate degenerate—the morphomaniac. Treatment, consequently, must not be symptomatic *i.e.*, not merely directed against the phenomena of morphinism *per se*—but must seek to remove the physical and physiological aberrations, to compensate for which the drug was first taken. It is conceivable that the principle might be extended eventually to include other addictions. The well-known clinical fact of alcoholism ensuing upon the climacteric in subjects hitherto of the greatest temperance—not to stretch the matter further—certainly lends support to the views thus stated.

Paper Money as an Infectant.

A SCOTCH correspondent writes:—Certain subjects recur in newspapers as regularly as the seasons, and the above is one of them. Others are the big gooseberry, the potato like the face of — (whoever is our pet devil at the time), the three-winged gull, the hexaped calf, etc. It is time now for someone to "get off" about the daffodil "that comes before the swallow dares," etc., to be followed by "Oh! to be in England now that April's —," etc. Frankly, that last quotation hits us northerners hard: we are sick here of the killing east wind; we have had it so long. But paper money was our set-off. The greatest danger about paper money that we have encountered is its abounding scarcity. That did not seem to be what the *Manchester Guardian's* representative felt. (I wonder if that paper wants a medical expert.) It was the dirt of them: the pathogenic *materies morbi* on their crinkly, greasy surfaces. And the smell. It is difficult in crowded communities to trace where infection comes from; but we do not remember a case of disease traced to a bank-note. To anyone who fears infection from this source, he might burn the notes, or if that is too radical a method of treatment, he could send them to Scotland and we would take care of them.

Medical Vocation.

A CONTEMPORARY journal, in discussing the reasons which impel most young men to select the profession of medicine, instances chance, choice and destiny, as the three probable predominant factors. The last and, to some extent, the first, are, we

believe, open to question. The power of choice is more evident, and may be regarded as two-fold in aspect—viz., selection by the individual himself upon more or less deliberation, and selection for him by those immediately interested in his prospective career. This latter course, in many cases necessary owing to youthful lack of initiative, is definite in wisdom. We do not imply that the selection of medicine as a profession is arbitrary and overbearing upon the part of seniors. It is more a matter of continuous suggestion, in which the subject acquiesces through sheer apathy. Many a man, born into therapeutics in this fashion, comes to act in a relatively admirable capacity eventually; but never works into the keen mental edge of him who has looked around and selected for himself. The attempt should be made to induce the dormant enthusiasm in the young, and conform to it as far as possible in the selection of a career. It is remarkable that in the face of much mental indifference, or even of distaste, that men should behave so creditably; but it is uneconomic, and a waste of time, that so many should be able to cry with Rosetti:

"Who shall say what is said in me

With all that I might have been dead in me?"

Localised Tetanus.

DR. MONOD recently brought this subject before the Paris Academy of Medicine and showed a case of tetanus localised to the upper limb, with complete recovery. He stated that these cases are perhaps more frequent than is commonly imagined. The "secondary traumatic muscular spasms," described long ago by Follin, belonged most probably to the same variety of cases, only Follin considered that they presented the same gravity as true tetanus. The treatment applied by Dr. Monod consisted in high doses of chloral and subcutaneous injections of sulphate of magnesia. He used the following solution:—

Sulphate of magnesia, with 7 parts of water, 250 grammes,
Distilled water, 1,000 c.c.,
of which he injected each time 10 c.c. The patient received 32 injections in 13 days, and the author particularly noted the marked calming action of these injections.

"The College of Nursing" and State Registration of Nurses.

THE conferences between Mr. Arthur Stanley and the other promoters of the College of Nursing on the one hand, and the supporters of State registration of nurses on the other, have come to a conclusion. We cannot regret that this is so, and that the issue is now knit, since the differences between the two schemes are fundamental and essential. Mr. Stanley's parlour was temptingly furnished, and his invitations to enter it were blandishing and polite, but fortunately the prey has not been caught. The promoters of State registration have now to set themselves to oppose Mr. Stanley's scheme by every means in their power. If they do not succeed, we may give up all hope of State registration, or, on the other hand, we may have to accept a one-sided scheme which will be worse than none. Mr. Stanley proposes to institute a college of nursing, which may or may not proceed in the future to demand State registration. But as Dr. McGregor Robertson pointed out the other day, the question is: Should they have State registration of nurses or State registration of members of the College? Moreover, Mr. Stanley proposes to issue certificates and enrol not only trained nurses, but voluntary aiders, and to others concerned in "all branches of women's work connected with hospitals" other than

the practice of medicine. We may expect a hierarchy of certificated persons ranging from the wardmaids and laundresses to the matrons! It is with some interest we note that the council nominated by Mr. Stanley to govern the College of Nursing contains no representative of Ireland and only one of Scotland.

The Midwife.

THE midwife, like the class for whom she caters, is always with us. From Philadelphia we learn that fully 40 per cent. of confinements in that area find successful, or unsuccessful, issue in their hands. This is to be deplored, inasmuch as the female obstetrical freelance is largely represented there, and no system of supervision appears to have been yet inaugurated. The English system is criticised as being only partially successful. Reference is made to St. Louis, where a school for midwives has been instituted, which will, however, require an admission standard above the mental level of an average midwife. Moreover, the melancholy conclusion is eventually arrived at that, no matter how a midwife be licensed or supervised, she never attains the mental or manual efficiency of a practising doctor. It is singular that so essentially a process as child-bearing should fail in the hands of women. Hence, concludes our Philadelphian authority, let them be eliminated as soon as possible.

PERSONAL.

MR. MORGAN I. FINUCANE, M.R.C.S., L.R.C.P., Barrister-at-law, has been appointed J.P. for the County of London.

DR. E. C. THOMPSON, of Omagh, formerly member of Parliament for Monaghan, has been appointed a Deputy-Lieutenant for the county of Tyrone.

DR. MALCOLM E. THOMPSON, Boston, Lincs, was at Boston County Court awarded £40 damages for injuries sustained by a collision between his bicycle and a motor car.

SIR ALFRED PEARCE GOULD, F.R.C.S., has been nominated by Lord Reading a member of the governing body of Charterhouse School. The vacancy was caused by the death of Lord Alverstone.

THE King of Serbia has conferred the Third Class of the Order of St. Sava upon Lieutenant-Colonel H. E. M. Douglas, V.C., C.M.G., D.S.O., R.A.M.C., Deputy Assistant Director of Medical Services.

THE KING has been pleased, by the advice of the Privy Council, to nominate Sir Francis Henry Champneys, Bt., M.D., F.R.C.P., M.R.C.S., to be, for a further term of five years, a member of the General Council of Medical Education and Registration of the United Kingdom.

AT Keighley much satisfaction is felt at the news of the safety of Dr. Jno. Parton Berry, son of Dr. Jno. Bright Berry, of Keighley. The younger man was senior surgeon on the "Alcantara" when she fought the German raider. Dr. J. P. Berry had four years' surgical experience with the Fleet, and resigned some time before the war, but was called up at the outbreak of hostilities.

DR. W. J. A. ERSKINE, who since 1900 has been the deputy medical superintendent at the Nottingham City Asylum, has been appointed medical superintendent of the Isle of Wight Asylum at Newport. Dr. Erskine, who is very popular with the staff at the Nottingham institution, has had great success in training nurses and attendants for the Medico-Psychological examinations. He has written on a number of subjects connected with lunacy.

FRENCH CLINICAL LECTURE

ON

TREATMENT OF ACUTE ARTICULAR RHEUMATISM WITH
INTRAVENOUS INJECTIONS OF COLLOIDAL GOLD.

By M. H. GRENET.

Medecin des Hopitaux, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

PART II.

Technique and Mode of Application.—Injections of colloidal gold may be employed to the exclusion of every other kind of treatment; at the utmost we merely have recourse in addition to wrapping up of the most painful of the affected joints in wadding, or some local applications of methyl salicylate. We have employed blue colloidal gold, obtained by the chemical process, and containing 0.25 milligramme of the metal to 1 c.c. This is the preparation known commercially as *collobiase d'or*.*

The administration of the injection should be *intravenous*; intramuscular injections have but little effect.

As regards *dosage*, we advise the physician not to exceed, for the first time, 1 or 1.5 c.c.; especially if the temperature is high, and the patient greatly agitated; as the intensity of the reaction cannot fail to be accompanied with danger. The subsequent injections may then range in amount from 1.5 to 2 c.c.

A single injection suffices in some cases; but in the greater number it will be necessary to administer two, three, or even four. The successive injections should be given after intervals of 24 or 48 hours. If the temperature proceeds to subside regularly after an injection, we may await developments; sometimes definitive apyrexia will be established in the course of three or four days, without repeating the injection; but we should always hold ourselves in readiness to repeat the injection on the slightest indication of reappearance of the fever or articular pains.

When the patient has become completely apyretic, and commences to walk, we must be prepared to deal with the weakness and pains in perhaps one or two articulations. At the commencement of one of our investigations, we were of the opinion that collobiase was then of no further use; so that we proceeded to the administration of aspirin, and submitted the patient to the application of various external medications (sulphur baths, local heating, etc.). But we are now convinced that the injections of gold are useful in this stage also, and that a puncture made every three or four days leads to a fairly rapid absorption of the exudate—which is a specially prominent feature in cases occurring after the age of 35.

If the patient has presented cardiac symptoms at the commencement of the attack, it seems to us to be beneficial to renew the injections, even after the fever has completely subsided; one or two punctures, made in the apyretic period, have indeed, in some of our cases, secured the complete return of the heart to its normal state.

In a case of subacute rheumatism, the action of colloidal gold is, as a general rule, less rapid and less complete; it will be found necessary to administer at least four or five injections, at intervals of some days. But we have, nevertheless, obtained results which seem to us to be still superior to those yielded by the use of salicylates in those always troublesome

cases; and, more especially so, as we have always been able to obviate the occurrence of endocarditis.

The course of treatment of rheumatism with colloidal gold is sometimes completed by having recourse to articular puncture. In most cases of the acute type, the hydrarthrosis rapidly disappears under the influence of the injections; but it sometimes persists in one or both knees, provokes the continuation of pain, and undergoes absorption but tardily. If the effusion is copious in quantity, it will be necessary to evacuate it after the subsidence of the fever; in the majority of cases it will not recur; and we then do not hesitate to make the patient leave bed two days after the puncture. When the fluid withdrawn from a joint presents a marked polynuclear reaction, we may fear a relapse; but if the lymphocytosis is approximately pure (and that is what we most frequently meet with some days after the treatment), the probability of relapse is but slight; then the effusion behaves very much like a foreign body, which it is accordingly desirable to remove. On this account we always should, after the subsidence of the fever, puncture any articulations which still remain tense. By this means we hasten the completion of the cure, and also obviate in great measure the appearance of consecutive muscular atrophy.

ACTION OF COLLOIDAL GOLD.

Such are the rules which we believe appropriate for the treatment of acute articular rheumatism. Let us now see how the colloidal gold acts.

(1) *Stage of Reaction.*—Fifteen or twenty minutes after the injection, a rigor of great intensity develops and lasts for a quarter of an hour; rapid elevation of temperature, which often rises above 40° (104° F.); abundant sweats. This reaction attains its maximum at the end of one to two hours; it is nearly over at the end of three hours.

(2) *Effect on the Pain.*—The intravenous injection of colloidal gold exercises a very clearly defined analgesic action. The patients usually experience relief some hours after the puncture; they begin to move their limbs, which had previously been completely rigid. Those who had previously been submitted to the salicylate treatment are always the first to affirm the superiority of that with gold. One of our patients, indeed, who was affected with a grave type of rheumatism, and in whose case the fever persisted in spite of three weeks of treatment, was quite relieved from suffering for some days after the puncture had been resorted to; the salicylate treatment had neither relieved the articular pain nor lowered the temperature; and this young man actually felt well, despite the persistence of the fever; and, of his own accord, asked for a repetition of the injection when the pain recurred.

(3) *Effect on the Temperature.*—After one or two—sometimes three—injections, repeated at intervals of three days, the fever subsides, sometimes brusquely, sometimes in course of three or four days. Such is the general rule; but we sometimes meet with rebellious cases, in which the injections have to be repeated up to the number of five or six. Such are, however, but the exception; and it appears, too,

* We are indebted for our own ampullæ of collobiase to obliging kindness of the firm Boulanger, Dausse et Cie.

that the salicylate treatment gives no better result in those cases.

(4) *Action on the Articular Effusion.*—As a rule the effusions undergo rapid absorption; when they persist, puncture should be resorted to, as we have already said.

(5) *Action on the Complications.*—One of the most remarkable results of the gold treatment is the suppression of the cardiac complications. The presentation of some figures in this connection will give precision to our ideas.

We have treated 54 cases of rheumatism with salicylates. In that series we met with 13 examples of cardiopathy, of which 6 were cured (4 cases of endocarditis, 2 of pericarditis). There were 7 cases of organic, definitive cardiac lesion (1 double lesion of the mitral valve, 5 of mitral insufficiency, 1 of apparently pure mitral narrowing).

We have in turn submitted 84 patients to the colloidal gold treatment. In 8 of those cases, it was adopted only late in the course of the disease; and of this number 3 had already developed a valvular lesion, which was fully established at the time of the first injection. Thus there remained a series of 76 patients who received timely treatment with the collobiase; one of these died during the stage of reaction (Obs. XIII.). Among the others, 5 presented, at the time of their entrance into hospital, well defined symptoms of endocarditis in course of evolution. Those were all completely cured in some days. Not one of our cases has ultimately retained the smallest sign of cardiopathy.

Thus, with the salicylate treatment we had 7 cases of definitive valvular lesion remaining among our 54 cases; with the colloidal gold, we had among the series of 76 cases who received timely treatment 1 case of rapidly occurring death, and one of definite cardiopathy.

In one of our cases—a patient who had previously suffered from a number of attacks, and presented a subacute form of the disease—we have seen rheumatic iritis develop after he had already received several injections and appeared to be fully convalescent. We proceeded to carry out local treatment (hot compresses, atropine collyrium) and administered an injection of 2 cc. of collobiase. The improvement was rapid at first; then, as a slight relapse occurred, a second injection was given, and the cure was complete in three days. We have thus received the impression that the colloidal gold in this case distinctly favoured the action of the local treatment.

Two of the cases that we had treated with gold presented spinal symptoms (rigidity of nucha, Kernig's sign); but these yielded at once to lumbar puncture (the cephalo-rachidian fluid was normal).

(6) *Action on the General Course of the Disease.*—The treatment with colloidal gold produces a notable abridgment of the course of the disease, inasmuch as it enables the patient to leave bed sooner, since a grave relapse need not be feared. The fever often subsides in three or four days. But even when the antithermal action has not been so rapidly manifested, and the temperature has not subsided before the end of five or six days, the very important fact remains that we can begin to mobilise the patient very soon—after two days of apyrexia. In this matter we proceed in the following way. During the course of the crisis the patient is retained in bed, and is nourished with milk and eggs. The temperature having subsided, after one day of apyrexia we allow the use of legumes; on the second day, the patient sits up and is allowed to walk a few steps; on the third day (when there is no albuminuria) the alimentation is made nearly quite normal, and we allow the patient to walk about a little in the bedroom. A good many

of our patients even make a little promenade outside, and go downstairs at the end of five or six days; a great number enter on the stage of convalescence fifteen days after the commencement of the attack. There has never been a case of prolonged relapse; sometimes, indeed, after leaving bed a little too hastily, a slight elevation of temperature followed, accompanied with some swelling of the knees; but three or four days more in bed and a new injection always proved sufficient to stragulate any such attempt at relapse. Now, everybody knows how necessary it is to be cautious in mobilising rheumatic patients who have been treated with salicylates; also, how frequently, in spite of all such prudence, relapses—many of grave character, too—are prone to occur. In this respect, the treatment with colloidal gold gives very remarkable results indeed.

(7) *Contra-indications of this Treatment.*—Colloidal gold is an active medicament, which requires to be manipulated with a certain degree of caution; of this fact our own fatal case may be taken as proof. When the temperature is very high, and the patient is greatly agitated, we should administer but a feeble dose; we are even of the opinion that, having regard to the intense, even although transitory, congestive phenomena which are produced by the injection, we should abstain from the administration in cases of hyperpyrexia or cerebral disturbance. Such conditions seem, indeed, to us to form the only contra-indications to this treatment. On the other hand, the occurrence of endocarditis at the outset calls for an immediate use of this remedy; when asystolic phenomena are present, the dose administered should be a small one (0.5 to 1 cc.) it is also desirable in some cases to have recourse to a preliminary injection of spartein or of camphorated oil, from the fact that colloidal gold produces an accentuated cardiac erethism, although but of transitory duration.

COMPARISON WITH OTHER METHODS OF TREATMENT OF RHEUMATISM.

We have already, in the course of the present communication, indicated our reasons for concluding that the treatment of rheumatism with colloidal gold is superior to that with salicylates, so that we need not discuss the question again. We have also communicated our early results to the medical meetings of the physicians attached to the sixth army corps. Almost at the same date, MM. Loeper and Varham published the successes which they had obtained with injections of colloidal sulphur. While admitting that the number of their published observations is but small, it appears to us that we have secured more rapid and constant results from our own use of gold. We have brought two points into prominent relief: the rapidity of convalescence and the suppression of cardiac complications; so that, far from contra-indicating the use of colloidal gold, a case of endocarditis in course of evolution actually demands it. We do not as yet definitely know whether the colloidal sulphur will have the same preventive action in presence of the development of cardiac complications; but we are already satisfied that every appearance testifies to the fact of its having been established in the case of gold.

Besides, it is very possible indeed that the use of other colloidal metals may be followed by a corresponding degree of success. We have tried gold, and have unquestionably found it a superior remedy to any that we had previously employed, and we have proposed to ourselves to carry out corresponding clinical researches with colloidal silver (electragol, which we employed in one case, gave us no result). It is certain that the colloidal state possesses as great importance in the success of the

therapeutic procedure as the nature of the metallic element itself; we are also equally sure that in the matter of colloidal metals the mode of preparation plays a *role* of considerable importance, and this has been our reason for indicating specially the clinical fact that our own patients have been treated with the preparation known as collobiase of gold.

ACTION OF COLLOIDAL GOLD IN THE VARIOUS SO-CALLED RHEUMATIC STATES.

The results which we have hitherto discussed were all obtained in the treatment of purely acute articular rheumatism, and in the subacute forms of the same disease. But we have also employed colloidal gold in the treatment of two cases of *seric* rheumatism (consecutive to injection of anti-tetanic serum), in two cases of blennorrhagic rheumatism, in one case of infectious mono-articular rheumatism of undetermined nature, in one case of rheumatoid purpura, and in one case of arthropathy in a tuberculous patient who was suffering from dysenteriform diarrhœa. In every one of those patients, the injection of gold produced an attenuation of the pain, but did not appear either to abridge or otherwise modify the normal evolution of the disease; the cases of blennorrhagic rheumatism recovered slowly; the infective mono-articular rheumatism ended in a partial ankylosis of the knee-joint; the purpura yielded only to prolonged rest in bed; the arthralgias of the tuberculous patient recurred after a partial subsidence of some days. Accordingly, the collobiase of gold is above all things a remedy of pure rheumatism. It may prove useful in the treatment of pseudo-rheumatic conditions, but only by functioning as an effective analgesic. And by acting in the same way, as an analgesic agent, it has give us satisfactory results as a remedy in two cases of rebellious sciatica.

CONCLUSIONS.

Intravenous injections of collobiase of gold, when administered in cases of acute articular rheumatism, produce the following effects:—An analgesic action, which is constant; a fall of temperature which is often quite abrupt (this result is very frequent, but is not quite constant); abbreviation of the duration of the attack, not only as regards a rapid subsidence of the fever, but of otherwise special importance, because, after the lapse of two or three days of apyrexia, we may commence to get the patient out of bed without fear of producing a serious relapse; considerable abbreviation of the period of convalescence; suppression of rheumatic endocarditis. The favourable results of injection of collobiase are specially manifested in the purely acute cases; but they are also displayed in the subacute, although in somewhat less degree.

ORIGINAL PAPERS.

HEXAMINE AS A URINARY ANTISEPTIC.

By J. W. THOMSON WALKER, M.B., F.R.C.S.
Surgeon to the King George Hospital and to N.W. London
and Hampstead General Hospital; Assistant Surgeon
to St. Peter's Hospital for Stone.

A URINARY antiseptic may be defined as a drug administered by mouth, with the object of producing an antiseptic action in the urine. Such a drug acts under great disadvantages as compared with antiseptics used in surgical work. The urinary antiseptic passes through two selective organs, the intestines and the kidneys, and for a time circulates in a powerful oxidising agent—the blood—before finally arriving at the seat of bacterial growth in a solution of uncertain concentration.

It is not conceivable that a powerful antiseptic such as is used in antiseptic surgery can be passed through the delicate cellular substance of these organs, and mix with the blood in sufficient concentration to act as an antiseptic, without at the same time causing serious damage to the intestines and kidneys and acting upon the constituents of the blood.

Antiseptics act by their affinity for the protein of the bacteria. In the diseased urinary tract the bacteria are suspended in a protein-rich medium, and the bactericidal substances combine more readily with the protein in the urine than with that of the bacteria. The urinary antiseptic is thus handicapped in its action by a protective covering around the bacteria.

By far the most important urinary antiseptic in use at the present time is hexa-methylene-tetramine. This was originally known under the proprietary name of Urotropin, and is now manufactured in this country under the name of Hexamine. This drug more nearly approaches the ideal urinary antiseptic than any other, for it contains in an innocuous form, which passes unchanged through the intestines and kidneys, a powerful antiseptic which is liberated in the urine.

Hexamine is a condensation product of ammonia and formaldehyde. An aqueous solution (10 per cent), to which a little ammonia has been added to prevent splitting off of formaldehyde, has no antiseptic action in bacterial cultures. The combination does not possess a high degree of stability. Tablets of hexamine which have been exposed to the air for some months show deliquescence, and on dissolving in water the reaction is acid, and free formaldehyde is present in abundance.

Hexamine is frequently prescribed with acid sodium phosphate, and I shall, later, refer to the significance of this combination. For the present I am only concerned with the effect upon the constitution of the drug. In a very short time the solution is found to contain free formaldehyde in large amount. The same is found in all combinations of acids with hexamine, whether in the form of dry, compressed tablets or as solution. The importance of this is obvious.

Hexamine owes its value as a urinary antiseptic to the fact that the formaldehyde which it contains is embodied in a form which is readily absorbed without damage to the intestines, which causes no change in the blood, and has no deleterious effect on the kidney during excretion. It is only at the seat of infection, namely, the urinary tract, that formaldehyde should be liberated and exercise its effects.

In clinical work it is recognised that Hexamine acts best when given in a large draught of water, between meals, and the complaint is sometimes made by patients who are taking the drug after meals that it gives them indigestion. The "indigestion" is probably due to the acid gastric juice acting on the Hexamine and liberating formaldehyde in the stomach. This is obviated by giving Hexamine between meals, with sufficient fluid to dilute any gastric juice that may be present. In order further to obviate the splitting effect of the gastric juice I have had Hexamine tablets coated with keratin, and these tablets (Messrs. Burroughs, Wellcome and Co.) may be used where such splitting in the stomach is suspected.

Hexamine is rapidly absorbed from the intestine, without causing irritation, even in large doses. It circulates in the blood as Hexamine, although it is said that a very small amount of formaldehyde is split off, and can be detected by the more delicate formaldehyde tests. The greater part of the drug is excreted by the kidneys, but it has also been

found in the bile and pancreatic secretion, in the sputum, and in the secretion of the nasal sinuses, and middle ear. It can be detected in the cerebrospinal fluid obtained by lumbar puncture, and in the synovial fluid. In regard to the antiseptic value of Hexamine, in these alkaline media, I must confess I have very considerable doubt.

In the acid urine in which most of the drug is excreted, the Hexamine is split, and formaldehyde is given off; and to this its antiseptic power is entirely due.

It is now possible to detect by simple tests the presence of free formaldehyde in the urine, and to differentiate this from formaldehyde in combination as Hexamine. The following are the two tests most suitable for clinical use:—

1.—Phloroglucin test. The following solutions are used:—(a) Aqueous solution of phloroglucin (1 per cent.); (b) solution of caustic soda (30 per cent.). A few drops of phloroglucin solution are added to the urine in a test tube, and then 5 drops of caustic soda solution. A bright cherry red colour appears if formaldehyde is present, but no colour if there is only Hexamine in the urine. The test will show the presence of formaldehyde in a dilution of 1 in 50,000 in the urine.

2.—Burnam's modification of Rimini's test. The following three solutions are used:—(a) Phenylhydrazine, hydrochloride, 0.5 per cent.; (b) sodium nitroprusside, 5 per cent.; (c) sodium hydrate saturated solution. Three drops of each of the first two solutions are added to the urine, and a few drops of the sodium hydrate solution poured along the side of the test tube. The urine and the sodium hydrate should be warmed to slightly above the body temperature.

If formaldehyde is present, a dark greenish-black cloud passes down through the urine. This rapidly changes to green, and fades through bright green to orange and pale yellow.

This test will detect formaldehyde in urine, in a dilution of 1 in 150,000, but does not show the reaction with Hexamine. According to Burnam, there is an intense dark blue colour, changing to green, in solution of 1 in 20,000 or stronger, and in solution of less strength the first colour is an intense green.

If these tests for formaldehyde are negative, a fresh sample of urine should be boiled, after the addition of a few drops of sulphuric acid. The test is then applied, and if the formaldehyde reaction is now present, the urine has contained urotropin.

The clinical importance of these tests is great. As will be seen subsequently, there are many factors which modify the excretion of Hexamine, and the liberation from it of formaldehyde, and which therefore hamper its antiseptic action. With a simple, easily applied test, the presence or absence of the formaldehyde in the urine can be checked, and the cause for its non-appearance searched for and remedied. Of the two tests, I prefer the Burnam-Rimini. The colour is very striking, and there is no difficulty in deciding as to a positive or negative result. A disadvantage for clinical work is that the solution must be fresh in order to give reliable results. In order to obviate this, Messrs. J. Bell and Croyden supply the solution in ampoules, each containing the proper amount of the drug.

I shall now refer briefly to the excretion of Hexamine in a normal individual. After a dose of 10 or 15 grains of Hexamine, the drug, or formaldehyde can be detected in the urine in about an hour, but it is frequently delayed longer than this, two or even three hours being not unusual in my experience. The excretion is at its maximum during a period of from 4 to 8 hours after administration. After about 12 hours the excretion is still going on in small quantities. I have detected formaldehyde

in the urine 17 and even 22½ hours after a single dose of 15 grains of Hexamine. It would thus be possible by taking two doses of 15 grains in 24 hours, and passing water as seldom as possible, to keep the urine in the bladder, continuously mixed with a strong solution of formaldehyde.

In diseases of the bladder in which frequent micturition is a symptom, the period during which the bladder is under the influence of formaldehyde is reduced to 6 or 8 hours, the time during which the drug is being excreted in quantity by the kidneys. In such cases small doses frequently repeated (7 grains every 4 hours) will be more effective in giving a continuous antiseptic action.

The commonly prescribed dose of Hexamine is 5 or 10 grains, taken three times daily. An increase in the dose to 15 or 20 grains, three times daily, will be followed by an increased output of formaldehyde in the urine. It frequently happens that no formaldehyde is produced in the urine when the patient is taking 5 or 10 grains, but there is abundance of formaldehyde with the doses of 15 or 20 grains, or when the formaldehyde reaction is feeble with the smaller doses, it becomes powerful when the dose is doubled or trebled.

According to a rough estimate of Burnam, the administration of 10 grains of Hexamine thrice daily will give a solution of about 1 in 5,000 of formaldehyde in the urine. This may, conditions being favourable, suffice to destroy an infection of the urinary tract. On the other hand, the infection may persist in spite of the continuous antiseptic action.

There is a limit to the increase in dosage, which in some individuals is very quickly reached. Hexamine itself is non-toxic, but the liberation of a high percentage of formaldehyde in the urine gives rise to irritation of the urinary tract. Irritability of the bladder, frequent micturition, and, eventually, strangury may occur. Hæmaturia has been recorded in a fairly large number of cases. These symptoms have been known to follow small doses (2½ grains) in certain individuals, but this idiosyncrasy is fortunately uncommon. Many patients can take 15 or even 20 grains, three times daily, without irritation. On the whole, I am inclined to prescribe larger doses than is customary, and this is especially the case in dealing with an infection of long standing. It is better, I think, to produce a powerful antiseptic action, and do it for a short time, than to be content with a feeble action spread over a long time. The symptoms of an overdose of Hexamine are, after all, not of a very alarming or of a permanent character, and can be quickly controlled by ceasing the administration of the drug and giving an alkaline mixture. Doses of 20 or 25 grains repeated every four or six hours, for 24 or 48 hours, may suffice to cut short an infection which will drag on for weeks or months with the smaller doses. It is a wise precaution before giving these larger doses to ascertain by smaller doses if the patient has any idiosyncrasy in regard to Hexamine.

CERTAIN CONDITIONS WHICH MODIFY THE ACTION OF HEXAMINE.

1. Variation in the reaction of the urine.

(a) Drugs which affect the reaction of the urine. It is necessary, as a preliminary to the consideration of the effect of alkalis and acids upon the action of Hexamine, to refer to the drugs which act on the reaction of the urine, and the influence upon bacterial growth of variations in the reaction of the urine.

The normal acidity of the urine is due to the presence of acid sodium phosphate, and the acidity

varies in different individuals, and at different periods and times of the day, under influences which are well recognised and need not detain us here.

There is seldom any difficulty in reducing the acidity of the urine and giving it a moderately alkaline reaction. The drugs which are commonly used for this purpose are potassium citrate and acetate, and sodium bicarbonate. The latter drug is, in my experience, the most powerful.

It is a much more difficult matter to turn an alkaline urine acid. Mineral acids (hydrochloric, sulphuric, phosphoric) have an extremely slight action. Organic acids (tartaric, acetic, citric and lactic) have a slight but distinct action in increasing the acidity of the urine. Benzoic and boric acids have no influence on the reaction of the urine.

Dr. Robert Hutchison recommended the administration of sodium acid phosphate with the view of increasing the acidity of the urine, and this drug has proved of great value. Ammonium benzoate may render a strongly alkaline ammoniacal urine acid, where other drugs have completely failed.

In practice there are only two drugs which will render a really alkaline urine acid. These are acid sodium phosphate and ammonium benzoate. The former may be given in doses of 30 grains thrice daily, and, if necessary, increased to two or four drachms thrice daily. In the larger doses it may cause diarrhoea. Ammonium benzoate is given in doses of 15 or 20 grains thrice daily.

(b) The influence of alkalis and acids on the action of Hexamine.

It has long been recognised that the action of Hexamine is more powerful in an acid than in an alkaline urine. With the recognition that Hexamine acted only by the production of formaldehyde, the question of its efficiency has now turned upon the splitting of Hexamine in an alkaline and in an acid urine. A good deal of discussion has waged around this point, and it was at one time stated that formaldehyde was produced as readily in an alkaline as in an acid medium. The chief difficulty has been the lack of an accurate test which will distinguish free formaldehyde from formaldehyde combined as Hexamine.

The two tests that have already been described clearly distinguish between free and combined formaldehyde, and permit of an accurate statement in regard to the effects of an alkaline and an acid urine, on the dissociation of Hexamine being made.

There are two aspects of the question to be considered. The urine may be normally acid and rendered alkaline by the administration of alkaline medicines, or the urine may be alkaline from bacterial decomposition. Take first a normal individual with a sterile, slightly acid urine. In such an individual a single dose of 15 grains of Hexamine was given, and free formaldehyde appeared in the urine in two hours. Twenty grains of sodium bicarbonate were then administered. Half an hour later the urine had become alkaline, and free formaldehyde was no longer present, although Hexamine was being excreted. Forty grains of acid sodium phosphate were then given, and a further dose of 20 grains two hours later. Three and a half hours later the urine was again acid and free formaldehyde was present in quantity.

In this case, on a single dose of Hexamine the urine was made positive to formaldehyde, negative to formaldehyde, and positive to formaldehyde again by merely changing the reaction of the urine. It will be seen, therefore, that the administration of an alkali, together with Hexamine, will prevent the liberation of formaldehyde and destroy its antiseptic action.

Turning now to the cases where the urine is already alkaline. it is of interest to note that a

normal individual who is taking Hexamine regularly may produce formaldehyde at one part of the day, and fail to do so at another. This is due to the varying acidity of the urine. The morning urine is most acid, and in these individuals always shows formaldehyde; but the urine taken after meals during the alkaline tide may show Hexamine, but no free formaldehyde. On adding an acidifying drug, such as ammonium benzoate, formaldehyde is continuously present in the urine.

In cases of phosphaturia, a mild form of which is extremely common, formaldehyde is not liberated, and in such cases sodium acid phosphate, or ammonium benzoate, must be continued with Hexamine before any formaldehyde reaction is obtained.

Cases of alkaline urine, where the alkalinity is due to bacterial decomposition, form a much more important group. In these cases, so long as the urine remains alkaline, no formaldehyde appears in the urine, and therefore no antiseptic action is obtained. The whole question of urinary antiseptics by Hexamine, in these cases, turns upon our ability to render the urine acid. If we are unable to do so, an antiseptic action cannot be obtained with the formaldehyde series of urinary antiseptics.

The degree of acidity necessary for the splitting of urotropin varies somewhat. With litmus paper a faint tinge of red practically always means a negative formaldehyde, and a haze of phosphates has a similar significance. A well-marked red reaction with litmus will usually be definitely positive to the formaldehyde test. When the total acidity is measured more accurately by means of a decinormal soda solution, the point at which the formaldehyde reaction becomes positive varies from $22 \text{ N}/10$ to as high as $32 \text{ N}/10$.

(c) The effect of alkaline urine on bacterial growth.

A source of fallacy in the administration of urinary antiseptics with alkalis was that the alkaline reaction might of itself influence the growth of bacteria. Before the accurate knowledge in regard to the liberation of formaldehyde as the essential factor in the antiseptic action of Hexamine was available, any benefit gained from the alkaline action on bacteria would be ascribed to the effect of the Hexamine, rather than to the alkali. This fallacy no longer remains, for the formaldehyde test is the test of the antiseptic power of the Hexamine and drugs of this series; but a much wider field for investigation is opened by the question as to what effect alkalis, as such, have upon urinary infection.

Where the urine is already alkaline, the administration of alkalis need not be discussed. It is where the urine is acid that some effect might be expected from the administration of alkalis. Cystitis, with an acid urine, is most frequently due to infection in which the bacillus coli communis predominates, or exists in pure culture.

The treatment of urinary infection by the administration of alkalis has been especially used in the pyelitis of childhood; an infection of the renal pelvis with a pure culture of the bacillus coli communis. The alkaline treatment in these cases was introduced, and has been ably advocated by Dr. John Thomson, and is now the settled practice with the great majority of physicians.

Potassium citrate, and potassium acetate, and sodium bicarbonate are the drugs usually given in doses of from 24 to 48 grains, in 24 hours. Under this treatment the urine becomes alkaline either after a few doses or in two or three days. When this has been accomplished the symptoms subside, the temperature falls to normal, the drowsiness and mental oppression vanish, the pain ceases, and the frequent micturition and scalding disappear.

If the alkaline treatment is discontinued, there is a tendency for the temperature to rise again, the symptoms to reappear. Resumption of the alkaline treatment is again followed by disappearance of the symptoms. Eventually, the alkalis may be discontinued altogether, without recurrence of the symptoms.

The remarkable improvement that is observed in these cases has led to the view that the development of the bacillus coli is inhibited, or the growth destroyed by the action of alkalis. Bacteriologists, on the other hand, deny that any disinfectant, or even antiseptic action, is exercised by alkalis, in strengths such as can be developed in the urine. This conflict between clinical and bacteriological work can, however, be explained by following up the clinical history of a case of pyelitis treated with alkalis. It will then be found that after the symptoms have entirely disappeared, and an apparent cure by alkalis been effected, the urine still shows bacilluria. The action of alkalis in pyelitis appears to be a neutralisation of the acid toxæmia produced by the bacillus coli. The cases that are claimed clinically as cures are not cures in the bacteriological sense, for the infection remains; only, the symptoms which were due to the acids, or acid endotoxins, have disappeared.

(d) The effect of diluents and dilute urine on the action of Hexamine.

A not unimportant part of the routine treatment of urinary infection consists in the administration of diuretic drugs and waters. The method of inducing an excessive diuresis is either by the use of such drugs as citrate or acetate of potash, spirits of nitrous ether, theocin sodium acetate, or by means of infusions such as parsley tea, or buchu tea, or by large quantities of plain water, or by means of diuretic waters such as Contrexéville water, Vittel water, Wildungen water, and others.

When the drugs render the urine alkaline, their use in combination with the formaldehyde series of urinary antiseptics is on this account to be avoided; but when the action is largely that of diuresis, as in the teas first named, and the diuretic waters, this objection does not hold. With the use of the Burnam-Rimini test, it will be found that in a patient taking Hexamine, whose urine gives a positive formaldehyde reaction, a large tumblerful of Contrexéville, or other diuretic water will make the formaldehyde disappear from the urine, while the resultant diuresis is in progress. An excessive diuresis such as is produced by these waters, so lowers the acidity of the urine that splitting of the Hexamine does not take place. It is necessary, therefore, in dealing with a urinary infection, to choose between the two methods of treatment—namely, (1) powerful diuresis, and (2) antiseptic action by means of the formaldehyde series of urinary antiseptics. They cannot be used concurrently.

In many cases of advanced disease of the kidneys, a somewhat similar condition of the urine prevails, as, for instance, in the late stage of urinary obstruction from enlarged prostate, or other cause, or extensive destruction from bilateral septic calculus, or in bilateral hydronephrosis. Urotropin is given in such cases in the simple faith that the excretion of Hexamine, and liberation of formaldehyde, will go on as if the kidneys were healthy.

If we were to judge by experience with other drugs, such as potassium iodide, opium, methylene blue, or indigo carmine, we should at once conclude that this could not be the case. From observations on a number of such cases, I have come to the conclusion that there are two factors which reduce the efficacy of urotropin as a urinary antiseptic, in advanced disease of the kidneys. First, there is

diminished excretion of the drug, in a few cases. A larger dose of Hexamine is required before it is excreted in quantity in the urine. Secondly, when Hexamine is well excreted, the condition of the urine in these cases is unfavourable for the liberation of formaldehyde. The urine is copious and neutral, or fairly acid, and it is difficult, and sometimes impossible, to increase its acidity.

(e) Idiosyncrasies in regard to the formaldehyde series.

According to Burnam, not more than two patients out of every ten show liberation of formaldehyde in the urine during the administration of Hexamine. L'Esperance found only 50 per cent. of patients produced formaldehyde, and he considered the reaction of the urine of no importance.

In a series of cases (230) I found 34.3 per cent. negative to the formaldehyde test. In the majority of these cases Hexamine was excreted, but did not split; and in practically all these the cause of the non-splitting was the alkalinity of the urine. In not more than five cases was it impossible to explain, on the lines already indicated, the negative result of the formaldehyde test. Three of these did not split in an acid urine, and two did not excrete urotropin at all. Possibly the solutions with which the test was made were not fresh, and reference to this important point has already been made in describing the tests.

Burnam suggests an idiosyncrasy of certain patients to explain the negative formaldehyde reaction in the urine. It is possible that stale test solutions or other chemical peculiarity may be the explanation rather than a vital action, as Burnam suggests.

APPLICATION OF THE FOREGOING FACTS TO CLINICAL WORK.

I. The treatment of different types of urinary infection.

(a) Acute bacillus coli infection:—Under this term are included a number of distinct clinical types, such as acute pyelitis in the adult and child, and in pregnant women, and acute acid cystitis.

Urinary antiseptics should be laid aside in the acute stage of this infection. A course of alkalis should be given and pushed until the urine becomes alkaline. The alkaline treatment should be continued for three or four days after the temperature has become normal. Examination of the urine may now show that the infection is disappearing, or gone. If it still persists, with a normal temperature, the urine should be rendered acid, and increasing doses of Hexamine given, until the limit of tolerance is reached, and continued until the infection has disappeared.

In acute acid cystitis the use of urinary antiseptics of the formaldehyde group causes an increase in the symptoms, from the contact of the formaldehyde with the intensely sensitive bladder mucous membrane.

The first object that should be aimed at is to soothe the bladder by reducing the acidity of the urine, or rendering it slightly alkaline. It is time enough to commence the urinary antiseptic when the acute symptoms have subsided.

(b) Alkaline Cystitis.

It is obvious from what has already been stated that, so long as the urine is alkaline, the formaldehyde series of urinary antiseptics can have no antiseptic action. Treatment should first be directed to rendering the urine acid by the use of acid sodium phosphate and ammonium benzoate. This has the effect of allaying the intense burning pain, and constant desire to micturate, and at the same time renders the urine suitable for the use of the formaldehyde urinary antiseptics. It will be found that boracic acid is a useful antiseptic in these cases,

and, combined with ammonium benzoate, very rapidly changes the character of the urine, and gives relief. When the reaction of the urine has changed to acid, Hexamine should be added to the mixture.

In prescribing for cases of cystitis, far too little attention is paid to the reaction of the urine. Litmus paper should be used as a guide throughout the treatment. The effect on symptoms, of changing the reaction of the urine from acid to alkaline, or from alkaline to acid, in acute cystitis, quite apart from any antiseptic drugs, is sometimes very remarkable.

2. The limits of urinary antiseptics.

The limitations that idiosyncrasy places upon the dosage of urinary antiseptics in certain individuals has already been noted. In infection of the urinary tract the surgeon early comes to recognise two types. In one type the urinary infection is the only abnormal condition present in the urinary organs, apart from some reaction of the mucous membranes. In the second type some other urinary disease is present, such as stone, chronic prostatitis, or urinary obstruction (hydronephrosis, pyohydronephrosis, enlarged prostate, stricture). In the first class of case, the use of urinary antiseptics is frequently sufficient in itself to cure the infection. One type of case in this class is, however, particularly troublesome—namely, pure bacilluria.

It is sometimes possible by gradually increasing the dose of Hexamine, and at the same time providing an acid urine in which it will split, to cause diminution, and eventually disappearance of the bacilli. Prolonged treatment is frequently necessary, and occasionally it is unavailing, and the bacilluria persists in spite of all treatment. The most persistent cases are those in which no inflammatory reaction of the urinary tract is present. When acute exacerbations occur, these are treated in the manner already indicated.

There are other cases in which it is impossible to obtain a sufficiently high acidity of the urine to produce splitting of the Hexamine. In such cases, and in those where a systematic attempt is being made to render the urine acid by means of acidifying drugs, boracic acid is the best antiseptic drug we possess. In all such cases local treatment by antiseptic washes must be systematically used.

The extent of the infection, and its principal form, must first of all be ascertained by means of cystoscopy, and catheterisation of the ureters. When the bladder alone is infected this should be washed, and where pyelitis is present lavage of the renal pelvis may be carried out.

Turning now to the second class of cases, where some definite lesion is present in addition to the urinary infection.

In a patient with enlarged prostate and an undrained pool of infected urine, or an infected renal or vesical stone, or one with chronic prostatitis or stricture, or pyonephrosis, there can be no hope of ever curing the infection by urinary antiseptics alone. It is necessary to remove the residual urine, or the stone, or to relieve the obstruction. When this has been done urinary antiseptics will complete the cure by overcoming the infection.

3. Urinary antiseptics as prophylactic agents.

Urinary antiseptics have so far only been considered in cases where urinary infection is already established. They have, however, a further use as preventive agents against urinary infection, where the urine is still sterile. This prophylactic action should be used not only when an operation upon the urinary organs is proposed, but also before all operations involving interference with the bowel or other pelvic organs.

In all cases where an instrument is to be passed

along the urethra, an endeavour should be made to render the urine antiseptic by giving Hexamine in doses of 15 grains, thrice daily, and ascertaining, by means of the tests already described, if formaldehyde is appearing in the urine. Similarly, in all operations upon the urinary tract, formaldehyde should be present in the urine before the operation, and continuously afterwards, until the patient is convalescent.

There is another class of cases that is worthy of closer attention than it has yet received. It is not an uncommon experience that after an operation on the bowel, or rectum, or female pelvic organs, or a pile operation, a urinary infection occurs and persists. In some of these cases the catheter has been passed for post-operative retention, and the onus of carrying the infection is, rightly or wrongly, placed upon the catheter; but in other cases no instrument has been passed, and the infection has either passed through the blood-stream, or by lymphatic infection, through the bladder wall. In such cases a precautionary course of urinary antiseptics, with the full development of the formaldehyde action in the urine, could not fail to exercise a powerful effect in deciding whether the infection would develop or be only a passing bacilluria.

I would advise, therefore, that the urinary tract be prepared by a course of antiseptics, just as the bowel is prepared by aperients before all operations where interference with the bowel or pelvic organs is probable, and that this be made a routine before parturition.

OXYGEN AND CANCER.

By LIONEL CRESSWELL,

Burley-in-Wharfedale.

PART I.

In an essay published by me in "The Nineteenth Century and After," for May, 1914, I submitted a series of observed facts tending to show that oxygen is the actual stimulus of the primary malignantly disposed animal cell towards the evil course that culminates in the disease popularly called cancer. Not, be it observed, the ordinary oxygen of the atmosphere, diluted, as that is, with four times its volume of nitrogen, nor even perhaps ordinary or the relatively quiescent molecular oxygen. But more probably oxygen surface-concentrated, condensed and molecularly disturbed, possessing the enhanced chemical properties of such, and possibly possessing the atomic activities of the nascent state. Also there must be a catalytic agent present, soot, for instance, in the case of chimney sweep's cancer, blood decomposition derivatives, such as hæmosiderin or globin in sarcoma, melanin in melanotic sarcoma and ferments, enzymes or oxidases in other cases. These act as condensers, excitants, and carriers. Further, there must be exposure of the cell protoplasm to the chemically excited oxygen. But the cancerous predisposition must co-exist or few of us would escape cancer for any length of time. Mechanical injury opens the door—as it were, admitting the catalytically accompanied oxygen over the cell threshold to the oxygen-starved protoplasm inside. Hence, finally there must exist a condition of "oxygen-hunger" in some of the cells or tissues or organs or in the whole organism, arising from senile decay, general or partial, due to natural inferiority, or failure to a great extent in the oxygen supplying mechanism of the body.

It was impossible, as I indicated at the time,

to assemble together in the limits of a magazine article all the data leading to and supporting my hypothesis. So I contented myself with pointing out that similar reasoning as to the causation of cancer applies in other remarkable forms, such as "Kangri" or "firebasket" cancer, to which the natives of Kashmir are prone, to the penile cancer found among the Hindoos, and to cancer among workers in gas works, tar and other products of heat decomposition, and to gases of cancer incidental to workers where animal and vegetable decomposition and putrefaction are encountered, to cancer incident to the liquor trades and alcoholism, and, finally, to those cases of "arsenic" cancer which have given pause to the farmers of parasitic and other theories affording no room for an inorganic stimulus.

It is this last class of cancer that I propose to consider more fully in this paper. According to Roger Williams (1) workers in soot, tar, paraffin, arsenic, etc., are specially prone to certain cutaneous cancer; and it has been reported that those employed in particular cobalt and nickel mines are prone to quasi-malignant pulmonary disease. Adami and McCrae (2) also tell us that of occupational cancers the most noted are cancer of the scrotum, which used to be common among chimney sweepers in Great Britain—the multiple epitheliomatous sores that are apt to develop in those engaged in the production of paraffin and coal-tar productions and the frequency of similar epitheliomas connected with work in arsenic. According to Paris, cancer of the scrotum, due to the action of arsenious acid, occurs in copper and tin-smelters. Rayer reported cancer preceded by dermatitis among the smelters of arsenical ores. Hesse reported cancer of the lungs—described also as lymphosarcoma—as not uncommon among cobalt miners of Schneeberg in Saxony. The dust of smaltite (cobalt-arsenide) received the blame, and the air of the mines was laden with that. In the Prussian town of Reichenstein, where arsenical mining is an important industry, Geiger found some cases of carcinoma of the fingers supervening upon arsenical warts. Many of the inhabitants suffered from arsenical poisoning due to the arsenic containing water.

A number of observers—Jonathan Hutchinson among them—have reported the onset of epithelioma in psoriatic patients who have gone through a long course of arsenic. In some cases the epithelioma began in the psoriatic lesions, but in others it was preceded by growths situated usually on the palmar and plantar surfaces, but also elsewhere. In the cases mentioned by Rayer, a preceding inflammation was noted, and where epithelioma begins in a psoriatic lesion, the inflammation will be aggravated by the arsenic, a fact which is known to happen.

In one form or another arsenic is frequently employed or encountered in ordinary daily life or work. All its forms, *except the metallic*, are highly active poisons. Arsenious anhydride, more commonly called white arsenic, arsenious acid or merely arsenic, is used for the preservation of wood, and is occasionally thrown into the holds of vessels in large quantities to prevent vegetable decomposition. In India a solution of arsenic is applied to the walls as wash in order to prevent the attacks of insects. It is used in many other non-official and pharmaceutical preparations, such as weed-killers for garden paths and walks, sheep dips, rat and fly poisons, veterinary medicine,

preparations such as Fowler's solution, Clemen's solution, and quack nostrums for external use in cancer. It is found in the white, green, and blue fire dear to the heart of the small celebrant of the anniversary rites of Guy Fawkes. The tasteless "ague drops" formerly used in the malarious districts contained it. Arsenic is used in preserving the skins of animals; one of the compounds for this purpose is known under the name of Becœur's Arsenical Soap. Fellmongers use orpiment and realgar (compounds of arsenic) as depilatories. The pigments called King's Yellow Orpiment, Scheele's Green and Schweinfurt Green are all either composed of it or contain it largely. In many cases arsenic has been discovered where previously there was no suspicion of its presence, notably in beer, the scare and legal proceedings associated with that beverage of some few years back being notorious. Indeed, so frequently is its presence detected that it is possible, as some assert, that it is to be found in everything and everywhere in greater or less amount.

Arsenic is very closely allied to phosphorus in its chemical, pharmacological and therapeutic properties. It occurs in commerce in steel-grey when fresh, afterwards whitish-grey, from formation of a sub-oxide, somewhat iridescent and brittle, crystalline masses, and is obtained by subjecting arsenical pyrites to sublimation in earthen retorts, the arsenic being deposited in suitable receivers on sheet iron. There is an allotropic variety, yellow arsenic, obtained by subliming arsenic in the current of CO₂ in the dark and condensing the vapours on a surface cooled to 0°. Yellow arsenic has an onion-like odour, is soluble in carbon-disulphide, which solution, on evaporation, leaves it in rhombohedral dodecahedronisomorphous, with crystals of white phosphorus. It is rapidly changed with evolution of heat into ordinary amorphous arsenic. *Metallic arsenic is probably not poisonous*, but may be changed by the animal fluids into soluble compounds and then exert toxic effects. Volatilised metallic arsenic is easily transformed in the presence of air into arsenious acid, and is therefore intensely poisonous. Orpiment is a golden-yellow tri-sulphide of arsenic. Realgar is the di-sulphide.

Generally when the term arsenic is used the anhydrous arsenious acid or white arsenic is the substance referred to. It is obtained in commerce on a very large scale from the roasting of arsenical pyrites. As thus derived it is usually in the form of a white cake, the arsenious acid existing in four forms—one amorphous, one vitreous, and two crystalline—the cake being generally opaque externally, whilst in the centre it is transparent. According to Kruger, this change from the crystalline to the amorphous condition is dependent upon the absorption of moisture, no alteration taking place in dry air (3).

The solubility of arsenious acid is often a question involving chemical legal matters of great moment. No precisely definite statement can be made on this point since amorphous and crystalline varieties have very unequal solubilities, and they occur in very different proportions in different samples. Taylor's (4) statement is accepted as approximately correct, namely, that an ounce of cold water dissolves from half a grain to a grain. If boiling water is used, or if the white arsenic be boiled in water, the proportion dissolved

is raised very considerably. Potash and soda readily combine with it to form soluble salts. Among other arsenical compounds is arsine or arseniuretted hydrogen, a colourless inflammable gas of a foetid alliaceous odour and intensely poisonous. The discoverer of the gas, the chemist, A. F. Gehlen, of Munich, died from its effects in 1815. When preparing the gas he went smelling about the joints of the apparatus for a leak and inhaled some. He was immediately seized with nausea, vomiting and great exhaustion, and died at the end of nine days. Brittan, of Dublin and a professor at Santiago, in Chili, were poisoned in the same way as recently as 1892. Arseniuretted hydrogen destroys the red blood corpuscles and decomposes the oxyhæmoglobin. *The effect on the latter, as shown by spectrum analysis, is the same as is observed after the action of ozone, and of sulphuretted hydrogen, and also in putrid blood, a dark band appearing in the red in the place of that of methæmoglobin.*

Effects of Arsenious Acid on Plants.—If the root or stem of a plant is immersed in a solution of arsenious acid, the hue of the leaves soon alters in appearance; the green colour becomes of a whitish or brownish hue and the plant withers, the effect being very similar to that produced by hot water. The toxic action may be traced from below upwards, and analysis will detect minute quantities of arsenic in all portions of the plant. But it is said by one observer that if arsenious acid be mixed with earth and plants grown in such earth they only take up infinitesimal quantities of arsenic. (5).

Effects on Animal Life.—All infusoria and forms of animalcule-life hitherto observed perish rapidly if a minute quantity of arsenious acid is dissolved in the water in which they exist. The common arsenical fly papers exhibit the action of arsenic on ordinary flies. Within a few minutes the flies fall, apparently from paralysis of the wings, and die. Spiders exhibit a similar sudden death. Annelids, birds, etc., all succumb to its effects. Mammals, such as cats, dogs, etc., suffer from symptoms fairly identical with those observed in man, which vary according to the form of the poison—whether solid, vaporous or soluble—according to the condition of bodily health of the person taking it, and according to the manner in which it is introduced into the animal economy. They are also modified by individual peculiarities or organisation and by habit, as, for instance, in the arsenic-eaters of Styria and India (6).

Large doses produce poisonous effects on human beings, *violent inflammation of the stomach and intestines* being the characteristic symptom; death results from paralysis of the heart and of the respiratory centre, consciousness is retained almost to the last. The inflammation of the stomach and intestines presents characters similar to those produced by phosphorus. In rapidly fatal cases gastro-enteritis may be entirely absent, and death takes place simply from paralysis of the nervous centres. *Gastro-enteritis is produced essentially through the agency of the circulation.* If arsenious acid or one of its salts is injected subcutaneously in the back of an animal no corrosive action is perceptible at the puncture. On the other hand, unless the poison produces rapidly fatal paralysis we find after a few hours violent inflammation of the stomach and the whole of the small intestine. In any case when arsenic is brought into contact externally with

living tissue it acts as a caustic only after a considerable interval, and it produces its effects on distant parts only after it has been in some way or other absorbed into the system. It possesses no recognisable direct affinity for albumen, and in the words of Buckheim (7) "it is probably only in the organism that it is transformed into a poisonous compound. . . ." That author further observed, "We are at present unable to indicate with any degree of probability the nature of the combination by which the effects of arsenic are produced."

Externally arsenious acid is a powerful caustic when applied to raw surfaces, though it has little action on the unbroken skin. In certain forms of anæmia it increases the number of the red corpuscles and also their hæmoglobin content. Externally arsenious acid has been much used by quack doctors to destroy morbid growths, etc., a paste or solution being applied strong enough to kill the mass of tissue and make it slough out quickly. But many accidents have resulted from the arsenic being absorbed and the patient thereby poisoned. *Metallic arsenic is probably not poisonous, but as it usually becomes oxidised in the alimentary canal the symptoms of arsenical poisoning follow its use.* (8).

"The older view with regard to the essential action of arsenic was that the effects were mainly local, and that death ensued from the corrosive action on the stomach and other tissues, a view which is in its entirety no longer accepted. It is true that arsenic has a corrosive local action, it will raise blisters on the skin, and will inflame the tongue or mucous membranes with which it comes in contact. The curious fact that when arsenic is absorbed from a cutaneous surface or from a wound, the mucous membrane of the stomach inflames, is explained by the absorption of the arsenic into the blood and its separation by the mucous membrane, in its passage exerting an irritant action. Binz has advanced a new and original theory as to the action of arsenious acid; he considers that the protoplasm of the cells of any tissues possesses the power of oxidising arsenious acid to arsenic acid, and this arsenic acid is again, by the same agency, reduced to arsenious acid. In this way by the alternate oxidation and reduction of the arsenious acid the cells are decomposed and a fatty degeneration takes place. Thus arsenic causes fatty changes in the liver, kidney and other cells by a process analogous to the action of phosphorus. T. Araki also considers that both arsenic and phosphorus lessen oxidation, and points out that lactic acid appears in the urine when either of these poisons is taken, such acid being the result of insufficient oxidation." (9).

I found it worth while examining Binz's theory at first hand.

"We (Binz and Schulz) started with the assumption that arsenic, which behaves both as a triad and as a pentad element, could act as a carrier and as a discharger of loosely combined oxygen, just in the same way as the triad and pentad nitrogen; arsenious acid corresponding with NO and arsenic acid with NO₂.

"NO (oxide of nitrogen, nitric oxide) acts as a caustic on animal tissues, combining with oxygen it is converted into the red fumes of the strongly oxidising agent NO₂. Nitric peroxide NO₂ destroys the tissues, as it is decomposed by water and reconverted, in part at least, into NO.

Nitrogen itself takes no direct part in these changes; it is simply and solely the carrier and distributor of the energetic atoms of oxygen.

"When the nitrogen in the animal tissues discharges or combines with oxygen the tissue undergoes considerable destructive change. Are these same tissues also capable of developing in arsenic this varying absorption and discharge of oxygen? The well-known facts that arsenious acid is a powerful reducing agent, and that arsenic acid is a still more powerful oxidising agent lent a certain probability to the answer being in the affirmative.

"It would occupy us too long if I entered into all the details of the experiments which were made on different parts of the animal body. I will merely state that the tissues were recent, and when necessary were cut into small pieces; they were then placed into the neutral solutions of sodium *arsenite* and *arsenate* and digested at blood heat. The subsequent chemical examination invariably showed that in the presence of living protoplasm arsenious acid was oxidised into arsenic acid and that the latter was also reduced to arsenious acid, but acted in a strongly marked manner as a reducing agent on arsenic acid.

"The mucous membrane of the stomach, the pancreas and the brain have an oxidising power on arsenious acid, the power of those tissues increasing in the order given; they have also a reducing power on arsenic acid, the activity of the tissues being in the reverse order. This reverse order may arise from the As_2O_3 , which results in the reduction of the As_2O_5 , constantly undergoing re-oxidisation. The same effects are produced by the liver, which appears to possess the highest oxidising power of all the viscera with which we experimented.

"It is only by *living* protoplasm that arsenious acid undergoes oxidation, when thoroughly boiled—that is to say, when dead—protoplasm has no such action.

"Following upon these experiments which were made with organic tissue in a dying state, we had still to prove that changes similar to those described above took place when the two arsenical oxides were brought in contact with the living tissues of living animals."

Binz here recites certain experiments:—"After each experiment it was found by careful chemical analysis, that both oxides of arsenic were present in the intestines, though only one of the oxides had been injected.

"So far we have arrived at the following facts:—

"1. In the animal organism arsenious is converted into arsenic acid, and arsenic acid is likewise converted into arsenious acid.

"2. These two transformations are rapidly produced, both within the body and outside it by means of protoplasmic tissue.

"3. The experiments performed outside the body demonstrate that the viscera which are more particularly affected by arsenic during life are precisely those by which arsenious acid is readily oxidised.

"Arsenic, therefore, must be regarded merely as the carrier of oxygen, the latter being the active agent. This hypothesis, which undoubtedly is opposed to the theories previously advanced as to the action of arsenic, has nothing out of the way or unusual about it. The results of our experiments justify us in saying that there is

no reason against assuming that arsenic may probably possess certain qualities the existence of which has been demonstrated in the case of nitrogen.

"The destructive changes which are brought about by oxygen can be clearly demonstrated by another example which is of daily occurrence. Ferric oxide continuously furnishes to organic tissues an atom of oxygen, and is reduced to the form of ferrous oxide. This, however, cannot exist in the presence of air or water, and is almost instantaneously reconverted into ferric oxide. The organic tissues are wasted or consumed by this continuous interchange of oxygen. The timbers of a ship at the spots through which nails have been driven present a half-charred appearance. Spots of rust on linen cause it to rot and fall into holes. Organic substances in the soil are decomposed under the action of ferric oxide. The ferrous oxide lying in the deeper layers of the soil is turned up by the plough and being converted into ferric oxide produces the result above mentioned.

"The following table enables us to compare the changes which nitrogen, iron and arsenic respectively undergo in accordance with the properties described above:—

NO becomes NO_2 and is reconverted into NO.
 $2FeO$ " Fe_2O_3 " " " $2FeO$.
 As_2O_3 " As_2O " " " As_2O_5 .

These several processes differ in regard to each element only by the rapidity with which they take place. With nitrogen the change occurs very quickly, with iron slowly; arsenic occupies an intermediate position. If an ointment or paste containing arsenious acid is applied externally to parts from which the epidermis has been removed, some hours always elapse before any burning sensation is felt. Nitric oxide produces this effect instantaneously.

"We must not omit to mention here the difference in the mode of action of the two oxides of nitrogen and of arsenic. The former produce their destructive effects on the parts to which they are applied; the latter only within the tissues.

"This difference is of no importance as far as we are concerned, and it does not affect the argument, and it has no real existence. We are in fact able to develop the corrosive oxides of nitrogen within the tissues, and we then see how completely the effects resemble those of the arsenical oxides. On this point I would refer you to what I have previously said when discussing the effects of sodium nitrate.

"By further investigations Hugo Schulz and I have confirmed and extended our theory that oxygen is the prime factor by which the effects of arsenic are produced.

"In the first paper which we published on the subject we called attention to the fact that the action of the arsenites on the alkaline mucous membrane of the intestines was stronger than that of the arseniates. We thereby confirmed the statements of previous authors, who maintained that, given the same amount of metallic arsenic, the arseniates were more rapidly poisonous and produced death more quickly in healthy animals than the arseniates. The nature of the effects produced is, as is well known, precisely the same; it is with regard to the rapidity of their action that they differ.

"When arsenious acid is introduced into the

circulation, and thereby passes to the glandular organs in the abdomen or to the central nervous system, it rapidly deoxidises or reduces the protoplasm of these organs, and is itself converted into arsenic acid. The latter is in the capillaries and veins very readily again reduced to arsenious acid and is then capable of repeating its action on the protoplasm as often as it is carried to the latter. The process thus goes on continuously so long as the arsenic remains in the system.

"I may also mention here that such organs as the liver and kidneys, which are more particularly sensitive to the action of arsenic, and which rapidly undergo change in consequence—a point which I myself have demonstrated as regards the liver—absorb and retain a larger quantity of the drug than those which are less sensitive to its effects. This is a further proof of the close affinity which exists between certain cells and arsenic.

"I then proceed to test the effects of arsenic by experiments similar to those I described when referring to phosphorus. These experiments confirmed the conclusions drawn from other facts, namely, that arsenic only acts as a caustic when in contact with *Glandular Tissues*, whereas connective tissue is almost unaffected by it.

"The similarity in chemical and toxicological behaviour of the tri- and quinque-valent elements is very remarkable. This group consists of nitrogen, arsenic, phosphorus, antimony, bismuth and vanadium.

"Nitric Oxide (NO) is a strongly reducing agent; Nitric Peroxide (NO₂) is a powerful oxidiser. It is these properties that unquestionably render them so destructive to tissue. The nitrogen takes no direct part in the process; this is entirely dependent on the combined oxygen, which constantly varies in amount, becoming nascent, active, atomic, or whatever other name you like to give it.

"Phosphorus behaves in a similar manner." (Similarly, also, although in varying degree, as Binz shows, antimony, bismuth and vanadium).

It is proposed to establish a course of military medicine in the medical school of Harvard University, under the supervision of Major Westons P. Chamberlain, of the the United States Army.

It is understood that Germany is purchasing seaweed, for the purpose of making iodine, wherever she can, and the German shores are cleared of seaweed day by day.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CONSCIENTIOUS OBJECTOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Percy Biggs suggests that I wrote to you on this subject in order to "get a page in your valuable journal . . . to state opinions on the conscientious objector which he considers are incorrect." His perspicacity is continuous. Such was my object, and the result has been to draw from him a statement of his views which shows him to be illogical, confused, or ignorant in psychology, and unpatriotic—illogical, because when he defines the characteristics of his class he rests on the fallacy of the patriotic principle, he begs the question; ignorant of psychology, because he confounds conscience with conscientiousness; unpatriotic, because he prefers to save himself at the expense of his compatriots who obey the behests of the King, of the chosen leaders of the policy of the country, and of the teaching of the Bible itself. Mr. Biggs's conscience is a non-existent phantom, it is a relic of the old false assumption that there is a special faculty which directs what a man should or should not do, whereas it is clearly shown by modern psychology that there is no such faculty, but that what exists really is a state of consciousness which is not a primary faculty at all, but is the result of the physical processes which the various environmental excitants bring about in the brain. In this case for the consciousness to be a right-minded complex the elements of it must be of the proper kind—viz., obedience to authority, patriotism, unselfishness, courage, and duty to your neighbour. In most of the conscientious these components are wanting, so that the complex, or the "content of conscientiousness" is useless to the country—it is a selfish consciousness, and if universally held would end in physical annihilation and spiritual degradation. If Mr. Biggs would favour me by reading the chapters on "Conscientiousness" in my book, "Ex Cathedra Essays," he would, perhaps, have a better conception of the subject. I mention this, not as an advertisement, but charitably to help Mr. Biggs.

I am, Sir, yours truly,

T. CLAYE SHAW, M.D., F.R.C.P.

London, W.

April 2nd, 1916.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of your correspondent Mr. Percy Biggs, in reply to Dr. Claye Shaw, is amusing as an attempt to bolster up what he is pleased to call his conscience. For the conscience of a so-called conscientious objector is only a man-made affair. Certainly religion lends no support to this unstable contention. If he thinks it does he is mistaken, and religion is the highest tribunal to which he can appeal. Is there a word in the New Testament condemnatory of the battles fought against, say, the Amalekites, by the Israelites of old? Was not the extermination of the idolatrous tribes one of the chief duties which the Israelites were called upon to perform? And have not the Huns in this war placed themselves upon the same level as the Amalekites, and do they not deserve the same punishment? But let us go a little further and carry the conscientious objector's attitude to its logical conclusion—to what does it lead? Let us suppose that every man in this country, including

also those manning our fleet and those fighting our battles, "downed tools" because of conscientious objection to warfare, what would become of the nation? We should soon find ourselves a vassal of Germany, and we should merit our punishment by the wilful neglect to exhibit that priceless possession of a nation—patriotism. If a "conscientious objector" can ignore patriotism in the present crisis of his country's need, then he is only fit for a prison camp in Germany. He is certainly not entitled to the advantages gained for him by our forefathers in battles which have entitled us to live as a free nation.

I am, Sir, yours truly,
F.R.C.S.

London.

March 31st, 1916.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. T. Clave Shaw has been furnished by Mr. Percy Biggs with a text for amplification of his extremely interesting and suggestive article. The psychology of the conscientious objector will evidently bear further examination, and all your readers will hope to find this examination carried out by Dr. Clave Shaw.

With psychology I do not deal, but from the sociological point of view one might characterise Mr. Biggs's tenets, if they were not so pitiable, as merely grotesquely absurd. These tenets, if carried out to their logical conclusion, would mean the breaking up of civilised society and the substitution of a government of criminal lawlessness. This can be best illustrated by concrete examples. We all recollect the story of the Stepney anarchists. If Mr. Biggs's opinions had been applied in this case the government of London, or even the whole British Empire, might have been left in the hands of these brigands, reinforced by the larger band of their brethren then living in the East End. These men resisted arrest, barricaded themselves in a house, and shot down, wounded, or killed some six or more policemen who ventured to approach. The police, reinforced by soldiers, opened fire in return on the house, and in the end the murderers were either shot down or perished in the fire which later destroyed the building. No doubt it is deplorable to have to commit such justifiable homicide, and it will no doubt be possible to abolish manslaughter of this kind when murderers cease to appear.

Mr. Biggs's creed in operation would mean the abolition of private ownership. How do the Society of Friends, who are mostly well-to-do and wealthy, safeguard their worldly possessions? If, for example, their deeds and securities are deposited with their banker, it is always possible that a conflict with the police and a gang of armed burglars would lead to the slaughter of some of the robbers. A military guard with fixed bayonets and ball cartridges is on duty at the Bank of England every night. It must seem most immoral in Mr. Biggs's opinion to run the risk which an assault upon the Bank by armed robbers might entail. Then the case of the householder. He must be bound to receive, with words of peace, a party of robbers, whether armed or not, who might pay him a visit at night. He must not oppose them himself by force nor call up the police. He ought not, indeed, to pay the police rates. He ought carefully to inculcate to the female part of his household the necessity of not resisting any insult that might be offered by the thieves, and not to seize any available weapon to defend themselves against foul outrage. They might, perhaps, slay their assailant—a heinous crime according to Mr. Biggs's reasoning. It is not worth while labouring this argument

further. It is amazing to see that a man who can write so clearly as Mr. Biggs should be capable of putting forth such ideas.

Similar considerations obviously apply to international relations. According to Mr. Biggs, Belgium ought to have prostrated herself before Germany. France ought to have fallen on her knees, and whilst accepting the position of vassal to Germany, should have exchanged German Kultur for the freedom of thought and research which have been the glory of her ancient and modern universities. We, for our part, ought to have welcomed with peaceful cries the Kaiser and his army to our shores, and should have witnessed with abject subjection his coronation as king of these realms, Emperor of India, and Over-Lord of our Dominions and Colonies.

Mr. Biggs's views are not really shared by the Society of Friends. A large number of young Quakers volunteered to the Ambulance Corps at the outbreak of war, and many of them have been wounded or killed while acting as stretcher-bearers at the Front. These brave fellows were not so stupid that they could not see that each of them was setting free a fighting man who, without their help, would have been needed for the duty they had taken on. Everybody who knows much about the Society of Friends is aware that they form but a small community, which is rapidly dwindling. In former times they were kept apart by persecution. The triumph of religious freedom in these islands has formed the main cause of this decay. In time of peace their illogical and unpractical attitude does no harm—many of them lead noble lives of continuous self-sacrifice. But in the stress of war, such as we are now enduring, fantastic theological arguments cannot release responsible citizens from the obligations of serving their country when called upon, and if they will not serve voluntarily, the State has surely the right to compel them.

I am, Sir, yours truly,
A STUDENT OF SOCIOLOGY.

March 31st, 1916.

IRISH MEDICAL SCHOOLS' AND
GRADUATES' ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It will interest your readers to learn that the above Association on St. Patrick's Day presented the Arnott Gold Medal for bravery to Capt. W. Loughman, R.A.M.C., of Dublin, for conspicuous gallantry at the front.

I am, Sir, yours truly,
SHEPHERD BOYD,

7 Springfield Avenue, Harrogate, Yorks. Hon. Prov. Sec.
March 25th, 1916.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASES IN CHILDREN.

MEETING HELD MARCH 24TH, 1916.

The President, DR. R. HUTCHISON, in the Chair.

DR. HUGH THURSFIELD showed a case of rickets; multiple fractures, in a girl, æt. 2½, with old fractures of both clavicles, both femora, and both humeri, and recent fractures of right humerus and left fibula and tibia. She had marked rickety deformity of the thorax.

Dr. H. C. CAMERON showed a case of osteogenesis imperfecta in a girl, aged 5 months. Three other children in the family. No history of fractures in any relatives. Born at full time. The baby was small, though not ill-nourished. On admission, there was tetany of the hands, and the spasm could be made very marked by rendering the hand cyanosed by the pressure of an elastic band around the upper arm. In a few days this disappeared. Until admission the baby was breast-fed. The shape of the skull was typical. The antero-posterior axis of the eyeball pointed downwards as a result of changes in the shape of the orbit. The skull presented a superficial resemblance to that of hydrocephalus of mild degree. The limbs were somewhat curved and a little short. A thickening due to callus could be felt in the shaft of the right femur. The sclerotics were somewhat blue.

Dr. J. L. BUNCH showed a case of papulo-necrotic tuberculide. The patient was a boy, *æt.* 17. The eruption had begun when the child was aged four years, as a single red patch at the navel, on which small red nodules had developed later. The nodules were slightly raised, somewhat papular in character, and distinctly infiltrated. They had a tendency to necrose, and always left a superficial, shallow scar about one-eighth inch to one-third inch in diameter. The disease was evidently still progressive, for, when shown at the meeting there was a well-marked raised red papule on the abdomen which had made its appearance during the past week, such as always went on to the formation of a depressed, atrophic scar. The boy attended school regularly, and was not inferior in physique to other boys of his own age; there were not, and never had been, any signs or symptoms of lung trouble, but occasionally there had been enlarged glands. Since 1906 the disease had continually progressed, always in much the same manner, but more recently definite ulcers had been present on the legs and an unusual form of alopecia had shown itself. Guinea-pig inoculations were positive. All kinds of treatment had been tried: tuberculins of various nature and in various doses, X-rays, and local applications of all kinds.

Dr. J. L. BUNCH also showed a case of molluscum contagiosum. The boy had a number of typical molluscum lesions, but in an unusual position. They were situated in the right groin and were in various stages of evolution. The usual positions—hands and face, etc.—were quite free from lesions.

Dr. BUNCH also showed a case of multiple lupus vulgaris. The patient, a girl, *æt.* 5, developed 44 patches of lupus vulgaris after measles. The patches were of various sizes and situated on the face, trunk and limbs. The lesions had been scraped and X-rayed in addition to other local treatment in some cases; and were now cured.

Dr. J. D. ROLLESTON showed a case of transient hemiplegia in diphtheria and diphtheritic onychia. The patient, a boy, *æt.* 5, was admitted to hospital on October 6th, 1915, with severe faucial diphtheria, on the third day of disease. 20,000 units of antitoxin were given on admission, 16,000 on October 7th, and 12,000 on October 8th. The throat became clean on October 11th. An urticarial rash appeared at the injection site on October 12th, and persisted till October 15th. The same day the heart, hitherto normal, showed some left-sided dilatation and an occasional extra-systole, and the child vomited. On October 16th triple rhythm developed and the liver became enlarged. On November 2nd the voice became nasal. In the morning of November 3rd, the thirty-first day of disease, a circinate rash appeared on the limbs. Temperature, 97.8° F. During the day he complained of abdominal pain, and at 10 p.m. became very pale and almost pulse-

less. At 1.30 a.m. the face, eyes, and arms twitched, and between 4 a.m. and 6.40 a.m. he had general convulsions. At 11.20 a.m. he was found to have complete loss of power in the right upper and lower extremities. He seemed to understand what was said to him, but could not speak. The following morning he had quite recovered his speech and could move his right arm and leg freely. The right plantar reflex was still extensor, but became flexor the next day. The voice remained nasal until November 29th, but no other nervous symptoms developed, and when he was allowed up, on December 3rd, the sixty-first day of disease, he could walk without support. On January 19th, a culture taken from the lesion on the middle finger showed numerous groups of diphtheria bacilli, and 8,000 units of antitoxin were injected. Within a week the lesions, which had been in existence for two and a half months, had completely healed. On his discharge from hospital the left index, ring, and especially the middle finger showed some deformity and ulnar deflection of the terminal phalanges. There was marked limitation of movement of the terminal phalanges of the index and middle fingers, from which nearly all the nail had disappeared.

Dr. E. B. GUNSON showed a case of gangrene of the leg following diphtheria. The patient, a boy, *æt.* 6, was admitted to hospital on January 5th, 1915, with severe faucial diphtheria on fourth day of disease. He was given 20,000 units of antitoxin on admission, and again on the following day. On the seventeenth day the pulse became markedly irregular, the onset of arrhythmia being followed by a marked increase in cardiac and liver dulness. On the eighteenth day there was a sudden onset of acute pain, referred to the right popliteal space. On the following day a ring of discoloration appeared below the knee and the leg became cold. Gangrene of the right small toe and outer aspect of the foot developed on the twenty-second day, and gradually involved the whole of the leg below the level of the knee-joint. Sloughing of the skin appeared at the line of demarcation on the forty-ninth day. Palatal, pharyngeal and diaphragmatic palsies developed during the fifth and sixth weeks. Amputation of the right leg was performed by Mr. H. S. Clogg, the patient ultimately making a complete recovery.

Dr. C. O. HAWTHORNE showed tracings of a case of rapid respiratory rhythm apart from other evidence of disease. The patient, a girl, *æt.* 8, was under observation in hospital for some six weeks, and no evidence of organic disease was discovered. The respiratory rate was constantly quickened (60 to 80 per minute), and occasionally exceeded the pulse rate; when the child was asleep, however, it fell to 20 to 25. There were no other symptoms, and save for the rapid breathing the child seemed to be in a normal state of health. When she left the hospital the respiratory rate was about 40 per minute.

Dr. C. O. HAWTHORNE also showed a case of acute nephritis without œdema; recovery. The patient, a girl, *æt.* 9, was sent into hospital as "probably a case of intestinal obstruction"; the recent history was of constipation with persistent vomiting of forty-eight hours' duration. Physical examination negative, but for several days urine scanty (8 oz. to 10 oz.), with albuminuria (Esbach 3.5) and numerous epithelial, granular and hyaline tube casts; no blood. Early cessation of vomiting and urine normal at the end of a fortnight. No œdema at any time; maximum sphygmometer reading 85 to 90; no evidence of cardiac hypertrophy; brachial arteries palpable, but not in excess of those in other children of same age; and ophthalmoscopic examination negative. No clinical evi-

dence of specific disease, and Wassermann reaction negative.

Dr. E. A. COCKAYNE showed a case of congenital scleroderma and sclerodactylia. The patient was a male, *æt.* 2. First child. Parents healthy. Mother was quite well during pregnancy and has had no miscarriages. The child was born prematurely at the eighth month, and was said to have weighed only 2½ lb. at birth. When first seen at the age of seven months he weighed 9 lb. 4 oz. There was hydrocephalus, the head measurement being 16½ in. The Wassermann reaction was negative. There were dilated veins over the scalp, which was almost devoid of hair, and the eyebrows and eyelashes were almost entirely absent. The skin of the face was thickened, shiny and atrophic, especially on the ears and *alæ nasi*. In the lower limbs, the outer aspect of the thighs and the whole of the skin below the knees was thickened. Growth had been very slow, the weight having been 10 lb. 8 oz. in March, 1915, 11 lb. 2 oz. in August, 1915, and 11 lb. 8 oz. in February, 1916. There was persistent conjunctivitis, and during last summer there was inflammation of the cornea, with subsequent formation of *nebulæ*. Nystagmus is now present. Treatment, first with mercury and then with thyroid extract, was carried out for some months without appreciable effect.

Dr. E. A. COCKAYNE also showed a case of paroxysmal hæmoglobinuria. The patient, a boy, *æt.* 7, lived in India until March, 1915, where he suffered slightly from malaria. There was a history of a miscarriage before he was born, and of a still-born premature child two years ago. The first attack of hæmoglobinuria occurred the day after landing in England. He was free in the summer, but in the autumn, with the onset of cold weather, attacks had occurred fairly often. Previous to the attack the ears and feet felt very cold, but there were no definite phenomena of Raynaud's disease. The child was thin, red-haired, and very anæmic. No definite stigmata of congenital syphilis. The urine during an attack was coffee-coloured and contained hæmoglobin and methæmoglobin, but no red corpuscles and no casts. Wassermann reaction strongly positive.

Dr. J. D. ROLLESTON showed a brain of a mongolian imbecile. The patient was a female infant, aged 12 months, the youngest of eight children, who died of severe faucial and laryngeal diphtheria, complicated with broncho-pneumonia. The brain of a normal infant of the same age who also died of faucial and laryngeal diphtheria, complicated by broncho-pneumonia, was exhibited to show more clearly the following features of a mongol's brain:—

- (1) Reduction of the antero-posterior diameter. The brain, as a whole, was short and oval.
- (2) The large and flat character of the convolutions.
- (3) The shallowness of the secondary sulci.
- (4) The deficient vascularity.
- (5) The small size of the pons, medulla, and cerebellum.

The brain, as a whole, was a good size for an imbecile's brain. Its weight was 836.32 gm., as compared with 816 gm.—the normal weight of a female infant aged 1 year. There was no obvious asymmetry nor any localised macroscopic lesion.

Dr. H. C. CAMERON showed a skeleton from a case of osteogenesis imperfecta, aged 2 months. The birth had been premature and the deformities had been noticed from the first. The frontal suture was persistent and widely separated. The anterior, posterior and lateral fontanelles were all widely patent. The bones of the skull were very thin. The orbits were oval and the long axis vertical. In the temporal region the walls of the cranium were

formed almost entirely of membrane, and the position of this membranous area corresponded with that of the bulging above the ear which was so marked a feature later in life. Almost every rib was fractured once, and some were fractured twice.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, FEBRUARY 18TH, 1916.

DR. R. J. ROWLETTE in the chair.

EXHIBITS.

CULTURES OF TUBERCLE BACILLI.

Dr. W. D. O'KELLY exhibited cultures which were prepared in connection with the work he was carrying out under Professor McWeeney for the Medical Research Committee. They illustrated the cultural points of differentiation between the bovine and human types of tubercle bacilli. He fortunately succeeded in making direct cultures on the egg medium, thus getting over the difficulty of isolating the organisms without animal inoculation. The only difficulty now was to secure the material uncontaminated; if this were obviated a high percentage of successful direct cultures should result.

Dr. BRONTE exhibited cultures of tubercle bacilli of human, bovine and avian type.

ECTOPIA VESICÆ.

Dr. BOXWELL showed organs removed from a female patient, aged 28, on whom Mr. Henry Stokes had previously performed an operation for the cure of ectopia vesicæ. After removal of the uterus, the ureters had been successfully transplanted into the rectum, and for some time the patient had done very well. Subsequently, however, one of the ureters had broken loose from its new point of attachment, probably through defective blood supply in the button of mucous membrane left around the end of the transplanted ureter. A pelvic abscess then formed which opened into the vagina, through which urine was thenceforward voided. The patient ultimately died three months after the operation of ascending pyelonephritis in both kidneys.

The interest of the exhibit mainly lay in the relative rarity of this malformation in a female, and in the condition of the surviving ureteral papilla in the rectum. This was quite pervious, and apparently firmly attached, but was in a condition of superficial necrosis, all the transitional epithelium having perished, with the exception of one tiny shred on its mucous surface, as shown in microscopic sections. This patient had passed for a boy until the date of the first operation, and neither she nor her people were ever disabused of this impression. She had a slight boyish figure, rather hairy arms and legs, and a deep-toned voice, but had total absence of circum-oral hair and had the well developed breasts of a woman.

SPONTANEOUS TUBERCULOSIS IN A RABBIT.

Professor METTAM showed a specimen of above.

The subject was a buck Belgian hare-rabbit kept for stud purposes in the laboratory. It had been in the stock of animals for more than twelve months. During the whole of this time he had not been exposed to infection. He was in normal health until he had an injury to the scrotum, which had apparently been wounded, and looked gangrenous. The part healed without leaving any bad effects. Some time afterwards he was found to have lost condition; he was thin and had lost vigour; indeed he was very weak, and moved

cautiously and slowly, and was inclined to fall over. He had developed a bad attack of auricular acariasis, the auditory canal on both sides being blocked with inspissated pus, desquamated epithelium and numerous acari. (*Psoroptes communis var. cuniculi*.) Shortly afterwards he died. At the *post mortem* examination both lungs contained numerous tubercle-like lesions. No visible lesions were to be observed in the liver. Both kidneys were affected, chiefly in the cortex. No lesions were found elsewhere in the internal organs. The body was very thin. Smears made from the lung lesions revealed the presence of numerous acid fast bacteria. They were not only acid fast, but they also resisted decolourisation by alcohol.

The lung lesions were mostly of some age, necrotic or caseous, some undergoing calcification. Giant cells were few and those seen were at the periphery of the lesion. Numerous bacilli were found in the lesions. Lesions were present in the liver, microscopic and very recent, a generalisation apparently having taken place. The lesions in the kidney approximated in age to those of the lungs, and they also contained acid fast organisms. At the *post mortem* examination cultures were made and a portion of one lung was broken down in a sterile mortar with normal saline and inoculated into the peritoneum of a rabbit, and subcutaneously into the thigh of a guinea-pig. The rabbit was destroyed seventeen days later and a *post mortem* examination made immediately. There was a small quantity of fluid in the peritoneum. The spleen was enlarged, granular, turgescens as in early experimental tuberculosis. In smears a few acid fast organisms were found. The mesenteric lymph gland contained a few acid fast bacteria. There were no naked eye lesions in the gland. In the cæcum and in the large colon remarkable lesions occurred, doubtless the result of the bowel wall being wounded and infected at the time of inoculation. The wall of the bowel was one-third inch thick, firm and fleshy in appearance over an area equal to that of a florin. The mucous membrane was not ulcerated, nor were there any signs of caseation. A scraping from the lesion showed some acid fast bacilli present. The liver was cirrhotic, but contained a few pin-point lesions of a whitish colour, and one acid fast bacillus was found in a smear made from the organ. No lesions were observed in either the lungs or the kidneys. Cultures were made upon inspissated blood serum from the spleen, and an emulsion of the last inoculated into the peritoneum of another rabbit. A microscopic examination of sections made from the lesions of the experimental rabbit (1) showed their tuberculous nature. There was a miliary tuberculosis of the spleen and liver. The lesions in the wall of the intestine were also tuberculous. Acid fast bacilli were found in the bowel lesion. The guinea-pig developed a tuberculous ulcer at the site of inoculation from which issued a discharge containing numerous acid fast bacilli, and the anterior crural lymphatic glands were involved. The ulcer eventually healed and the glands declined in size, and the guinea-pig was still living, six months after inoculation. Rabbit two, inoculated with spleen emulsion of the first experimental rabbit was killed by asphyxia 120 days later, and a *post-mortem* examination made. The animal had lost condition, and was very thin. There was a small lesion on the abdominal wall at site of needle puncture. No peritonitis. Lesions were present in both kidneys up to a pea in size, and situated especially at the poles of the organs. Lesions were present in the cortex extending in some cases into the boundary layer. They were white, firm, and not typically caseous. Acid fast bacilli were found in the lesions.

Spleen swollen, rounded borders, no naked eye tubercles. Few whitish specks in the liver. Minute tubercles in the lungs were just visible to the naked eye. There were also present lesions in the epididymis of both testes. Cultures were made from different organs upon blood serum. The cultures in many instances proved to be contaminated, but after some trouble an uncontaminated growth of an acid fast bacillus was obtained. This was now in the third generation, and it was intended to carry out an investigation of the pathogenic properties of the organism. Cultures up to the present had not been abundant, and growth was slow, but the growth when removed by the needle was easily made into a film on the slide. The organisms were readily dissociated and did not remain in clumps as in making a smear of growths of mammalian tubercle bacilli. In this respect the cultures were similar to the avian tubercle bacillus, but this organism usually grew readily, the culture being fatty in appearance and white. Professor Mettam said that when he had completed his researches he would bring forward a further communication on the subject.

MELANOTIC TUMOUR; METASTASES IN LUNGS, LIVER; PORTAL THROMBOSIS AND CIRRHOSIS IN LATTER.

Dr. J. H. POLLOCK showed specimens of above. *Clinical history*.—Male, past middle life, of alcoholic habits. Admitted with a profound degree of ascites. A large, intensely black, freely movable tumour was found above right elbow joint; and a large, firm mass in the right axilla. There was a history of laceration of a congenital pigmented mole by a nail, followed by development of the tumour. Operation consisted in removal of primary tumour and axillary metastases. Death occurred within two to three months. *Autopsy*.—Small pigmented metastases were found throughout lungs and liver, an organised thrombus was found almost completely obliterating the portal vein, throughout its entire length from transverse fissure above to the head of the pancreas below. Polylobular cirrhosis was marked. *Histology*.—Structure of metastases in lungs and liver approached to an alveolar type. Dr. Pollock said it was probable that the portal thrombus had been produced by the cirrhosis compressing branches of the portal vein, and thus causing progressive stagnation in main trunk. Metastases in viscera were of such a size as to suggest a dissemination consequent upon opening up of axillary blood spaces during operation.

CARCINOMA OF STOMACH.

Dr. T. T. O'FARRELL showed a stomach removed *post mortem*, which exhibited two ulcers in the fundus and a carcinoma at the pylorus. Free hydrochloric acid had been found in the gastric contents during life.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, MARCH 9TH, 1916.

The President, MAJOR CHARLES J. MACALISTER, in the Chair.

MR. ADAIR DIGHTON related a case of

SARCOMA OF THE NOSE AND NASOPHARYNX.

The tumour was removed under chloroform in September, 1914. The operation performed was a sub-labial-lateral rhinotomy, and in addition a well-shaped section of the upper jaw and palate was removed. The patient was shown. She was healthy, and there had been no recurrence.

The PRESIDENT and Capt. LOGAN discussed the case, and Mr. ADAIR DIGHTON replied.

DR. F. H. BARENDT read an amusing and interesting paper on

THE USE, MISUSE, AND ABUSE OF SOAP.

He described the various pharmacopœial preparations of soap and discussed their relative value. In his opinion far too much soap is used. He concluded with the warning that "soap is a good servant but a bad master."

The PRESIDENT and Major RUSHTON PARKER both joined in the discussion.

Capt. T. R. W. ARMOUR read an interesting paper on

MILITARY ORTHOPÆDICS.

He stated that these cases could be divided into three groups—(1) disabilities occurring in men under training; (2) cases due to wounds or other injuries received on active service. Under the first category were cases of flat feet, hallux rigidus and valgus, pes cavus, internal derangement of the knee, hysterical deformities of hip and spine, sprains and old fractures. These various disabilities were discussed, also the treatment and the prospects of return to duty. Captain Armour prefaced the consideration of deformities acquired on active service by urging the need for attention to the prevention of these deformities, and pointing out how much more might be done for this purpose. He then described a series of deformities produced by fractures of the femur, fractures involving the shoulder, elbow, wrist and hand, injuries to muscles and nerves, and showed several radiographs illustrating the cases. The principles underlying the treatment of each case were discussed and progress described. Reference was made to the value of active exercises carried out under proper supervision as part of the treatment, and the necessity for getting the men to take intelligent interest in their own cases. Several points were brought forward with regard to the adaptability of stumps for the application of artificial limbs.

The paper was discussed by the PRESIDENT, Major RUSHTON PARKER, Mr. NEWBOLT, Mr. JEANS and Capt. LLOYD ROBERTS.

SPECIAL REPORTS.

WAR HONOURS.

DISTINGUISHED SERVICE ORDER.

HIS MAJESTY THE KING has been graciously pleased to approve of the appointment of the undermentioned officer to be Companion of the Distinguished Service Order, in recognition of his gallantry and devotion to duty in the field:—

Qmtr. and Hon. Lt. Edward Lyall, 2nd Northumbrian Field Amb., R.A.M.C., T.F., (attd. 185th Tunneling Co., R.E.). For conspicuous gallantry and devotion to duty. When a large camouflet was blown in by the enemy he hurried through a flooded gallery in the dark, and under heavy fire went for proto apparatus. Finding all the proto apparatus already in use, he hurried on and, although in an exhausted state, descended a shaft without any apparatus, assisted in the rescue of an officer, and then went further, rendered aid to two men, and made a most gallant effort to save two officers.

THE MILITARY CROSS.

The King has been graciously pleased to confer the Military Cross on the following officers, in recognition of their gallantry and devotion to duty in the field:—

Capt. Bernard Grellier, R.A.M.C. (attd. 10th R. Welsh Fus.). For conspicuous gallantry and devotion to duty during operations, when tending the wounded under heavy shell fire. He helped to dig out wounded men who were buried.

Temp. Capt. Leonard Douglas Saunders, R.A.M.C. (attd. 10th Notts and Derby R.). For conspicuous

gallantry and devotion to duty. He tended the wounded under heavy fire, and finally evacuated them all with great skill and care. His clothing was torn by fragments of shell, and he was at work for 48 hours without a rest. This is the third time he has displayed great coolness and devotion to duty.

Temp. Capt. Harry Vere White, M.D., R.A.M.C. (attd. 7th Lincs. R.). For conspicuous gallantry and devotion to duty during operations when tending the wounded. His dressing station was repeatedly hit by shells, and he himself was severely knocked about several times, but for 36 hours he stuck to his work.

Temp. Lt. Reginald Peter Nutcombe Brickland Bluett, R.A.M.C. (attd. 8th Durham L.I., T.F.). For conspicuous gallantry. He tended the wounded under heavy shell fire, and was continuously at work for 20 hours. Through his exertions they were removed to a place of safety, although the aid post was unapproachable owing to the enemy's shell fire.

Temp. Lt. John Alexander Harper, M.B., 52nd Field Amb., R.A.M.C. For conspicuous gallantry when leading stretcher-bearers during operations. On one occasion when three of his bearers were wounded, he went alone, under heavy shell fire, to the aid post.

FRENCH DECORATIONS.

THE LEGION OF HONOUR.

The President of the French Republic has bestowed the decoration of the Legion of Honour, with the approval of his Majesty the King, on the following officers, in recognition of their distinguished service during the campaign:—

GRAND OFFICIER.

Surg.-Gen. Sir Arthur Thomas Sloggett, K.C.B., C.M.G., K.H.S. (substituted for "Croix de Commandeur," the award of which was announced in *Gazette* dated November 8th, 1915.)

CROIX DE GUERRE.

The President of the French Republic has bestowed the decoration "Croix de Guerre" on the following officers, in recognition of their distinguished service during the campaign:—

Lt.-Col. James Mill, M.B., R.A.M.C., T.F.

Capt. John Arthur Cullum, Canadian Army Medical Corps (attd. 28th Canadian Inf. Bn.).

Capt. Eric Dalrymple Gairdner, R.A.M.C., T.F.

Capt. George Herbert Rae Gibson, Canadian Army Medical Corps (attd. Hq., 1st Canadian Divn.).

MENTIONED IN DESPACHES.

The following officer has been mentioned in despatches by Rear-Admiral Sir Dudley De Chair for good services in patrol cruisers:—

Staff Surgeon Robert Bernard Scribner, R.N.

OBITUARY.

DR. EDWARD BENNETT, L.R.C.P., L.R.C.S. EDIN.

DR. EDWARD BENNETT passed away, after a short illness, from pneumonia, at Hillside, Lydbrook, Ross-on-Wye. Dr. Bennett, who qualified L.R.C.P. and S. Edin. in 1900, was the elder son of the late Mr. Edward Augustus Bennett, of Marsdon Hall, Nelson, Lancs. He was educated at Owens College and Edinburgh, and after holding various hospital appointments, started practice at Bottesford, and later removed to Lydbrook. He leaves a wife and young family.

DR. FREDERICK F. GERMAN, L.R.C.P. AND S., CAPT. R.A.M.C., SEAFORTH.

We regret to record the death, which took place on March 27th, at Seaforth, Liverpool, of Captain Frederick Francis German, R.A.M.C., one of the oldest medical practitioners in the district.

The deceased, who was in his fifty-sixth year, studied medicine at Edinburgh, qualifying L.R.C.P. and S. in 1881. He had practised in Seaforth for upwards of thirty-three years.

Dr. German was always greatly interested in military matters, and eighteen years ago held the rank of captain in the old Lancashire Artillery (Volunteers). He resigned his commission in 1907, but continued in the capacity of relieving medical officer at the Seaforth dépôt. Upon the outbreak of war he took

charge of the military hospital at Seaforth, and later was given a temporary captaincy in the Royal Army Medical Corps. He was also surgeon to the Lancashire County Police (Seaforth Division) and the Liverpool Overhead Railway Company, Ltd.

He leaves a widow, daughter, and son, the latter being a staff-sergeant in the Royal Field Artillery.

DR. OLIVER SCANLAN, L.R.C.P. AND S.,
MIDDLESBROUGH.

THE death has occurred very suddenly at Middlesbrough, of Dr. Oliver Scanlan. Dr. Scanlan had been associated in practice with his brother, Dr. A. E. Scanlan, for the past 14 years. Educated at Glasgow, he qualified L.R.C.P. and S.Edin., L.F.P.S.Glasgow in 1901. He was a bachelor.

MEDICAL NEWS IN BRIEF.

Need of Army Doctors.

THE following is the latest official announcement on this important question:—

In order to maintain the supply of medical officers required to meet the needs of the military services, it is urgently necessary in the interests of the civil community no less than of our Armies that *all* qualified medical men not exceeding 45 years of age, irrespective of their circumstances, should without delay enter their names under the enrolment scheme which has been established by the Central Medical War Committee, and has the authorisation of the War Office.

The work of enrolment is carried out by three representative bodies of the medical profession known as the Central Medical War Committee for England and Wales, the Scottish Medical Service Emergency Committee, and the Irish Medical War Committee. It should be understood that enrolment does not mean that the medical man is at once called up for service in the R.A.M.C.; he may never be called up, and in any case will not be called up until the proper time has come for his services to be accepted. The real purpose of the scheme is to secure that those doctors are selected for military purposes who can best be spared at the particular date and from the particular place, with due regard to the needs of the civil population, and to the personal circumstances of the doctor, and to the requirements of the Armies.

To carry out efficiently the comparative process necessary for an equitable distribution of the burden as it affects the medical profession and the civil population, it is evident that *all* doctors of suitable age should have offered themselves for service, so that a proper selection may be made by a body equipped with the requisite information from all parts of the country and thus competent to make the necessary comparisons. The only alternatives are haphazard recruitment and arbitrary demand.

WORK OF THE COMMITTEES.

It is for these reasons that the War Office has officially recognised and now relies upon the Central Medical War Committee and the corresponding Committees in Scotland and Ireland. These Committees include representatives of the Royal Colleges of Physicians and the Royal Colleges of Surgeons, of the universities and medical schools, and of the British Medical Association; and have associated with themselves in their work representatives of the Government Departments mainly concerned.

The Committees have an organisation of representative local committees in all parts of the three countries, from which they obtain local information and advice; and they work in daily contact with the various Government Departments concerned.

Furthermore, for the purpose of considering and advising, through the Central Committee, on cases in England and Wales having such special features as exist, for instance, in regard to the staffs of the Metropolitan hospitals, a Committee of Reference has, with the approval of the War Office, been now

established by the Royal College of Physicians of London and the Royal College of Surgeons of England acting jointly.

University College Hospital.

THE annual meeting of the Corporation of the University College Hospital was held on March 30th at the hospital. Sir Ernest Hatch, who presided, in moving the adoption of the report, said that the number of beds had been increased from 305 to 447. In all 2,000 wounded soldiers had been received as in-patients and over 15,000 as out-patients. The medical staff had been greatly depleted, and a large number of the employees had joined the colours. They had 543 men, including students, and 63 nurses serving at the front. Twenty-eight had been mentioned in Despatches, and one was awarded the V.C. Other distinctions gained included C.B.'s, four C.M.G.'s, four Military Crosses, and one Royal Red Cross. The Roll of Honour showed eleven killed. The extra cost of food, in some cases as much as 50 per cent., had caused considerable concern, and among the many difficulties with which the hospital had to contend was the unprecedented rise which had taken place in the cost of many of the principal chemicals and drugs. These increases were no doubt in some degree due to abnormal medical needs, but in most instances they were attributable to the fact that the drugs had hitherto been solely obtained from Germany.

The Duke of Bedford was unanimously elected President of the Corporation of the Hospital for the ensuing year.

White Labour in the Australian Tropics.

REFERRING to the problem of settling the northern and tropical portion of Australia with "white" labour, Professor Gilruth, the Administrator of the Northern Territory, in a recent report, says: "I am still of the opinion that the climate offers no bar to the proper development by white labour. In certain quarters it has been stated that two or three generations will be required to demonstrate the truth or otherwise of such a contention; but, if no attempts be made voluntarily it is difficult to conceive how the proof will ever be obtained. What can be asserted now is that, given freedom from tropical and other infectious diseases by importation, the evidence available is that the Territory is quite as healthy for white people as any other part of the world. Indeed, it is probably the only part of the continent where men may be seen at any time and all times of the year engaged in hard physical labour in the open air undressed from the waist upwards but for an ordinary felt head-covering. The fear of sunstroke does not exist, and its occurrence in such circumstances appears unknown in the Territory."

The Finsbury Dispensary.

IT has been decided, in view of the war, to abandon the customary biennial festival of the Finsbury Dispensary, which falls due this year, and on which the committee relied for substantial help. It is therefore necessary to obtain by some other means more funds. The Lord Mayor is appealing for contributions to be sent to him at the Mansion House, or to the secretary of the Dispensary, Brewer Street, Goswell Road, E.C.

New Hospital Ship at Basra.

THE hospital ship Sikkim has arrived at Basra. She is a fast, comfortable ship, double-decked, and equipped with electric light and fans, an operating theatre, bath room and accommodating 144 cots.

Health of Leeds School Children.

THE Acting School Medical Officer to the Leeds Education Committee (Dr. Lee Bolton) has prepared an exhaustive report on the work of medical inspection of the school children of the city for the year ended December 31st last. The number of children examined during the year was 17,628, as compared with 14,579 for the previous year, an increase of 3,049.

The percentage of parents who attended the examination of their children was 65.4. When parents attended it was generally found that the necessary

treatment was secured without trouble. There was a slight improvement in the proportion of scholars with satisfactory clothing and footgear, and a decrease in the number returned as uncleanly or verminous. More than 15 per cent. of the children, however, were still attending the schools in a dirty or verminous condition.

Of the 17,628 children examined, 12 per cent. were below normal, and 2.6 per cent. were bad. The number of defects of the nose and throat was 3,885. With the exception of cases of much enlarged tonsils, the percentage of these conditions was lower than that of the previous year. There was a decrease in the number of cases of enlarged glands. There has been a continued improvement in regard to dental caries, for whereas in 1914 25.4 per cent. of the scholars had four or more decayed teeth, in 1915 this figure had dropped to 19.3 per cent. a difference of 6.1 per cent. Poor district schools show the lowest percentage of dental caries, viz.: 57 per cent., whereas in the better district schools the percentage is 62.4, and in the suburban schools 63.7 per cent., while in the Jewish schools it is as high as 74 per cent. The total percentage for all the schools is 61.2 per cent.

Cases of heart affection numbered 167, or 9 per cent. of those examined. There was a great increase in the number of cases of ophthalmia, and the school medical officers reported 1,238 cases of ringworm. Under the head of rickets, the returns indicate 2.3 per cent., against 3.2 last year. Phthisis and suspected phthisis cases have not increased. The dull and backward children were 1 per cent. fewer. 43.3 of the 10,308 children whose eyesight was tested were found to have more or less defective vision. In infectious disease there was a marked decrease.

Ozone "Tired Feeling."

At the March meeting of the Röntgen Society, Dr. W. Harwood Nutt said that several X-ray workers complained of headache and sleepiness after a short time in the X-ray room. In his opinion this was due, not to the ionisation of the atmosphere, but to the generation of ozone, and some experiments he had conducted showed that ozone was actually produced in the neighbourhood of the tube.

Major Wilson, of the Canadian Medical Service, believed that the tired feeling was due to ozone, no matter whether generated from the terminals of the tube or those of the transformer itself.

Heroic Hamilton Doctor's Death.

PARTICULARS are to hand in letters received from the Colonel Commanding and the chaplain as to how Dr. John Wilson, Hamilton, Captain R.A.M.C., who was attached to the 10th Battalion Duke of Wellington's Own, met his death. The Colonel states that at 9.30, on March 9th, a message was received that several men were wounded in a central trench. Captain Wilson at once volunteered to go to their assistance, although it was necessary to cross absolutely open ground swept by the fire of the hostile trenches. He reached the wounded men, bandaged up those who most required it, and was on his way back to shelter when he was fired upon by the Germans from their front line trenches, and a bullet struck him just above the heart. He died in a few minutes. The colonel adds that Captain Wilson by his energy and devotion to duty had earned the appreciation of every man in the battalion, and the Colonel only ten days before had had the pleasure of recommending him for the Military Cross.

Newcastle Infirmary.

THE annual Court of Governors of the Royal Victoria Infirmary, Newcastle, was held on March 25th. The Lord Mayor moved the adoption of the annual report, already published, and remarked that it was the best report ever produced by the institution.

Every page of it told a story, the same story of difficulties that had been encountered and surmounted. There was victory on almost every page.

Time was a great testing force of men and things and institutions. That was true of all times, but it was particularly true of war time. War time was a

great testing force, and it had been testing this institution in every department and in its being.

His Lordship paid tribute to the increased subscriptions of the workmen, which was eloquent, in his opinion, of their confidence in the institution, and, amid loud applause, tendered his congratulations to Sir George Hare Philipson on his association of over half a century with the institution. He had, said his Lordship, "played a straight game, had kept a straight bat, and was 52 not out."

Army Medical Arrangements.

SIR ALFRED KEOGH, speaking in London, on March 29th, said he was, as they knew, in charge of the medical arrangements for the Army in England, France, Mesopotamia, and the Mediterranean, and they could look the public in the face for the first time and say they were doing their best. During the last ten years the Government did make every adequate preparation for the war on the medical side, and that was why, when the present campaign began, they were in a fit state to take on the responsibilities that fell upon them.

Hospital Saturday Fund.

THE forty-second annual meeting of the Hospital Saturday Fund will be held at the Mansion House, on Wednesday, April 12th, at 7.30 p.m. The Lord Mayor will preside, and an address will be given by Sir Alfred Pearce Gould, senior surgeon at the Middlesex Hospital, on "The Effects of the War on Work in Civil Hospitals."

During last year, notwithstanding the many and varied appeals made to the public in connection with the war, the income of the fund steadily progressed, with the result that the total reached £36,809, as compared with £30,130 for the previous year.

Rheumatism at Nuneaton.

AT a meeting of Nuneaton Town Council, on March 29th, Mr. J. H. Whitehouse suggested that samples of water from the different public sources be submitted for analysis, with a view to determining whether there is anything in the water to account for the prevalence of rheumatism in old, young, and middle-aged persons. That disease had never been so prevalent in the district as during the past twelve months.—The suggestion was adopted.

Chemo-Therapy.

WE direct our readers' attention to the announcement that a paper will be read on April 13th, at 5 p.m., at the Royal Society of Medicine, 1, Wimpole Street, W., by Mr. J. E. R. McDonagh, on "The Rationale and Practice of Chemo-Therapy." The paper will probably be followed by a discussion. We expect the paper and discussion to be of exceptional interest, especially as leading chemists are likely to be present.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

OMEGA.—The matter is one to which our attention has been recently directed, and in an early issue we shall deal with it in our editorial columns.

DR. G. T. MABERLEY.—Phenol-phthalein as an aperient is not altogether free from danger. A fatal case has been recorded, following a dose of about five grains.

FURTHER AID FOR SERBIAN WOUNDED.

An additional doctor and seven nurses are to be sent out by the Wounded Allies Relief Committee to strengthen the medical unit already despatched to aid the sick and wounded Serbian soldiers in Corfu.

M.D., M.R.C.P.—It is scarcely to be presumed that German drug preparations after the war will cease to be prescribed altogether by the medical profession in this country. Undoubtedly a protective tariff would materially assist the English manufacturing chemist in this regard. But he would require to be enterprising, more so than in the past, and be prepared to introduce novelties such as would defy competition.

MENS SANA IN CORPORE SANO.—There is much to be said for our correspondent's contention. Unfortunately, however, it is contrary to the Army Regulations, and at present at least, that is as much as can be said on the matter.

UNGALLANT!

BRISTON dispensary has found it inadvisable to appoint a lady practitioner, because of the extraordinary antipathy amongst the poor to lady doctors.

DR. K. J. M. (Rosscarbery).—The Post-Graduate Society to which you refer, ceased to exist several months ago; this is probably the reason why you have received no reply. Regarding your second question, we know of no work on "Tactics and Therapeutics." There are, of course, several reliable textbooks on Therapeutics which might answer your requirements. If we can assist you in your choice please write us further particulars.

EFFECTS OF THE WAR ON CHILDREN.

DR. ROMEO MONTE, chief physician of St. Anne's Hospital, the largest children's hospital in Vienna, is reported to have said, "that the general strength of children, in comparison with normal times before the war, has seriously decreased in consequence of the changed conditions of life."

DR. A. (Edinburgh).—The presence of calculi in the bladder and blood in the urine is an ominous symptom of Hematuria.

SQUILLS AS RAT POISON.

A NEW rat poison, an extract of squills, which has been used by the French Government in the trenches for two or three months, is to be used in a Berwickshire County Council experiment to exterminate rats.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 5TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5.30 p.m.: Prof. A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days, and between 10 am. and 5 p.m. in the Hall of the Museum on the following day.

THURSDAY, APRIL 6TH.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m.: Luncheon Lectures: Dr. F. E. Batten: Acute Polymyelitis. (Lectures II. and III.)

FRIDAY, APRIL 7TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4 p.m.: Dr. L. H. Pegler: Case of Laryngeal Tuberculosis. Mr. E. D. Davis: (1) Report of a Case of Laryngeal Crises, with Abductor Paralysis (Sections of the Brain, Spinal Cord, and Vagus Nerves will be demonstrated); (2) Laryngeal Stenosis following a Bayonet Wound treated by Intubation. Mr. Herbert Tilley: Cases illustrating Results of Intranasal Operation for Chronic Frontal Sinusitis. Dr. James Donelan: Case of Paralysis of Left Vocal Cord in a Young Woman. Dr. Jobson Horne: Two Cases of Suppuration in the Antrum of Highmore due to Uncommon Causes. And other cases.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Special Clinical Evening.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5.30 p.m.: Prof. A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days, and between 10 am. and 5 p.m. in the Hall of the Museum on the following day.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—East Grinstead (Sussex), Newport (Mayo).

Royal Devon and Exeter Hospital, Exeter.—Senior House Surgeon. Salary £250 per annum, with board, apartments, and washing. Applications to Samuel S. Cole, Secretary.

Putney Hospital (Chester Bequest), Lower Common, Putney, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry. Applications to the Hon. Secretary, 198 Upper Richmond Road, Putney, S.W.

St. Bartholomew's Hospital, Rochester, Kent.—Senior Resident House Surgeon. Salary £300 per annum. Applications to Charles Speyer, Secretary.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with board, residence, and washing. Applications to the Secretary.

The Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to the Secretary.

Durham County Hospital.—House Surgeon. Salary £150 per annum, with board and lodging, and war bonus at the rate of £30 a year. Applications to Wm. R. Wilson, Secretary, 683 Saddle Street, Durham.

Norfolk and Norwich Hospital, Norwich.—House Physician. Salary £400 per annum, with board, residence, and laundry. Applications to Frank Inch, Secretary.

Westmorland Consumption Sanatorium and Home, Grange-over-Sands.—Second Assistant. Salary £200 per annum, with apartments, board, and laundry. Applications to C. F. Walker, M.D.Lond., D.P.H.Man., Medical Superintendent, Tuberculosis Officer for Westmorland.

Chestonfield and North Derbyshire Hospital.—Second House Surgeon. Salary £150 per annum, with board, apartments, and laundry. Applications to the Secretary.

Appointments.

PRICE, C., M.R.C.S., L.R.C.P., Resident Medical Superintendent of the Children's Infirmary, Cleveland Street, W.

ROBERTS, H. S. W., L.R.C.P., and S.Edin., Certifying Factory Surgeon for the Ballindalloch District, co. Banff.

LAM, PING WING, M.B., Ch.B.Edin., has been appointed Resident Medical Officer to the Leicester Board of Guardians.

PEACHELL, GEORGE ERNEST, M.D., B.S.Lond., L.R.C.P., M.R.C.S., has been appointed Medical Superintendent at the Dorset County Asylum.

Births.

BIGGER.—On April 2nd, at Cairo, the wife of W. K. Bigger, Lieut., R.A.M.C. (*née* Dorothy Vigers), of a son.

CLARKE.—On March 28th, the wife of Lieut. H. H. Clarke, R.A.M.C., of a daughter.

HERDMAN-NEWTON.—On March 30th, at Walker Vicarage, Newcastle, the wife of R. H. Herdman-Newton, Surgeon, R.N., of a daughter.

IREDELL.—On April 2nd, at 7 Cumberland Terrace, Regent's Park, the wife of Dr. C. E. Iredell, of a son.

PARTRIDGE.—On March 28th, the wife of Victor S. Partridge, L.R.C.P.Lond., M.R.C.S., of 131 Coldharbour Lane, S.E., Temp. Lieut., R.A.M.C., of a daughter.

ROBINSON.—On March 25th, at The Cottage, Blundellsands, the wife of G. Burton Robinson, Captain, R.A.M.C. (T.F.), West Lancs Field Ambulance, of a son.

SPARROW.—On March 29th, at 24 Essex Road, Watford, the wife of E. C. Sparrow, M.B., temporary lieutenant, R.A.M.C., of a daughter.

WORTH.—On March 24th, at Middlesex County Asylum, Wandsworth Common, S.W., the wife of Dr. R. Worth, of a son (still-born).

Marriages.

BENTLEY—SCOTT.—On March 28th, at St. Mary's, Kennington, Kent, Richard John Bentley, M.B., B.S.Lond., of Northend, Ashford, to Ida Mildred, eldest daughter of Major H. W. Scott, the Lancs Fusiliers, of Temple House, Kennington.

DEVINE—MILES.—On April 1st, at Our Lady and St. Joseph's, Poplar, Major J. A. Devine, D.S.O., R.A.M.C., of Winnipeg, Canada, to Mary Hilda, only daughter of the late Henry Miles, of Liverpool, and of Mrs. Miles, of 99 Cambridge road, Southport.

GUINNESS—CHARRIOL.—On March 30th, quietly, at St. Mary of the Angels, Bayswater, Alexander F. Grattan Guinness, R.A.M.C., third son of the late Dr. H. Grattan Guinness and Mrs. Guinness, of "Mount Hermon," Sydenham, and Inez Annita Crauivud Charriol, eldest daughter of the late Monsieur et Madame Pierre Charriol.

HUNTER—CAPE.—On March 31st, in London, by licence, Capt. Ronald Nelson Hunter, R.A.M.C., eldest son of Mr. and Mrs. C. D. Hunter, of Buckhurst Hill, to Isabella, eldest daughter of Mr. and Mrs. J. Wilson Cape, of Carlisle.

WAUGH—PICKERSGILL.—On March 27th, at Christ Church, Sunderland, William Grant Waugh, Captain, R.A.M.C., eldest son of Percival Waugh, 21 Cluny Gardens, Edinburgh, to Enid, only daughter of the late Charles Pickersgill and of Mrs. Pickersgill, The Elms North, Sunderland.

Deaths.

LAMBERT.—On March 29th, died on active service, Major F. C. Lambert, R.A.M.C., eldest son of Lt. Col. Lambert (late), R.M. Artillery, of Lyston, Branksome Park, Bournemouth, aged 37.

LEON.—On March 30th, at 23 Grove Road, Southsea, of cerebrospinal meningitis, John Temple Leon, M.D.Lond., Captain, R.A.M.C. (T.), aged 50.

MACPHERSON.—On March 31st, at Barrogill, Bothwell, N.B., William Grant Macpherson, M.B., elder son of the late Rev. James Macpherson, of Canisbay, N.B., in his 54th year.

OWEN.—On April 2nd, suddenly, Samuel Walshe Owen, L.R.C.P., M.R.C.S., L.S.A., of 188 Holland Road, Kensington, younger son of the late Major T. R. I. Owen, of the Bengal Staff Corps, in his 66th year.

PRICE.—On March 29th, at Hoopers Hill House, Margate, William Price, M.D., last surviving son of David Price, M.D., of Margate, aged 79 years.

SALTER.—On March 28th, very suddenly, at Royal Berks Hospital, Reading, Stephen Thomas Salter, M.A., M.B., son of the late Stephen Salter, of Woburn Place, and Watford, aged 57.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, APRIL 12, 1916.

No. 15.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

FROM the point of view of the Medical Profession, Mr. McKenna's **The Budget.** second Budget must be considered a disappointing one. It is equally disappointing in what it does, and in what it does not do. That existing taxes would be raised and new taxes imposed was, of course, inevitable, but it would be impossible to admit that in this case the extra burdens have been placed on the shoulders best able to carry them; nor can it be said that the important question of the public health has been given the careful attention which a far-seeing statesmanship would have assigned to it. It is becoming increasingly evident that legislative enactments of every kind trench on the domain of the sanitarian, and it is the duty of members of the profession to bring this fact out whenever occasion serves. Budgets, especially, are very potent factors for good or evil in this direction.

Motor-Cars. LEAVING aside the fact that, in raising the income-tax, the present proposals do not draw a sufficient distinction between earned and unearned incomes—a matter upon which a hygienist might have much to say—the new taxes offer abundant material for criticism from the point of view I am considering. Taking the relatively innocent-looking tax on motor-cars, it must be obvious to anyone that a distinction should be drawn between a car used purely for pleasure and one which is used solely for business or professional purposes. That the opulent ladies who, on their way from one smart charity gathering to another, rolls-royce about the London streets, covered with pekinese, should contribute on anything approaching the same level as, say, a busy practitioner, is a ridiculous anomaly. And the busy practitioner is by no means the only person who requires consideration under this head. There are other kinds of work almost as necessary to the community as doctoring, in which motor-cars have become essential. In this matter a very hard and fast line should be drawn between necessities and luxuries. Mr. Goschen, when Chancellor of the Exchequer, drew such a line in the matter of horses, and Mr. McKenna could do it in the matter of motors.

Travel.

THE new tax on railway tickets is by no means free from objection. With the "back to the land" campaign in full cry; with sanitarians, Dr. Brend at their head, insisting upon the importance of pure air in the saving of infant life; and with doctors daily and increasingly prescribing change from town to country or seaside in convalescence and threatening disease, here comes the Government with a measure which will certainly do a great deal to discourage travelling, especially systematic, season-ticket travelling, with the result that people will be herded into the towns. The "back to the land" campaign will die of inanition and His Majesty's lieges of tubercle; British health resorts will suffer, convalescence from illness will be prolonged, and threatening disease will progress to its devastating conclusion. Travel, even for pleasure, is much more a function of health than the mere politician seems to realise.

Mineral Waters.

THE cynic might find something to say on the fact that, whereas spirits, wines and beers are not touched, mineral waters are boldly attacked. This is presumably an invitation to the teetotaler to "do his bit." But, apart from the fact that there is nothing whatever to show that the teetotaler is in any degree a slacker or shirker, either militarily or financially—indeed, the facts point in precisely the opposite direction—the tax catches a good many beside the teetotaler. It catches the constipated, who find relief from the sulphated waters; it catches the people, and they are many, who cannot drink chalky water with impunity, and forces them to consume the hard water with which London and many other places are served. Much energy and eloquence, and a few shining examples, have placed before us the virtues of teetotalism in war-time, and now comes the Chancellor with a heavy back-hander for those who, by much tribulation, have learnt to prefer Malvern Water to someone's XXX. Let us hope that such people will be able to appreciate the humour of the situation.

Sugar and Coffee.

THE extra taxes to be levied on sugar and coffee must seem to the medical man wholly indefensible. Such an important article of food as sugar, which, owing to the general dislocation of

pre-war conditions, has already risen enormously in price, ought not to suffer a further burden until other sources of revenue have been tapped. Sugar is one of the chief food-stuffs of the poor, especially of the children of the poor, and its supply to the lower classes ought not to be curtailed by taxation unless the reasons for so doing are really overwhelming; and this they obviously cannot be. The further taxation of sugar is almost as serious a matter as the taxation of bread. Nor does there seem to be any adequate excuse for the further taxation of coffee. Coffee is an agreeable, a harmless, and in many cases a very desirable stimulant, and it is not right that it should be made to contribute any more while the alcoholic stimulants remain untouched.

Patent Medicines.

WHEN attacking the morally and medicinally innocent mineral water group, it is a pity that Mr. McKenna did not carry the excellent principle which he established last year still further along its beneficent course, by increasing the tax on proprietary medicines. These commodities yield enormous profits to their proprietors, while conferring no commensurate benefits upon the public. That some of them are harmless is quite true, but when they are harmless they are frequently inert. Some of them—as, for example, the purgatives—are beneficial, but even in the case of these the buyer pays a sum for his purgation which is about 75 per cent. above the ordinary market value of the active ingredient. All of them, however, are by no means harmless, and their taxation, even out of existence, would materially contribute to the well-being of the community. A writer in the *Westminster Gazette* says: "A great reform has been missed in the omission to increase considerably the duties on patent medicines, at the same time using the opportunity to insist on the labels bearing a description of the composition of the article, the proportion of the ingredients, and the amount of the dose." I cordially agree.

Dogs

BUT the most regrettable omission in the present Budget proposals is the failure to increase the dog licence. The vast majority of dogs are pure luxuries, whose owners can well afford to pay a vastly increased price for the pleasure which these quadrupeds undoubtedly confer. But they are not only luxuries; they are extravagancies. The amount of food eminently fitted for human consumption which is daily and daintily sacrificed at this particular shrine must represent an enormous sum of money—and this at a time when everyone is being urged to practise economy in every possible direction. Not long ago, at an hotel at the seaside, I counted six elderly moth-eaten ladies who left the dining-room with plates full of food, collected during the table d'hôte dinner, which they were taking to their dogs upstairs. On economical grounds alone it is surely more just to tax this sort of thing than to raise the price of sugar or coffee.

and Disease

BUT considerations of economy in food are by no means the most convincing reasons which can be urged in favour of the deterrent taxation of dogs, especially in towns. That there are such beings as human "carriers" of typhoid fever is now well known, and there is not a shadow of a doubt that dogs may be "carriers," not only of typhoid, but of other diseases. The greatest possible care is rightly given to the proper disposal of human excrement. Millions of pounds have been spent on main drainage schemes, and the public official's solicitude for the sanitary condition of the individual house amounts to an inquisition. That is exactly as it should be, but every standard of true hygiene is being clothed with derision so long as dogs remain the licensed libertines of the streets.

in Towns.

SETTING aside the extra cost of scavenging which they entail upon the public official, it must be within the disgusting experience of everyone that much of the scavenging is done both involuntarily and inefficiently by the boots of the passers-by; with immediate results into the details of which it is not necessary to enter. The remote results are, of course, impossible to trace, but it requires very little imagination to find in them a very large number of those cases of so-called sporadic disease which baffle the most careful search into their origins. I have on several occasions pointed out the danger to the public health which the present dog-licence encourages, and I find that during the last few weeks several letters have appeared in the lay press insisting upon the same obvious truth. It is a great disappointment to all those who have the well-being of the community at heart that Mr. McKenna has turned a deaf ear to the suggestions which have been made to him on this subject. If the whole truth were known, it would almost certainly appear that one of the most potent factors in raising the death-rate of children was the practice of keeping canine pets.

Cats.

THE proposal which has been made that cats should be taxed or licensed is based on the belief that, in common with dogs, these domestic animals are carriers and propagators of disease germs. That may or may not be the case; it is at any rate certain that the cat has a good deal more to the credit side of his account than can on the most liberal estimate be allowed to the dog. Professor Robert Wallace, of Edinburgh, points out that but for cats the country would be absolutely overrun with rats and mice, with the almost certain result that bubonic plague would become an ever-present scourge. Moreover, even as things now are, rats and mice are computed to destroy foodstuffs to the annual value of twenty millions sterling, a figure which would be very largely increased if people were deterred by taxation from keeping cats. Professor Wallace pleads for more care in breeding the right type of cat. For the lady basket cat a good ratter should be substituted, and he should be encouraged to find his own food.

Foresight. The callousness of legislators about most questions of public health is a by-word among sanitarians. At the present moment solicitude for the future of the race is everywhere uppermost, except in Parliament. At Westminster if you dare to look more than three years ahead, you are voted a visionary and a bore. To propound a question which will not come to fruition for twenty years is to stamp yourself as academic and unpractical; and so our lawyer legislators continue to treat symptoms with hastily improvised emergency measures instead of studying to correct the original dyscrasia. An article such as that which Dr. Brend contributed to the "Nineteenth Century" for March, to which I referred last week, is likely to fall on stony ground, for the land is under the sway of the opportunist, unimaginative lawyer-politician. I do not pretend that the problem which Dr. Brend exposes with so much ability is one which is easy of solution, but I maintain that it is one for which everyone with any claim to the title of statesman should at once set himself to find a solution.

Town and Country. The problem is this. From the points of view both of health and of economics it is very desirable that people should go back to the land. Instead of doing this, however, they continue to swarm into the towns, and so far as one can see at present, unless something is done to render the land more attractive, the living call of the towns will continue in increasing measure to prevail. The desire for "more life and fuller" is a very intense one. Amongst country people it may take a form no more clearly defined than a "blind desire," but for the man who has once tasted it, the gregarious life of the city will always hold compensations for the loss of what the country alone can offer in healthfulness and peacefulness. A short life and a merry one is not a mere adage. The saying represents a fundamental preference which is innate in the majority of both men and women, and they will take the risks of conditions which are said to impose the shortness, provided they can be assured, if not of merriment itself, then certainly of the possibility of escaping from boredom.

Back to the Land. It seems, therefore, that the campaign to return the people to the land is foredoomed to failure. The attractions of the towns must be regarded as a ground fact, from which there is at present no escape, and a real foresight would look this fact in the face and seek to mitigate what it cannot prevent, namely, the evil effects upon health generally and infant mortality in particular which town conditions at present impose. We have already secured sound drainage and pure water, and the logical outcome of Dr. Brend's paper is that we should at once set about promoting pure air. Much has already been done in this direction. Of town planning, garden cities, and the like, Dr. Brend writes with unqualified approval; but much more remains to be done. The dust from the whirling motor and the smoke from

the domestic chimney are still with us. Asphalted and paving of the main streets have tended to lessen the former, and the nuisance of the latter has been much abated since the improvement in gas fires and the introduction of electric heating. These should be encouraged; but there are other things which ought to be attempted.

Central Heating.

What is known on the Continent as central heating is almost unknown in this country. It is, of course, installed in many modern mansions, both town and country, but it has made little or no progress in the case of moderate-sized houses, and still less in groups of small houses. And yet, if builders were to be urged thereto by the local authorities it would be easy for them to instal one central heating-furnace for each block of houses. Such an arrangement would not only reduce the cost of warming an individual house, but the warming would be much more efficient, and there would be no smoke. Such systems could be applied to existing blocks, and, in the case of moderate sized houses, they would probably be very much appreciated. The obstacle is the initial cost of installation, and it is here that the local authority could intervene with great effect. If the system were worked by the authority the undertaking would very soon become a paying concern. The great obstacle to any such scheme is the senseless tradition that an Englishman's house is his castle. In so far as it is his castle, the ordinary Englishman's house is a very ill-managed castle, to the dungeons of which he is careful to consign both his thrift and his health.

Upper Air-Passages.

Another direction in which the well-being of town dwellers could be more carefully safeguarded than it is at present is by paying very special attention to the upper air-passages in young children. Considerable improvements have already been effected in this matter, but a cursory glance through the pages of the new edition of Sir St. Clair Thomson's book have impressed upon me the necessity for doing a great deal more. But of this, more anon.

SINAPIS.

CURRENT TOPICS.

The Troublesome Useless Uterus.

In a recent number of the *New York Medical Journal*, Dr. Ernest Gallant has laid down some very definite rules for the recognition and treatment of what he terms "the troublesome useless uterus." As to treatment, there is no question: it is always to be hysterectomy. Besides such obvious causes as cancer and multiple fibroids, he considers that many uteri are rendered troublesome and useless by the presence of pus tubes, adhesions, perforation, or syphilis. Lastly, he includes a series of cases showing a number of allied symptoms due for the most part to the partial prolapse of a heavy, sub-involved uterus, the seat of endometritis. Hysterectomy is a drastic alternative to the use of a pessary, but the author of the paper finds it as a rule more satisfactory. To many gynaecologists his statement that it is unwise to amputate the cervix of a partially descended uterus will come as a distinct surprise. Hysterectomy is

not generally considered an advisable procedure for the cure of prolapse. The cystocele and rectocele, which have caused perhaps the most unpleasant symptoms, still remain and tend to become further exaggerated. Dr. Gallant having proved this fact, advocates in every case complicated by these conditions a complete or partial colpectomy. Some of us are less heroic in our treatment, and even flatter ourselves that we can get good results from our favourite combination of the various operations which come under the heading of vaginal repair, together with suspension or fixation of the fundus uteri. Nevertheless, this paper is of great interest. Some 30 cases are fully described, and the writer has, on the whole, no cause to be dissatisfied with his results. The most obvious criticism is to propound the question whether the troubles of those eighteen women upon whom hysterectomy was performed before the menopause could have been relieved and their uteri at the same time restored to utility. Dr. Gallant is convinced that the answer to this question is in the negative. Some gynaecologists will find it hard to agree with him.

Reminders.

A FEW hints from Baltimore may be timely in the matter of hospital administration and efficiency. The cost per head is no index to the quality of work done. Attention is to be concentrated upon the patient, and in this matter are to be considered courteous attention, even to the poorest, prompt and skilful medical attendance, careful and sympathetic nursing, to be combined with complete study and accurate record of clinical findings, not only in relation to the particular case *per se*, but also with reference to the disease as an abstract study. Finally, discharge of the patient, not prematurely—with full directions for his domestic procedure—and a recollection of him for future purposes as an individual human being—and not a mere cipher or number in a register. Our readers may smile and wonder at such a list of accepted platitudes. But there will be many of us who may experience, not serious self-accusation, but some searchings of the heart for shadows. There may have been, not negligence, but postponements—irritability rather than incivility, a tendency to dwell upon a case rather as a specimen of interest than as a human brother or sister, of the same subtle and complex structure as ourselves.

French Infantile Mortality.

PROFESSOR A. PINARD reports that infantile mortality has been lower in France during the present war than ever before, whilst the health of the children has been better. During the first year of the war the death-rate of mothers after confinement was lessened; the proportion of still-born children, instead of increasing, as had always been the case during previous wars, diminished; the proportion of children placed in foundling hospitals at birth also decreased. The number of prematurely born children was reduced. The average weight of children at birth increased.

Prof. Pinard asserts that never have so fine and healthy children been seen in Paris as now, and gives as the reason that they have never been better cared for. This justified completely the measures taken at the beginning of the war for protecting mothers before and after child-birth; for encouraging and assisting mothers to nurse their own children; and, when necessary, for supplying sterilised milk obtained from cows in a special herd—the property of, and under the supervision of the City of Paris.

Professor Pinard concludes with a warning note.

In the last few months infantile mortality, although still below that of 1913, has risen above that of the first year of the war. He attributes this to the fact that trade is being gradually resumed, while the number of male workers has scarcely increased, so that mothers have been tempted to work under conditions less favourable to their offspring, and also to take up harder kinds of work.

Nerve Injuries in the War.

THE Société de Neurologie has just concluded a session in Paris, which was attended by representatives from all the military centres for neurological work in France. The British War Office sent Col. Aldren Turner, and Colonels Gordon Holmes and Percy Sargent represented the neurological centre in Boulogne. Dr. Henry Head was present on behalf of the National Health Commissioners. The Italian Government also sent a representative.

The whole session was devoted to a series of discussions regarding the many nervous affections, organic and functional, produced by the war. Each discussion ended in the formulation of a number of practical conclusions. M. Pierre Marie emphasised the difficulty in determining what course to pursue in regard to soldiers wounded in the head who had suffered no grave injury of the brain. Many speakers pointed out that these men were "unstable," and might become a source of weakness at the front. Their memory was often weakened, especially for orders. They were liable to develop headache and become sleepless, also easily tired. The conclusion was that these men should be watched on duty for three months at least before returning to the firing line.

M. Pabinski showed some remarkable cases where a purely functional paralysis had led to changes in the tissues of the affected limb which could not be removed by suggestion. He earnestly implored that these patients should be sent in an early stage to the nearest neurological centre in order to give the best chance of a cure.

M. Vincent described from personal experience at the front the nervous conditions arising from the discharge of large quantities of high explosives.

All the questions discussed bore a direct relation to the war. Many members returned to their posts at the front on the close of the last sitting.

A Step Further.

WE have already drawn attention to the supervision of child activities generally practised in the New World. The clinical net is now to be cast wider to enclose the parents. There is nothing new in the inclusion of gross pathological antecedents, such as alcohol, insanity, or syphilis, but one is almost alarmed at the minute inquiry into the temperament and personality of forebears. Such common property as tendency to mental depression, super-sensitiveness (so-called), or irritability, form links in a cumulative process which eventually terminates in the production of an obviously impossible individual—even the dementia praecox. The psycho-analyst appears satisfied, and there the matter would seem to end. What practical and prophylactic conclusions are to be drawn is not made very clear. Yet if the progressive danger in succeeding generations is really so great, one is tempted to think that in the case of temperamentally unstable individuals marriage should be discouraged. This cannot reasonably be done unless the growing practice of voluntarily seeking medical advice, prior to matrimony, becomes universal, and is to comprise also mental analysis by an expert. Finally, there is the extreme probability of disregard of professional recommendations. We are slow to disparage study

along these lines of supreme importance, yet it is possible that they are tending to partake rather of the nature of intellectual ends than of therapeutic means. Again, with these frailties so generally diffused, elimination of them from amongst us is a stupendous task. Moreover, some of the greatest and most useful figures in history were pronouncedly neurotic, and the secret probably lies in the judicious devising of means and channels whereby these aberrations find harmless or even useful expression.

The College of Nursing.

WE are glad to see that the Society for State Registration of Trained Nurses has taken the step of appointing a Protection Sub-Committee to safeguard the rights and privileges at present enjoyed by certificated nurses as against the dangers threatened to the nursing profession by the proposed establishment of a College of Nursing. It is a misfortune that such a committee was not in existence two years ago. If it were, it might have been able to prevent some of the disasters that have come on the nursing profession since the beginning of the war. No one would have thought, however, two years ago that in a time of national demand for trained nursing, the authorities would have permitted trained nurses to be jostled out of their legitimate employment by the intrusion of a crowd of amateurs, and that the salaries of trained nurses should be depressed by the competition of untrained persons. However, these things have come to pass, and they have been brought about mainly by the influence of a body whose head is the promoter of the College of Nursing. *Timeo Danaos et dona ferentes.* It will not add to the confidence of nurses in the proposed college that Mr. Arthur Stanley has stated that it is his wish that the Council of the College should supervise the education of "V.A.D.s."

Modern Treatment of Penetrating Chest Wounds.

DR. PERREAU, of Paris, has given his experience in the treatment of penetrating chest wounds. He states that in the course of seven months he treated 117 cases of chest wounds, 67 of which were penetrating. On account of the frequency of complications (embolism, pleural effusion, subcutaneous emphysema, broncho-pneumonia, hæmorrhage of the lung) it is very important to apply as early as possible a form of treatment which will prevent these appearing, or at any rate considerably diminish their frequency. His treatment consists of *immediate, absolute and prolonged* immobilisation. During the first two days the patients were put on a purely water diet, and enjoined to avoid all movements and not to speak. From the third to the fourth day a more liberal diet was gradually allowed, the patients being spoon-fed by the orderlies. During the first four or five days Dr. Perreau injected every day 10cc. of camphorated oil.

Military Service and the Position of Chemists.

A CENSUS of the dispensing staffs of chemists and druggists is being taken throughout Scotland to enable the military authorities to judge how many, if any, men can be spared from present staffs for military service. Already the Glasgow census returns are in the hands of the Clerk to the Burgh Insurance Committee, and those of the Central District of Scotland are on the eve of completion. It is quite current talk that the chemists have gone to military service in very large numbers, and the

fear is that the limit has already been reached; the number left are sufficient, and no more than sufficient, to look after the interests of the population at home. But the census will give figures which will help to clear up the point as to whether or not there is general scarcity or local scarcity of chemists, and proceedings can be taken if needed. The Pharmaceutical Society, with its strong element of business power, can be trusted to represent the position of their members with force and justice.

Mental Symptoms in Cerebro-Spinal Meningitis.

DRS. ESCHBACH AND LACANE communicated to the Society of Medicine an account of two cases of cerebro-spinal meningitis which presented all the appearances of mental cases. The psychological symptoms due to the action of the meningeal infection on the cerebral cortex preceded the classic symptoms of meningitis. One case presented mental confusion and the other melancholic depression, and it is rather interesting to be able to assign to these mental states such a clear and precise organic cause as cerebro-spinal meningitis.

PERSONAL.

THE KING has been graciously pleased to appoint Charles Yelverton Pearson, Esq., M.D., F.R.C.S., to be one of His Majesty's Honorary Surgeons in Ireland, in the room of Sir Charles Bent Ball, Bart., M.D., deceased.

SIR ALMROTH WRIGHT has been elected a foreign associate of the French Academy of Medicine.

MR. SAMUEL WHITBREAD, M.P. Bedford, 1852-1895, left £2,500 each to the Bedford County Hospital and the Middlesex Hospital Ward for Cancer.

DR. BARCLAY S. BARON, Lord Mayor, and Dr. Colston Wintle, Chairman of the Health Committee, have been placed on the Commission of the Peace for the city of Bristol.

MR. S. H. RENSCHAW has intimated that he will give £2,000 to Bury Infirmary to endow two beds, one in memory of his wife and one in memory of his son, Lieutenant Alfred Renschaw, 5th Lancashire Fusiliers (T.F.), who was killed in action in the Dardanelles.

DR. R. B. MITCHELL, who has been Medical Superintendent of the Midlothian and Peebles Asylum since 1888, having retired on pension as from May 28th next, the District Board of Control at its last meeting resolved to place on record its appreciation of the excellent work he had done during his 28 years of service, and has appointed Dr. James H. C. Orr, at present his assistant, to succeed him.

THE following gentlemen have consented to act as the consulting staff at the "Star and Garter" Home for totally disabled soldiers and sailors:—Consulting Physician, Sir David Ferrier, F.R.S.; Visiting Physician, Dr. S. A. Kinnier Wilson, M.D., F.R.C.P.; Consulting Surgeon, Mr. Wilfred Trotter, M.S., F.R.C.S.; Consulting Urologist, Mr. J. Thomson Walker, M.B., F.R.C.S.; Consulting Ophthalmic Surgeon, Dr. A. C. Hudson, M.D., F.R.C.S.; Honorary Dentist, Mr. Donald Campbell; Honorary Surgeon, Mr. Harry Wade, M.R.C.S., L.R.C.P.

CLINICAL LECTURE

ON

CANCER OF THE BREAST.

By G. P. NEWBOLT, F.R.C.S.Eng.,

Honorary Surgeon, Royal Southern Hospital; Lecturer and Examiner in Clinical Surgery,
University of Liverpool.

It is evident that the public do not yet realise the importance of early operation in cases of cancer of the breast, and for this they can hardly be blamed inasmuch as many medical men still give their patients bad advice in these cases. Quite recently I saw a lady with a lump in her breast which was of stony hardness and evidently malignant. She had consulted a doctor in town practice, five years before, when the lump first appeared, and his advice to her was that she need not trouble about it for ten years. I removed the growth together with the infected axillary glands, but how much better it would have been if the tumour had been removed when first it was noticed. A fortnight ago, I saw a woman upon whom an operation had been performed for cancer of the breast, and here the growth was recurring in the scar. In addition there were two nodules in the breast. In this case, a local removal had been done with dire result. The doctor, however, is not always to blame, as very often the patient cannot persuade herself to submit to the necessary mutilation. Of this, the following extract, taken from a doctor's letter, is an example. "Miss W. has had breast trouble, apparently, starting as a mastitis or innocent growth years ago. Now, however, it is malignant with enlarged glands in the axilla and it is developing into "cancer en cuirasse." Fifteen years ago, a lady asked me to remove a growth from her right breast, and as it was evidently malignant I advised complete removal of the growth and breast. To this she would not consent, and eventually I removed the tumour with a portion of the breast, thinking this was better than doing nothing at all. She remained well for ten years and then a growth appeared in her left breast which I removed, but it was of a cystic nature and growing rapidly so that the prognosis was bad. Now although one has seen some hundreds of cases of cancer of the breast in all stages in a certain number a correct diagnosis is impossible until the growth has been examined after removal. For example, six months ago, a single woman aged 30 consulted me about her breast, which was tender, indurated and enlarged. There was œdema and slight redness but no apparent reason for her getting an abscess. Her axillary glands were enlarged. She was taken into hospital and her breast was fomented for a week. As there was no improvement I made a section into the breast. It was not like a carcinoma on examination, but yellowish patches were dotted over the section and they closely resembled tubercle. I dissected out the axilla and removed the breast. The glands removed were large and adherent, and I felt sure that I was dealing with tubercle. Microscopically, the main growth was inflammatory, but at one spot cancer cells were present. At her age the combination of inflammatory trouble and cancer made the prognosis exceedingly unfavourable, and so it has turned out, for nodules have appeared in the scar, and the glands above the clavicle are becoming affected. Again, in cases of chronic interstitial

mastitis it is impossible to say when the cancerous process supervenes. In one instance in which I removed the breast for this trouble, after numerous sections had been made a focus of malignancy was discovered.

It may be said that a fresh section at the time of operation will confirm the diagnosis, and the answer is: Yes, as a rule it does, but there are exceptions, and in either of the cases I have quoted the growth might easily have escaped observation during a hurried examination. One of the most difficult things to diagnose from cancer is a thick-walled cyst situated deeply in a well-developed breast. If it is absolutely necessary to make a diagnosis on the spot (and sometimes it is), an exploring trochar is the most certain method, for it is difficult, if not impossible, to get fluctuation in a cyst deeply imbedded in breast tissue. Another instance in which it behoves one to be wary is the cyst in a middle-aged woman, for its wall may be infiltrated with malignant disease of the worst type. Those I have seen have been in well-developed breasts in women otherwise healthy, and the disease in one case proved fatal in eighteen months after it was first noticed. Whenever there is any doubt, it is wise to cut into the growth at the time of operation, for one does not like to run the risk of removing a breast for a chronic abscess, and only the other day I opened in this way a small chronic abscess with a thick wall in the breast of a young unmarried woman. It closely resembled a solid growth, but it was slightly tender. How constantly women tell the surgeon that the tumour is not painful, and the popular superstition still exists that it cannot be cancer because it is not painful. In my experience, cancer of the breast is rarely painful. Retraction of the nipple is by no means always present, and in quite a number of cases I have pointed out to my house surgeons the absence of this symptom in fairly well advanced cases. Only to-day I demonstrated to some students a case in which the growth was the size of an orange, and yet the nipple was quite prominent, but in nearly all of these cases there was dimpling of the skin over the growth. Cases in which the breast is well developed and the growth small need very careful examination, or the growth may be overlooked. In these cases the proximity of the cancer to the pectoral fascia leads to an early infection of the axillary glands. In a group of five cases, recently operated upon, in only one was there retraction of the nipple, in a second the nipple had never been prominent, and in the remaining three the nipple was normal, but in all five the skin was dimpled. The operation for removal of a cancer of the breast in skilled hands is practically without mortality, and as far as the operation itself goes is most satisfactory. The majority of the patients are able to get up at the end of a fortnight and speedily regain the use of their arms. The drainage of the axilla has revolutionised the operation, and with ordinary care primary union may always be expected. Of course, there are cases in which, owing to free

removal of skin, some tension results, but this is usually to be avoided. The most important step is the careful dissection of the axilla. I usually content myself with the free removal of that portion of the pectoral muscle which lies under the breast itself, but sometimes remove all but the clavicular portion of the muscle. All vessels are picked up at once, and the denuded portion of the chest wall is covered with gauze dipped in warm saline solution. Directly the breast is removed the growth is carefully examined in order to estimate its extent, so that if necessary the adjacent structures may be more widely removed. Of course, a fresh knife and a change of gloves is essential. After operation, the arm is left as free as possible, and the patient encouraged to use it a few days later.

Are there cases which it is not wise to operate upon? Certainly there are. In cases now rarely seen in which ulceration is present with widely infected glands, the foul mass may be cleared, but only on the understanding that it is not a curative process, but carried out in order to make the patient more comfortable. The cases in which the skin is infiltrated "cancer en cuirasse" are hopeless and better left untouched. X-ray treatment will in many cases alleviate pain if present. In my opinion, where the supra-clavicular glands are involved the outlook is extremely grave; perhaps life may be prolonged by operation, but the prospect of cure is remote. Pain in the spine and in the hip should be carefully investigated, for it is useless to remove the breast when the patient has secondary deposits elsewhere. In those who die soon after operation for advanced disease in the breast, it is often mediastinal or lung trouble which proves fatal.

What is the prognosis in cases of cancer of the breast? This usually depends upon the stage at which removal is carried out, and also upon the age of the patient. There is no doubt in my mind that the prognosis in young and otherwise healthy people is very bad indeed, and one's best results are in women over fifty years of age. In male cases the outlook is extremely poor. If one gets the case early, and when the growth is the size of a hazel nut, or when one has to deal with a chronic mastitis becoming malignant, it is good. I remember the case of a lady operated upon in the year 1904 for a small growth on the inner side of the breast, in which there is no sign of recurrence so far. As the tumour progresses in size the glands become involved, and though one may clear the axilla, there is most probably extension to the glands above the clavicle or into the mediastinum. Many cases die some time after operation of mediastinal glandular infection. Another spot where secondary deposit appears is in the upper portion of the sternum, where a distinct prominence may form. The other breast not infrequently becomes involved, and I have recently amputated the left breast of a lady for cancer whose right breast I successfully removed six years ago for the same disease. The points one has to remember are early diagnosis by removal and examination of all breast tumours, and, if malignant, a wide removal of the growth and a careful dissection of the axilla. Albuminuria and sugar do not prevent this operation being successfully performed, and a good prognosis is probable in the majority of instances.

DR. ARTHUR RICHARD BARNES, M.D., of Green Trees, Merstham, formerly of Boreham, near Hastings, left £17,436.

MR. JOHN EDWIN NIXON, Senior Fellow of King's College, Cambridge, whose estate is valued at £13,040, bequeathed £100 each to King Edward VII. Hospital, Windsor, and Addenbrooke's Hospital, Cambridge.

ORIGINAL PAPERS.

SURGICAL "DON'TS."

(THIRD SERIES.)

By C. HAMILTON WHITEFORD, M.R.C.S.,
L.R.C.P.Lond.

DIFFICULTY OF ACCESS TO THE OPERATION AREA.

OF this there are two varieties:—

1. That peculiar to the particular operation. This is of relatively rare occurrence, and is unavoidable.
2. That due to the incision being either misplaced or insufficient in extent, or to a combination of these two factors. This variety is preventable. The difficulty is created by the operator.

Don't hamper the operation by inadequate or misplaced incisions, which needlessly prolong the operation and increase the risk of suppuration by traumatising the tissues. As a general rule, few patients are injured by liberal, properly placed, incisions.

OBSOLETE METHODS AND POST-GRADUATE STUDY.

Don't employ methods which are obsolete, always bearing in mind that change is not of necessity identical with progress. A method becomes out of date, not from mere lapse of time—some methods are as good to-day as when first brought out years ago—but as soon as there is devised a safer and better means of obtaining the desired result.

The surgeon can avoid out-of-date procedures only by keeping in touch with modern developments; and to do this, regular visits to progressive clinics are essential; reading alone is insufficient. Osler has summarised the matter thus: "A doctor without a post-graduate course, was stale in five years, in a rut in ten years, out of which only a prolonged course would remove him, and in twenty years in a well, out of which nothing would bring him."

THE ANÆSTHETIC.

Don't allow the patient to be anæsthetised with chloroform, the most lethal of the general anæsthetics in common use. The statement, "the patient cannot take ether," when closely investigated is not infrequently found to mean either that the anæsthetist cannot give ether or that the surgeon has not learned to operate on an etherised patient. In general surgery, nitrous oxide (or ethyl chloride) and ether given properly and preceded by atropine, either with or without morphia, is almost universally applicable. In the exceptional cases, where ether alone is undesirable, arrange with the anæsthetist for the use of a mixture of ether and chloroform, the less chloroform the better, and thereby avoid the deaths caused by undiluted chloroform.

THE MATERIAL FOR BURIED LIGATURES AND SUTURES.

Do not bury unabsorbable material in tissues from which there is no natural outlet.

Intestinal sutures do not come under this heading, their natural exit being per rectum.

Remember that the epitaph of the buried unabsorbable ligature is "Resurgam," and use whenever practicable—which means in the vast majority of cases—absorbable ligatures, where necessary, hardened, to prevent their too rapid disintegration.

THE COUNTING OF FORCEPS AND SWABS.

Don't forget, in every abdominal case, to have the forceps and swabs counted, both before and after operation. For the coxsure operator who "finds counting unnecessary because he never leaves anything in the abdomen," disillusionment is only a matter of time.

The belated discovery in the abdomen of a forceps or swab is liable to result in an action for damages, at the trial of which the position of the operator, who has to admit that the counting had been omitted, is far from enviable. Routine checking might with advantage be extended to all the smaller articles, such as needles.

The peritoneum is not the only hiding place for forceps and swabs. A pressure forceps has been removed from the axilla some weeks after a breast operation.

The possibility of such an occurrence can only be prevented by counting the instruments and swabs in every operation in which the wound is capable of harbouring them.

OSTEOMYELITIS

In operating on cases of acute osteomyelitis, especially in children, don't omit the tourniquet, which must be kept in position until the bone cavity has been packed and the dressings applied. The oozing from inflamed bone, laid widely open, is very free, and if not prevented by a tourniquet deprives the septic patient of a large amount of blood at the very time when he is least able to withstand such loss. Also the tourniquet, by preventing the necessity for constant swabbing, accelerates the operation. When plugging the bone cavity, don't forget to lubricate the plugging material with either sterile oil or sterile vaseline. Even with this precaution, the first dressing is far from being painless.

OVARIAN CYSTS.

Don't tap or incise ovarian cysts. Whenever practicable remove them intact through a large incision.

It is now recognised that many of these cysts, though innocent in appearance, are malignant, and not a few cases have occurred in which, after ovariectomy by a small incision and trocar, the patients have returned with generalised cancer of the peritoneum owing to infection by cyst contents during the operation.

There is also a possibility that the cyst, especially if adherent to intestine, may contain pyogenic bacteria.

ACUTE APPENDICITIS.

Don't, after definitely diagnosing an acute appendicitis, defer operation in order to wait for an improvement which may never occur.

Adopt the motto of John B. Murphy, "Now is the accepted time," operate at once, and, at the end of the operation, don't forget to insert a drainage tube.

APPENDICITIS—CHRONIC.

Many as are the ill-effects produced by a chronically inflamed appendix, don't diagnose chronic appendicitis in every patient who has at some time had slight discomfort in the right iliac fossa.

How many operators really believe that an appendix which is neither thickened, adherent, inflamed, nor distended is the cause of abdominal symptoms?

Such an appendix may fairly be regarded as harmless, even though it fails to conform to the standard of normality, which appears to vary according to the fancy of individual operators.

Given an appendix as harmless as that described, the operator will be well advised in hunting elsewhere for the cause of the symptoms.

Among the many excuses brought forward to explain the removal of an appendix are the following:—

1. The appendix is too long.

What is the correct length of an appendix, and what is to be done if it is too short?

2. The appendix is "kinked."

If by this it is meant that the appendix does not form a straight line, what appendix can hope to escape? If, on the other hand, it is implied that a bend in the appendix is causing obstruction of the lumen, such obstruction will be evidenced by either distension or thickening above the "kink." Here, as in other parts of the intestinal tract, a "kink" which produces neither hypertrophy nor distension may be disregarded.

3. The appendix contained a small amount of soft faecal matter.

This is frequently found both *ante* and *post mortem* in appendices which have given no trouble.

4. The appendix was found to lie in the wrong position.

What is the correct position for an appendix, and is the appendix any the worse for running north-west instead of south-east?

5. There is nothing wrong with the appendix, but it is removed because it is useless and liable at any time to become inflamed.

In regard to the alleged absence of function, it is a remarkable theory that the decision as to removal of organs should depend on the operator's lack of physiological knowledge.

5. The practice of removing a healthy organ or tissue, in order to prevent possible degenerative changes in the part removed, is fundamentally unsound.

If the principle of removing healthy organs or tissues, on the off-chance that, if not removed, they may at some future date develop some disease, becomes generally accepted, there will be very little of the healthy human body which can hope to escape the attentions of the operator.

6. The appendix, to the naked eye, appears healthy, but the microscope may reveal something.

The microscope may, but that the revelation will explain the symptoms is quite another proposition.

Some years ago a French surgeon, after describing a hæmorrhagic form of chronic appendicitis, ventured to point out that this variety was only found in appendices to which clamps had been applied.

Operators who remove harmless appendices point triumphantly to the relief given to the patient as proof positive that the appendix was at fault. Such triumph is apt to be short-lived. The removal of a harmless appendix from a patient who is suffering from some disease other than appendicitis or who is merely neurasthenic, gives a temporary relief, not because a harmless organ has been taken out of the abdomen, but because the dread of appendicitis, not infrequently the result of the visit to the operator, has been removed from the patient's mind. Similar temporary relief might be obtained from an incision which stopped short of the peritoneum. Operations for neurasthenia are rarely, if ever, advisable. When, later on, the patient's symptoms recur, if no organic lesion can be discovered, the next stage is an operation for "adhesions," which, since they did not exist at the time of the first operation, can only be attributed to the operation for removal of the appendix. After several operations for "adhesions" have failed to cure, the patient may have some viscus fixed by sutures, or some larger operation, such as a colectomy may be performed.

SECONDARY OPERATIONS ON NERVES.

Don't jump at the conclusion that the presence of a scar in the neighbourhood of a nerve, even

though accompanied by paralysis or anaesthesia, is an indication for immediate operation.

Many of these patients, when treated by relaxation of the paralysed muscles, combined with massage and electricity, make good recoveries.

It is time enough to consider the question of operation when the above methods have failed.

The operator who, without employing such preliminary treatment, performs operations for "nerve suture," is likely to have many operations for "neurolysis," which, under such circumstances, is a euphemistic expression of the fact that the nerve was found to be undivided. By employing appropriate treatment *after*, instead of prior to, "neurolysis," it is easy to obtain good results, many of which are wrongly attributed to the operation—wrongly attributed because many of these cases recover without operation, if properly treated.

OBESITY: EPILEPTIFORM ATTACKS: RECURRENT JAUNDICE IN A GIRL AGED THIRTEEN YEARS.

By E. G. FEARNSIDES, M.D., F.R.C.P.,

Assistant Physician to the Hospital for Epilepsy and Paralysis, Maida Vale.

E. C.—, female, born November, 1901. There is no family history of neuropathy or obesity, and her parents, who married in 1894, are healthy and rather below the average in size and weight. The patient is the second of two children, and her brother, born in 1896, is healthy.*

Personal History.—At birth she was a fine baby, and since the age of seven has always been "too large for her age." Her only illnesses have been measles at the age of three, mumps at the age of five, and whooping cough at the age of seven. At the age of nine, after a fall down some steps, in which she hurt her head, her weight began to increase rapidly. Since April, 1913, she had been "subject to fits," and in April and November, 1913, and on January the 18th, March the 30th, and April the 20th, 1915, suffered from typical epileptiform convulsions. The attack of March the 30th occurred whilst the patient was under observation in hospital. In each attack she had been convulsed, lost consciousness, become cyanosed; on three occasions she has bitten her tongue, and on one has fallen and cut her cheek. The attacks are followed by drowsiness and intense frontal headache, and on two occasions have led to vomiting. After each attack, for a day or more she has been irritable and excitable. She has always been backward at school, and when she left school in April, 1913, had only reached Standard IV. Since the onset of the attacks her memory had become defective, and she is "no longer the bright girl she was." Catamenia began in May, 1914, and occurred regularly in June, July, August and September, 1914, and again in March and April, 1915; on the last two occasions the loss was excessive and continued for seven days. From time to time since February, 1915, she has "gone yellow," and since this date definite bilious staining of the eyes has been observed on several occasions. On March the 5th she was definitely jaundiced, and bile was present in the urine in large quantities, but at no time has she complained of abdominal pain or exhibited any abnormal abdominal signs. Her weight on February the 5th was 11 st. 13 lb., and by February the 19th had

increased to 12 st. 2 lb.; since this time she has been taking thyroid extract (2½ gr. daily), and her weight has fallen to 11 st. 3 lb.

The patient is an extremely stout, thickly-set girl. The skin is moist and everywhere stained a light brown colour. The mucous membranes appear healthy. There is a well-developed pad over the lower cervical spinous processes and small supra-clavicular pads, but on the whole the excess of fat is distributed over parts which about the time of puberty in girls usually show a superabundance of fat. Over the lower parts of the abdomen and upper parts of the thighs well-marked striae of a white or pink colour are present. The veins over the lower abdomen are prominent. The axillary and pubic hair is well developed and that of the scalp normal. The breasts are large and well developed. The thyroid is small. The bones of the head, trunk and limbs appear normal, and there is no evidence of any delayed union of the epiphyses. A skiagram of the skull taken in February, 1915, shows a clear-cut sella turcica of normal outline and dimensions. She is not anæmic, and a blood-count shows red cells 5,600,000 per cubic millimetre, hæmoglobin 106 per cent., and 17,500 white cells per cubic millimetre, with a normal differential count. The voice is natural.

The cardiac sounds are clear. The blood-pressure in the right brachial artery measures 125 mm. of mercury. No abnormal signs are present in the lungs. The liver and spleen cannot be felt, and to percussion are not enlarged. No abnormal lumps can be felt in the abdomen. The urine contains neither albumin nor sugar; the average quantity passed in twenty-four hours is 36 oz.

Mentally she is dull and slow. She sleeps heavily and is not troubled with dreams. Apart from the epileptiform attacks she suffers but little from headache. There is no pressure tenderness of the scalp. Vision is unimpaired and the optic discs appear healthy. Smell, taste and hearing are unaffected. Ocular movements are well carried out, and there is no nystagmus. The pupils react normally to light and accommodation. The functions of the other cranial nerves are performed normally. The knee-jerks and ankle-jerks are brisk, and the abdominal reflexes readily obtained. Both plantar reflexes give a flexor response. The movements of the spine are normal and the action of the sphincters controlled.

Progress.—Between May the 13th and November the 5th, 1915, she has taken daily 30 gr. each of the bromides of potassium, sodium and ammonium, and 2½ gr. of thyroid extract, and during this period her general health has been fairly good. There have been no further attacks of jaundice, but she has suffered from generalised epileptiform attacks on August the 18th, October the 8th, and on October the 9th, and, apart from the attacks, has complained on several occasions of severe generalised headache lasting for a day at a time. Her weight has gradually increased to 12 st. 11 lb. The catamenia have been irregular and on two occasions have lasted for twenty days continuously. The excess of fat and its distribution have altered little, and the description of the patient and her nervous signs written in May, 1915, is still applicable. Mr. G. W. Thompson reports that the condition of the optic fundi has not altered, and Dr. Gilbert Scott finds that between February and November, 1915, no changes in the outlines of the sella turcica, as seen in the radiogram, have appeared.

Comments.—Obesity in young girls at and about the time of puberty is a normal phenomenon, but as to the factors at work in its causation little is known. In recent times, with the gradual increase in knowledge of some of the functions of the endo-

* The case was shown at the Neurological Section of the Royal Society of Medicine, on May 13th, 1915.

crinic system of glands, much speculation, based on slender foundation in fact and few adequate observations, has been published tending to incriminate alterations in the functions of the thyroid, the pituitary, the pineal, the adrenal, and gonadic glands, and the interrelations of these, as the underlying factors in its causation. At puberty it is known that this system bursts forth into enormous activity. Is this girl an example of a rather severe obesity of the type which falls into Sir James Goodhart's class of "normal abnormalities"?

The association of obesity with epileptiform convulsions would seem to imply that both may have a single cause. Can this lie in the pituitary body or pineal gland? The distribution of the fat conforms more closely to the distribution seen in normal girls rather than that which is found in examples of dystrophia adiposo-genitalis due to sub-pituitarism, and, moreover, in this case secondary sexual characters in the hair and breast are present, and menstruation, though irregular, occurs periodically. By our usual criteria no evidence of pituitary involvement can be demonstrated, and as far as I know pineal disease has never been associated with obesity.

Hypernephroma often occurs with precocious sexual or physical development and hirsuties, and is associated with obesity; in these patients the fat is distributed in a manner which recalls the obesity of an oldish man of alcoholic habit. The recurrent attacks of jaundice suggest the possibility of abdominal disease, but here again investigations of the abdomen and of the functions of the liver and pancreas have so far proved negative. At the present time no definite diagnosis can be made. The case has been reported in order to stimulate the collection of observations which may enable us to gain further insight into the causes of obesity in young people, a subject upon which the gaps in our knowledge are still so large.

OXYGEN AND CANCER.

By LIONEL CRESSWELL,

Burley-in-Wharfedale.

PART II.

THE considerations subsequently set forth by Binz are of much importance in their bearing on the causation of cancer. He continues: "We may now pass on to consider one action of arsenic which has a special bearing on its therapeutic application. I refer to the increased *development of the animal tissues* which results from its cautious use. (11)

"In those countries where arsenic occurs native, as a mineral in the form of sulphides, and is consequently easily obtained, it seems to have been known from an early period that horses looked better and displayed greater activity if arsenic were added—in carefully adjusted quantities—to their food. The people themselves also took it, and consequently in these districts habitual arsenic eaters are to be found, who systematically use the poison for the same purpose. Certain accounts from Styria were published, and were received with some incredulity at first. . . . The government authorities then requested the Styrian doctors to furnish accurate reports on the matter, and the above mentioned statements were entirely corroborated.

"The arsenic eaters are met with chiefly in the north and north-west of Styria. . . . Arsenic eaters are sometimes though rarely found amongst women. . . . For the present it is impossible to explain how the system becomes accustomed

to strong poisons, though the fact is daily observed with regard to nicotine and morphine. A conceivable explanation may be furnished by the changes in the amount of oxygen in the cellular protoplasm which are induced by the action of arsenic; we can at least imagine that the organism gradually adapts itself to the increased activity of an element—namely oxygen—for which it has a close affinity.

"As far back as 1863, it was reported that two young rabbits, to each of which (arsenic) was daily given in its food became very lively . . . and grew to an extraordinary size.

"Numerous experiments were made by Geiss on rabbits, fowls and young pigs; he obtained most surprising results. . . . The bones of those animals to which arsenic was administered can be distinguished at a glance from those of the control animals. The offspring of a mother to whom arsenic has been given all died at birth, apparently because they were too large. . . . Consequently, in this case also, the arsenious acid acted as a stimulus to the development of tissues. The condition of the individual bones was essentially the same as that produced by Wegner from the administration of phosphorus. More recent observations furnish results closely agreeing with the above and lead to the following conclusions:

"Small doses of arsenic cause proliferation of the cells of the liver and kidneys. In animals, small doses of phosphorus act on the liver in precisely the same way as arsenic—that is to say they stimulate the growth of the various cells, larger doses give rise to fatty and vacuolar degeneration and destruction of the liver cells. Neither the blood nor the vascular system is affected. (12)

"Phosphorus and arsenic, moreover, do not induce these morbid changes by acting to any extent on the structures surrounding the cells—that is to say, by lessening any external resistance to the development of the cells themselves. *At the same time mitotic or indirect division of the nuclei is distinctly manifest.*"

Elsewhere, discussing the therapeutics of phosphorus, Binz says: "The fatty degeneration appears, therefore, to depend altogether on the direct contact of the phosphorus with the living protoplasm. Other chemical bodies which have strong oxidising or reducing action also induce fatty degeneration of the cells, and paralysis of their special functions. *Everything which contains oxygen in an active form or which can cause it to become active—and phosphorus is a body of this nature—will produce these changes very rapidly.*" The italics are mine.

Binz continues:

"I have here a large glass jar which contains a little water. In this is placed, but not entirely submerged, a stick of yellow phosphorus. The jar and its contents have been in a warm room for several hours. If now, I dip a broad piece of filtering-paper moistened with mucilage of starch containing potassium iodide, into the jar, the paper immediately turns blue, for the air in the jar contains ozone, by which the potassium iodide is decomposed in the usual manner. The formation of the ozone may be represented by the following equation:

the phosphorus anhydride P_2O_3 continuing with

the water, and remaining in solution as phosphorous acid $P_2O_3 + 3H_2O = 2H_3PO_3$.

"There is no manifest reason why phosphorus, when it has been introduced into the circulation, should not be transformed in a similar way, by the oxygen of the hæmoglobin.

"It is immaterial whether, in these changes, we regard the active atom of oxygen in ozone as a strong oxidising or as a powerful reducing agent; as is well known, ozone can, according to circumstances, act in either way. Neither does it matter if we attribute the changes to the intermediate formation and rapid oxidation of phosphoretted hydrogen, the action of which is said to be very similar to that of finely divided phosphorus. The mode of action may vary in some details, but the conclusion to which I have arrived is, that the changes in the system produced by phosphorus result from the development of active oxygen through the agency of that substance."

"We have further to notice that the oxides of phosphorus are either not poisonous, or if they are, the effects they produce differ both as to their nature and intensity from those of phosphorus itself.

"If this unusual liberation of oxygen within the cells which is antecedent to its being transformed into the active state, takes place slowly, it then acts as a formative force, and so may promote cellular growth; if, however, it occurs in too large a quantity, or continues for too long a time, it acts as a disintegrating force which endangers the structure of the cell and therewith its vital activity." Again the italics are mine.

"The explanation I have here offered is, at all events, not a strained or improbable one, it is based on facts, and also explains the individual facts, and it may be allowed to stand until a better has been offered." (13)

Much more that Binz has recorded concerning his investigations in relation to the pharmacological and toxicological properties and effects of phosphorus, arsenic, bismuth, lead, silver, mercury, permanganate of potash, chloride of lime, chlorate of potassium and animal and vegetable charcoal might be quoted by me in additional support of my oxygen hypothesis of cancer causation. For the purposes of this essay I need cite no more, but proceed to point out the bearing of what is cited on my theory.

Over and over again it has been proved that protoplasm possesses marked reducing properties, that is to say it has such a great affinity for oxygen, that possibly it can take it direct and greedily from the air as some say, but at any rate that it can often do so when there is a third substance present. In the living forms of anaerobes it can extract it from substances like sugar in which it is in chemical combination. Binz's experiments prove that it can separate it from arsenic, phosphorus, nitrogen and other metals and halogens, and that it is the oxygen—nascent active atomic—or whatever else you like to call it that is the formative, destructive, preservative, antiseptic or poisonous element according to the strength of the dose and action or way it is viewed. Oxygen, is short, may be the means of life or the means of death to any living organism with which it comes in contact. If the transformation into the active state and transference to the living cell takes place minutely and slowly, it acts as a formative force. If the transformation occurs in

too large a quantity or the transference continues for too long a time, oxygen acts as a disintegrating force endangering the structure of the cell and its vital activity. Vitally necessary as oxygen is to the living organism, the mechanism by which its absorption takes place is so rigid and inelastic that when anything gets out of gear or breaks down it is impossible to replace it by any other means. Were the mechanism less rigid and inelastic the being would be in danger of over-oxidation, that is of self-combustion. It is this rigidity and inelasticity that I conceive leads to the onset of cancer. From one or another cause, constitutional, temporal (senility) or accidental, the whole system, or the part affected by the disease falls into a condition of cellular oxygen hunger. The individual cells are, to employ a familiar illustration, in the unhappy predicament of the prisoners in the infamous Black Hole of Calcutta, which had only one small window—more numerous than the supply of oxygen is sufficient for. In the struggle for existence those nearest any supply of oxygen, like the twenty-three of the hundred and forty-six unfortunates who came out alive from that ghastly June night in 1756, survive at the expense of their fellows. In the case of arsenic cancer, as in that of sweeps' cancer, when from any cause exposure of the oxygen-hungry cell-protoplasm to arsenic or soot takes place, passage of oxygen results. This passage may at first be so violent, that simultaneous reducing and oxidising processes may occur on either side to the destruction of the cells immediately implicated. But there comes a point where some cell or other, (14) more or less removed from immediate contact with the oxygen supplying or nutrient substance, experiences only its restorative and not its destructive force. From protoplasmic restoration to protoplasmic formation and growth is a single step. And from growth to cell division and proliferation is only another.

Sir Alfred Pearce Gould (15) says, "The cancer cell is only a variation of a normal cell . . . it possesses neither in structure nor powers anything not found in the healthy cell. Let me rapidly mention the established facts about the living cancer cell. First, it possesses a great power of continuous multiplication. . . . The second characteristic is that it retains the inherited limitations to type of the cells among which it first appears. . . . Thirdly, cancer cells develop and differentiate but little and irregularly. . . . The development of the cancer cell is neither purposeful nor effective. . . . Cancer cells exhibit periodicity in their growth." And Roger Williams (16) says, "as E. B. Wilson, the chief exponent of modern cytological knowledge for English-speaking people, has so well said in the latest edition of his useful book (17): 'All the facts at our command indicate that the tissue cell possesses the same morphological organisation as the egg cell or the protozoan, and the same fundamental physiological properties as well.'" There can be no doubt, as Spencer and Darwin surmised, that the fundamental properties of somatic and germ cells are the same in kind and that they differ only in degree.

An embryo and a cancer have much in common. The difference between them is that one is a sexual and orderly manifestation of reproduction in the parent body, the other is an asexual and disorderly growth. Geiss tells us of the surprising results

he obtained by the administration of small doses of arsenic on rabbits, fowls and young pigs. The offspring of a mother to whom arsenic had been given all died at birth, apparently because they were too large. Zeigler and Oblensky's experiments furnish similar results. Small doses of arsenic caused proliferation of the cells of the liver and kidneys, not by acting to any extent on the structures surrounding the cells—that is to say by lessening any external resistance to the development of the cells, but by acting chiefly on the cells themselves. *At the same time mitotic or indirect division of the nuclei was distinctly manifest.* This latter is an especially interesting observation of Binz, inasmuch as Ross (18) recording his experiments in the excitation of leucocytes by means of certain alkaloids states, that he and his co-worker Cropper observed certain excited movements of a similar form to be caused by arsenic, but that when the effects of oxygen were tried on leucocytes by bubbling the gas through the jelly the action seemed to be negative. Herein is exhibited the difference in action between quiescent molecular oxygen and the active atomic form postulated by Binz in the case of arsenic poisoning and cell-proliferation, and by myself in the case of cancer causation. Once the morbid process of cancer growth has begun, it continues at the expense of the whole system even after the original stimulus has ceased. The re-invigorated proliferating cells flourish parasitically at the expense of neighbour cells, their imperative oxygen demand leading in some cases to very severe cachexia.

"There are indications," say Adami and McCrae, "that the actively growing carcinoma cells feed upon the pre-existing tissues, and apparently by phagocytosis, by extra-cellular ferments and by preparatory solution, the tumour cells replace the tissue cells and use them as food stuffs." "The growth of the cancerous mass and its suicidal infoldings by pressure on surrounding parts tend to constrict blood vessels, causing central degenerative changes. This can be readily understood, since the outermost cells obtain the best of the oxygen and food supply, while the inner ones are deprived of these and also of a free outlet for their own end-products. The degenerative changes are atrophic or necrotic or at times autolytic so that the centre part of the tumour may become fluid. Similarly in a surface tumour the most superficial cells are farthest from the blood supply and are, therefore, liable to necrosis." (19)

Those who are interested in the problem of the cause of cancer may consult my essay in *The Nineteenth Century* for other considerations. From among them I may recite the frequently expressed opinions of great authority; (1) that any parasitic theory of cancer fails even to be a satisfactory working hypothesis; (2) that the probability, almost the certainty, is that cancer has one scientific cause acting under a great variety of conditions, and (3) that some day a simple therapeutic agent of universal potency in the animal creation would perhaps be discovered, one which would be found to have a profound influence on the causation, growth and arrest of the cancerous process. To apply the words of Binz, the oxygen hypothesis I have offered is at all events not a strained or improbable one. It is based on facts and also explains the individual facts and none other fulfilling these

conditions has been offered before. My path is not "a mere airy track, fabricated of ideal cobwebs, but a solid and broad bridge of facts." Mere speculation has no part in it. My starting point was a thorough study of all the available literature on malignant disease, a careful regard to the recorded facts and ascertained factors. In the midst of all the welter of literature and statistics, records of experiments, theories of causation (over 2,000 in number) the one striking fact of "the enormous susceptibility of chimney sweeps which is too great to be explained by chance," as the author of the article "Cancer" in the tenth edition of the *Encyclopædia Britannica* puts it, together with his concluding pregnant suggestion that "no doubt the case of the chimney sweep contains one of the keys to the problem of cancer causation" arrested and focussed my attention. From general knowledge of the nature and properties of amorphous carbon of which soot is a form, the question was aroused in my mind whether the influence of oxygen as a factor in the causation of the disease had been fully considered from all points of view. As I moved forward in systematic study of the literature of cancer, the more I became impressed with the absence of such consideration. It is difficult to believe that a false hypothesis would explain so many classes of facts as mine does. As Darwin said in a letter to Dr. Asa Gray, "an hypothesis is developed into a theory solely by explaining an ample lot of facts."

CLINICAL RECORDS.

A NOTE ON COMMOTIO CEREBRI, OR SHELL SHOCK.

By J. C. McWALTER, M.D., F.R.F.P. AND S.,
Of the R.A.M.C.

OPINIONS on "shell shock" oscillate between extreme limits. In the earlier days of the war a medical officer who dealt with the question in his thesis for the M.D. degree of Trinity College, came to the conclusion that there simply was not any. On the other hand, Dr. Mott and his colleagues at the Royal Society of Medicine have been horrifying us with the list of complaints, from gibbering idiocy through deaf mutism, blindness, deafness, spinal and nervous disintegration, spine shock, nerve shock with neurasthenia, to mental breakdown, which mark the subsequent path of

the soldier who has been subjected to injury as a consequence of shell warfare.

Nobody doubts that Dr. Mott is nearer the truth. All of us who have come into professional contact with sick or wounded soldiers from the front have been struck by the overpowering importance of the nervous or physical elements of their disorder—of a profound *commotio cerebri* or *commotio nervorum*, which so altered the nervous outfit and outlook of the soldier as to make him a new, and generally a much less useful and less admirable man.

The species of "shell shock" to which I wish to draw attention is a much less dramatic type of case than that spoken of by Dr. Mott and his colleagues. It is a species of nervous instability, apparently a molecular instability of the cerebral cells, which may not be marked by any definite physical signs until the soldier is subjected to some slight extra strain, as of heat, or hunger, or travel, and which then manifests itself by a sudden breakdown, a complete collapse, bearing all the classical signs of compression of the brain with insensibility.

This is the kind of case I refer to: The city ambulance brought to the hospital a soldier who had been picked up quite insensible in the public street. He was absolutely unconscious, with slow, stertorous breathing, dilated pupils, flaccid in his limbs, unresponsive to any ordinary stimulus. There was no sign of any injury to account for his condition, and no evidence of alcoholism.

He was left in bed for some hours, the usual means to bring back consciousness being applied in vain. The pulse got slower, the respiration more sighing, the force of the heart-beat more diffused and laboured. He presented the very picture of dissolution.

Towards evening, about eight hours after he was brought in, he moved his eyelids and his lips. Being asked his name, he muttered some response. About ten hours after the stertorous respiration became modified, and the couple of drops of croton oil which he had been given operated. Finally a natural sleep supervened, out of which he could be awakened 18 hours after the onset of unconsciousness. In a few days after he was fairly well, but dazed and confused.

He had never received any definite injury except the constant shocks from the bursting of shells and the scattering of shrapnel. Such a man, however, must always be liable to the like attack of *commotio cerebri* on being faced with any great strain or excitement. It is scarcely fair or wise to send them back to the trenches, and yet, in the absence of definite physical stigmata of disease one can scarcely certify them as unfit.

Age and temperament are perhaps the determining factors. This man was bright, cheery, rather young, and anxious to get back. Those verging on forty get depressed, lachrymose, gloomy, and generally unfit for further strain.

If, the war being over, such a man, in the course of his civil occupation, developed the like symptoms with a fatal result, would his death be the direct consequence of the War Expedition? I submit that it would. There is a great responsibility on medical officers who are asked to state whether a patient's condition is due to the effects of the campaign, to take every care of the patient's interests as well as those of the Government, for one may easily do a man who has sacrificed much for his country irreparable harm if one lightly asserts that his broken health is not due to his Army services.

THE Portuguese Red Cross Society at Lourenço Marques is organising ambulances for service in Nyasaland.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE ULTRA-VIOLET RAYS OF THE SIMPSON LAMP.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of April 5th a paragraph suggests a commission of inquiry as to the origin and effects of the so-called Simpson or "S-rays." In January last, at the Electro-therapeutic Section of the Royal Society of Medicine, evidence was given by physicians of repute who had carefully investigated the physical and therapeutic properties of the Simpson apparatus. It was conclusively shown that it gave out ultra-violet rays in greater abundance than the Finsen lamp, and in about the same quantity as tungsten electrodes. Hence there is in this much-advertised lamp no new discovery of new rays, as was the case with the X-ray, but only a new source of already well-known rays. For this reason it is inaccurate to speak of "Simpson rays," or "S-rays"; the only accurate descriptive title is the Simpson lamp for producing ultra-violet rays. Evidence as to the value of this lamp was also brought forward, and it was clearly shown that no one who was unfamiliar with the effects of other methods for producing heat and light could possibly judge as to the comparative effects of the new lamp. Dr. Sequeira proved that its rays could not penetrate a thin cotton thread, much less the human skin. The superficial effects of the lamp have yet to be proved superior to those obtained from other sources of ultra-violet radiation. In the interests of the public and the profession misled by advertisements, it is time these facts were widely known.

I am, Sir, yours truly,

AGNES SAVILL, M.D.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PSYCHIATRY.

MEETING OF THE SECTION HELD ON MARCH 28TH, 1916.

The President, DR. F. W. MOTT, F.R.S. in the Chair.

DR. BERNARD HART read a paper entitled
THE PSYCHOLOGY OF RUMOUR.

Rumour he defined provisionally as the transmission of a report through a succession of individuals, the product of the narratives of a series of witnesses. The reliability of a rumour depended on the accuracy with which such statements were transmitted, and, ultimately, upon the accuracy of the report furnished by the first member of the series, who was assumed to have seen or heard the occurrence itself. The report furnished by the actual witness of an event constituted "evidence" in the legal sense of the term, and it was clear that an investigation of its psychology must logically precede that of rumour. In former days the criterion of reliability was held to be the moral character of the witness. The question debated at that period was whether a witness was honest or dishonest, or whether he was trying to mislead, with definite conscious ends in view. If such scrutiny resulted in the individual's favour, all his evidence was accepted. Nowadays, however, the

reliability of each individual statement was separately estimated, each possible influencing factor being taken cognisance of, including the unconscious action of political and other bias. Extensive experimental investigations into the psychology of evidence had been carried out, especially by Stern and his school. The method adopted generally consisted of submitting a predetermined experience to a number of subjects, who were subsequently required to furnish a report of their experience. These reports were compared with the original experience, and the various results in that way evaluated.

Two methods of obtaining the report were employed: the narrative and the interrogatory (cross-examination). These experimental investigations completely upset the naïve views still generally held by the laity—namely, that evidence given with the best knowledge and interest was a correct reproduction of actuality; and, secondly, that evidence which was false must be due to either lying or culpable carelessness. Completely correct reports were not the rule, but the exception. One investigator found, in 240 reports, only 2 per cent. of errorless narratives. The average reporter, when no suggestive or leading questions were employed, exhibited a co-efficient of accuracy of only 75 per cent. Attestation was not found to be a guarantee of accuracy, for even in sworn testimony 10 per cent. of errors were found to be present. On increasing the time-interval between the event and the report, it was found that though range and accuracy were both diminished, the degree of assurance of the reporter showed a surprising constancy. Hence a person's degree of assurance and readiness to swear to the truth of his testimony depended on the character of the person rather than upon the quality of his memory. Evidence given by children should be accepted with the greatest caution, for the assurance of children was relatively high, while their capacity for reproducing what they had seen was very low.

After a historical *résumé* of the work of previous investigators, Dr. Hart proceeded to analyse the psychological factors leading to the perversion of evidence, dividing the processes involved into perception, conservation and reproduction, and especially dwelling upon the part played by "complexes" in the distortions affecting each of these processes. The facts of pathology were of great help, and a consideration of hallucinations, illusions, the paramnesias of alcoholics and paralytics, and particularly of the condition known as *pseudologia phantastica*, showed precisely the same causes at work as in the perverted evidence of the normal man, but, of course, in a more exaggerated degree. The action of phantasy was of the greatest importance, both in pathological conditions, such as hysteria, and in the production of certain rumours in normal men.

The author passed on to consider rumour as a social phenomenon, and analysed its relation to the psychology of the crowd. The views of le Bon, Conway and Trotter were described and criticised. The peculiar susceptibility of the crowd to the action of "herd instinct" explained the ease with which non-rational opinions and beliefs were embraced by it, and hence its increased liability to the acceptance and propagation of rumours. During a great war, herd instinct was stimulated to a maximum degree, and the prevalence and vitality of rumour were, for the same reason as in the case of the crowd, also greatly enhanced.

Dr. Hart concluded by enumerating and classifying the various types of rumours, analysing the factors responsible for their origin, and illustrating his contentions by examples drawn from recent history.

The ensuing discussion was participated in by the PRESIDENT, SIR GEORGE SAVAGE, Mr. J. C. FLUGEL, Professor H. W. CARR, Dr. W. H. B. STODDART, Dr. PERCY DUNN, Dr. ERNEST JONES, and Mr. J. HERBERT PARSONS. The author briefly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, MARCH 3RD, 1916.

SIR JOHN W. MOORE in the Chair.

SOYA BEAN (*GLYCINE HISPIDA*) AND ITS USES IN PHYSIOLOGY AND MEDICINE.

DR. WALTER SMITH read a paper on above. Attention was drawn to its important dietic and economic applications, which admitted of considerable extensions, if its cultivation were extended in our colonies, especially in South Africa. The seeds are free from starch and sugar, and had been utilised in the treatment of diabetes. Takeuchi, a Japanese savant, discovered that the bean contained a specific ferment, urease, which rapidly converted urea into ammonium carbonate. The general principles of enzyme action were briefly mentioned, and the modes whereby they operate. The relations of ordinary urea to ammonium cyanate and of sulphur urea (thio-urea) were discussed, and the mutual reversibility of the process in each case was experimentally shown. The almost immediate influence of urease in converting urea into ammonium carbonate was demonstrated, and it was pointed out that urea had recently been discovered in a number of plants, up to as much as 3.5 per cent. in a fungus. A practical point in connection with urease was its application to the quantitative estimation of urea.

Dr. KIRKPATRICK asked whether the estimation of urea could be carried out in clinical work, or must the urea be in a pure state.

Dr. PARSONS referred to the almost invariable presence of starch in so-called "diabetic foods"—he had once found as much as 60 per cent.—and thought soya bean might prove very useful in this respect. He was very glad to hear of this method of estimating urea, as he had found the hypobromite method unreliable. He would like to know how urease was prepared commercially, and where it could be obtained.

Mr. CRAIG said that soya bean had been in use as a cattle food for some time. In some cases cattle had died in a rather mysterious way, and he would like to know whether urease could act on any other nitrogenous substance.

Dr. W. G. SMITH, in reply, said that the estimation of urea by urease was quite applicable to clinical work, and was, in fact, a very simple and easy method. In the case of cattle urine an estimation was afforded of the allantoin nitrogen also.

MISS ELIZABETH WEIR, of Edinburgh, left personal estate in the United Kingdom valued at £68,260, of which £48,496 is Scottish estate. The testatrix left, among other bequests: £5,000 to the Royal Infirmary, Edinburgh; £1,000 each to the Royal Edinburgh Hospital for Incurables, the Royal Victoria Hospital for Consumption, and £500 to the Royal Edinburgh Hospital for Consumption.

MR. THOMAS JAMES CARLESS, Richmond, left £100 each to the Royal Hospital, Richmond, and King's College Hospital, and £300 to the Medical Mission Auxiliary Church Missionary Society for endowing a bed at Kirman, Persia, to be called the "Henry Carless Bed."

OBITUARY.

**SIR THOMAS B. CROSBY, M.D., F.R.C.S.,
LL.D., LONDON.**

ALDERMAN SIR THOMAS BOOR CROSBY, M.D., who was the first doctor to serve the office of Lord Mayor of London, died on April 6th at his residence in Gordon Square.

He was born in 1830, at Gosberton, in Lincolnshire, where his father was a farmer. He was educated at a local grammar school and at University College, London. After his medical training at St. Thomas's Hospital, he qualified M.R.C.S., L.S.A. in 1852. In 1860 he became F.R.C.S. and two years later took the M.D. St. Andrews. For over 30 years Sir Thomas carried on an uneventful professional career in the City, in the course of which, in 1871, he filled the presidency of the Hunterian Society.

It was not until 1877 that he took any part or interest in municipal affairs, and this came about by chance. Happening to be present at a by-election for the Court of Common Council in the Ward of Langbourn, where he was an elector, he was persuaded to become a candidate, which he only consented to do on the understanding that if his seat were wanted later on by a better man he would retire. He was annually re-elected year after year until 1898, when he was unanimously elected to the Court of Aldermen.

In 1911, being then 81 years of age, he was elected Lord Mayor of London. He had at first offered, in consideration of his great age, to give way to any of his younger colleagues who might be anxious to become Chief Magistrate, but none took advantage of the proposal, and there was on the part of the medical profession a great desire that one of their number should, for the first time, fill the Mayoralty of the City. On leaving the Mansion House, Sir Thomas resumed his professional duties, and attended to his practice till stricken down by his fatal illness a few days ago.

**SIR ALEXANDER R. SIMPSON, M.D., D.Sc.,
F.R.C.P., LL.D., EDINBURGH.**

WE regret to record the death of Sir Alexander R. Simpson, formerly Dean of the Faculty of Medicine, Edinburgh University. On April 6th he was knocked down by a motor-car near his residence in Queen Street, Edinburgh, and died shortly afterwards from his injuries.

Alexander Russell Simpson was born in Bathgate, West Lothian, in 1835. He was the second son of Mr. Alexander Simpson, and married a daughter of Mr. Freeland Barbour, of Bonskeid and Gryffe Castle. He received his early education at Edinburgh University, where he was apprenticed to that distinguished man of science, Professor John Goodsir. As a student he was elected one of the presidents of the Royal Medical Society.

For seven years afterwards he assisted his uncle, Sir James Young Simpson, the discoverer of chloroform. In 1870 he was appointed to the Chair of Midwifery and Diseases of Women and Children at Edinburgh University, which he held until 1905. He filled the office with much distinction, and the religious work among students which he carried on enthusiastically won him a large measure of regard. He wrote a number of memoirs and edited his uncle's lectures on the diseases of women. He was knighted in 1906. In that year his old University conferred on him the degree of LL.D. In 1902 he received the honorary degree of Doctor of Science from the Victoria University.

**DR. WILLIAM BROWN RICHARDSON, M.R.C.S.,
BLACKPOOL.**

THE death occurred suddenly on March 30th of Dr. William B. Richardson in his sixty-ninth year. Educated at Leeds, deceased qualified M.R.C.S. in 1875. He was a well-known figure in Blackpool where he had been in practice for 40 years. He was one of the founders and a generous supporter of the Blackpool Victoria Hospital, being honorary surgeon to the institution for 20 years.

**DR. FREDERICK M. JOHNSON, M.D. EDIN. AND
MELBOURNE.**

THE friends of Dr. Frederick Miller Johnson, of Albert Park, Melbourne, will have received with deep regret the news of his death, which occurred in Gallipoli on November 29th last. He was a nephew of the late Sir William Gull, received his medical education in Melbourne and Edinburgh and graduated at both Universities. He pursued his post-graduate studies in Vienna and Heidelberg. In 1889-90 he held the post of Resident Medical Officer at the Royal Waterloo Hospital for Children and Women, London, and became a great favourite with all the members of the staff; not only because of his pleasant manners and invariable good humour, but also on account of the conscientious and satisfactory manner in which he carried out his duties. Later he practised in Albert Park, Melbourne, with much success, and was very popular with his colleagues in that city.

It is only two years ago that in the spring of 1914 many of Dr. Johnson's old friends had the pleasure of welcoming him in London, where he was taking a holiday in the company of his daughter. At the outbreak of the Great War Dr. Johnson, with patriotic ardour, joined the 6th Field Ambulance of the Australian Imperial Forces. In the summer of 1915 he spent six weeks in Egypt, and was then sent to Gallipoli where he was made a Divisional Sanitary Officer and incurred many serious risks. Shortly before his death he was promoted to the rank of Major.

On November 20th, whilst carrying out his work of inspection in the trenches, there was an unusually severe bombardment by the Turks, and he was buried in a trench by the explosion of a shell; when dug out he was found to be dead. Those in higher commands in Gallipoli speak in the highest terms of the thoroughness and fearlessness with which he had performed his duties throughout the campaign.

The following passage from a letter written by Mrs. Miller Johnson may be quoted as an indication of the courage with which the wives of our fallen friends support their losses:—"I feel I have no right to complain; he died for his King and country, and some day I shall feel proud of it; just now I can only feel the terrible loss to the children and myself."

**DR. ERNEST BRICE, L.R.C.P. AND S.ED.,
L.F.P.S. GLASG., MAJOR R.A.M.C. (T.F.),
SWANSEA.**

THE death has occurred at Swansea of Major Brice, a well-known local doctor. Born in Leicester, Dr. Brice received his medical training at Birmingham, and qualified in 1896. He settled in Swansea 15 years ago. About nine years ago he joined the 3rd Welsh Field Ambulance, and upon the outbreak of war was promoted to the rank of Major. Dr. Brice held several important local appointments.

**DR. FRANCIS H. DRAKE, M.R.C.S., L.R.C.P.,
LEEDS.**

THE death has occurred, at Headingley, Leeds, of Dr. Francis Henry Drake, stated to be the last male adult descendant of Sir Francis Drake, the naval hero of Spanish Armada fame. Educated at Leeds, he took his qualifications in 1870 and 1871. After acting as House Surgeon at Hartlepool Hospital and the Leeds General Infirmary, he settled in Leeds, and was for many years doctor at Adell Reformatory School. He leaves a widow and a son.

**MAJOR C. J. HOLMES, M.D., F.R.C.S.I.,
LANCASTER.**

THE death is announced of Major Charles James Holmes at Lancaster. He was the youngest son of Mr. John Holmes, Athlunkard, County Clare, and was born in the year 1857. He received his medical education at Queen's College, Cork, became M.D. in 1882, and F.R.C.S.(I.) in 1890. He joined the Army Medical Service in 1882, and served in the Egyptian Campaign in that year, for which he was given the

medal. Major Holmes was with the Sudan Expedition in 1885 and with the Expedition to Dongola in 1896, and received the medals for both. In recognition of his services in the South African War he was awarded the Queen's medal with clasp and the King's medal with two clasps.

DR. WILLIAM G. MACPHERSON, M.B., C.M.,
BOTHWELL.

DR. WILLIAM GRANT MACPHERSON died suddenly at Bothwell on March 31st. Educated at Edinburgh University, he qualified in 1888, and went to Bothwell as assistant to the late Dr. Bruce Goff, later becoming his partner. Dr. Macpherson was Chairman of the Local Medical and Panel Committee for the County of Lanark.

REVIEWS OF BOOKS.

URGENT SURGERY. (a)

THE second volume of this magisterial work, with its 20 full page plates and 1086 illustrations, deals with the genito-urinary organs, the rectum and anus, strangulated hernias and lesions of the extremities. Reiterating the remark which we made in reference to the previous volume, the author has admirably achieved his object of teaching surgery pictorially. We recognise, of course, that surgery, as a practical art, must be *learned*, and can only be partially and imperfectly *taught*, but in the hands of a man who has acquired by practice the indispensable minimum of manual dexterity, such a volume is of inestimable value.

Urgent surgery comprises minor as well as major interventions, and both categories are dealt with, so that while many operations are of so elaborate a nature as to interest only the pure surgeon, there are plenty of others that will appeal to country and colonial practitioners—in fact, to all those who, by temperament or under the strain of conditions of environment, are prepared to face whatever emergency may turn up. We know no other work that can compete with this volume in this respect. No detail is too inconsiderable for notice, no intervention too complicated for description.

Urgent surgery will be found to comprise such interventions as colpotomy, the relief of hæmatocolpos, curettage of the uterus, and even perineorrhaphy. It ranges from incision of a vulvo-vaginal abscess to decapsulation of the kidney for anuria, from paraphimosis to the treatment of complicated strangulated herniæ, touching *en route* on such topics as the removal of foreign bodies from the urethra and rectum, in reference to which the author has many ingenious tips to give.

The most important section of the volume is devoted to injuries of the extremities: dislocations, fractures, crushes, damage to nerves and vessels, etc., and the treatment of diseases such as osteomyelitis. Much of this comprehensive section has a very urgent direct bearing on war surgery and, incidentally, very useful information is given on the *technique* of plaster fixation apparatus, the which are far more generally employed in France than in England.

We can confidently predict popularity for this work, appealing as it does to the surgeon, the specialist and the practitioner, all the more so by reason of the sprightly fluency of the text, which has not suffered unduly from translation from French into English.

This review would be incomplete were we to omit a few words in praise of the illustrations drawn by Dr. E. Daleine and A. Lenbo (729), of which we cannot speak too highly. They are remarkably life-like, and skilfully delineated, and admirably reproduced on opaque art paper. Close upon 200 of the illustrations are from original photographs and there

(a) "Urgent Surgery." By Felix Lejars, Professeur Agrégé of the Faculty of Medicine of Paris, Surgeon to the Hôpital Saint-Antoine, etc. Translated from the 7th French Edition by Wm. S. Dickie, F.R.C.S., and Ernest Ward, M.D., F.R.C.S. (Third English Impression.) Vol. II. Bristol: John Wright and Sons, Ltd. 1915. Price 25s. net.

is a striking absence of the stereotyped diagrammatic drawings to which we have become accustomed—in short, the work is original, artistic and complete.

PHYSIOLOGY FOR NURSES (a).

THIS is a clearly written and fairly concise introduction to the science, though perhaps tending to overlap the boundaries of an elementary book. If those who have their training really judge it necessary that nurses should be taught in their physiology lectures such details as the mechanism of the larynx and the Hughlings-Jackson view of brain-levels, then their third-year lectures should be time enough for subjects which are often a stumbling-block to junior medical students. Indeed, we imagine that the best way to use the manual would be to spread its 18 chapters through the three years of a nurse's course, with revision classes in the second and third years. We can scarcely believe that the sternest of teachers would attempt to compress all the matter of this book into the first year.

The introductory chapter very rightly reminds the student of the debt we owe to the vivisector, and we wish page 3 were further strengthened by a footnote specifying categorically some of the triumphs of experimental physiology.

From Chapter 2, the reader is taken stage by stage through the divisions of the subject, beginning with a clear and easily grasped exposition of the cell theory. "Food and Food-stuffs" is rightly treated in considerable detail in Chapter 4, though we think sufficient prominence is not given in page 28 to the importance of the harder foods to promote mastication in children. The sections on "Bone" in Chapter 9 are good, but should not the current description of the function of the periosteum as "continually forming layers of bone which bring about a steady increase in thickness" (page 82), be qualified by some reference to Macewen's criticism of this long-accepted view? This investigator has brought forward evidence which merits consideration that the function of the periosteum is not to produce bone but to limit the production of bone, osseous regeneration taking place from the osteoblasts of the bone itself. In the account of the blood in Chapter 12, the contents of the plasma should, we think, have included some mention of "complement," although we concede that the very mention of this creates difficulties in an elementary manual. Perhaps a footnote, with some reference to the modern view of Vaccines, might be added. We are rather surprised in Chapter 17 to read (page 172) that "the usual test for colour blindness is to give a person a piece of red wool and ask him to pick out from a large number of skeins of wool." &c Surely the "test" mentioned is now sufficiently discredited by Edridge-Green's work and by practical experience. Examiners for the railways, *e.g.*, seldom resort to it. In the Appendix, chiefly concerned with the examination of the urine, some reference should have been made under the Fehling test to its fallacies.

The book contains an index, but no table of contents. Most of the diagrams do not err in complexity, some are decidedly crude in drawing. In Figures 25 and 27 we note that the lines showing the capsule are not very clearly denoted, and in the line drawings additional clearness would have been gained by the use of thick and thin lines, particularly in Fig. 50 (movement of the ribs). But all these are but surface blemishes, and we can give no better commendation to the book than to suggest that practitioners of say 20 years' standing should occasionally read through a chapter or two—not a difficult task, thanks to the good type, short paragraphs, and abundant cross headings in thicker type. It will repay the sacrifice of their scanty leisure, especially if they search their memories, asking themselves to what extent they can criticise or amplify this necessarily condensed presentation of the rudiments of science.

An excellent feature of the book is that the bearings of physiology on the child, not merely on the adult, are insisted on throughout. This, as the Editor of a certain weekly would say, is as it should be.

TROPICAL HYGIENE (a).

THE "residents in tropical and sub-tropical countries" for whom this has been written, will find it impossible to invest three rupees more profitably than in the purchase of this little book. Provided that they absorb its contents, and if they do not the fault will not be the authors', it may almost be said to embody a cheap life assurance in its pages. If any fault may be found with its scope, it is that it caters more for Indian residents than for others, the writers being distinguished Anglo-Indians; but no tropical resident can fail to benefit by its pages. To the junior medical officer and practitioner it must be of great service as a compendium, while its great merit is that the non-technical reader will find little or no difficulty in its perusal. Its 52 illustrations, line and photographic, aim at clearness rather than artistic effect, and we only regret that some of the most important of the line diagrams are so reduced in size as to need a reading lens to grasp properly, thus impairing their usefulness. As a frontispiece an ingenious diagram of the two ways in which the malaria parasite multiplies is reproduced, and this would have been better if bound opposite the diagram of the life-cycle of the parasite on page 208, a diagram whose value is in inverse proportion to its size. A pleasant literary flavour is given by each of the 14 chapters being headed with a quotation, the sources ranging from "sage Hippocrates" to Meredith Townshend.

The chapter on Food in the Tropics (pp. 88 seq.) is full of valuable details, various dietaries being drawn up with their weights. The writers have a good word to say for "the now well-recognised cult of Fletcherism," and rightly denounce the practice of feeding children too exclusively on slops; they should always be allowed something requiring mastication" (page 117). It is singular how many larger works on pediatrics fail to emphasise this. On alcohol their experience is that it should be used most sparingly in the tropics, "in all its forms"; on the practice of "pegging" at the club bar before dinner they are merciless, while conceding a weak peg or glass of wine with the evening meal to the "harassed Indian official" as a digestive and nerve sedative. Afternoon tea, they counsel, is "an unnecessary and useless meal"; here we fear the loyalty of the average reader will be severely strained. With their recommendation of wool wear next to the skin we cannot agree. Surely the first use of underclothing is to absorb perspiration, and absorbability is the last use that can be claimed for wool. Cellular linen or cotton such as "Empire Mesh" or "Aertex" are altogether preferable for the purpose. In the matter of clothing, and also of food, children are not forgotten. Disinfection and the disposal of refuse receive full treatment, and the chapter on Insects and Disease is illustrated by many good line drawings, the mosquito coming in for an especially full share. Chapter 12, on the Climate of the Tropics, strikes a note of cautious hope, referring to Cuba and Panama as instances of what progress in sanitary science may yet achieve. Chapter 13, on Hygiene of Camps, now includes Malta Fever; for the fly nuisance in camp the authors pin their faith to the method of 2 per cent. solution of formaldehyde, though other means receive mention. A full chapter on hydrophobia concludes the book.

Appendix II, on the distinctive characters of certain flies, would gain by diagrams being incorporated, even though the already too large page (folding) were increased. The diagram and the description in juxtaposition would give a far clearer mental picture, especially to the lay reader.

It may be hoped that in future editions of "Lukis and Blackham" it will be found possible to include some hygienic notes for European ladies, especially on matters of gestation and nursing. Some references should also have been made to Prickly Heat, frequently one of the worst troubles, it can hardly be called a minor one, of Anglo-Indian life.

TUBERCULOSIS IN CHILDREN. (a)

DR. BARTY KING has rendered signal service to English-speaking members of the medical profession in making known to them the work of Dr. Anthon Ghon, of Prague, in connection with the primary lung focus of tuberculosis in children. It may be urged that, after all, the discovery of such a lesion is chiefly of academic importance, since the tracheo-bronchial lymphatic glands invariably became infected with tubercle early in the course of pulmonary tuberculosis in childhood. The initial focus, indeed, is in danger of being overlooked altogether, even at an autopsy, for the secondary manifestations are apt to mask the primary. As far back as 1876, Parrot had formulated this view of similar adenopathies," according to which the tracheo-bronchial lymphatic glands may be regarded as the "mirror of the lungs." Later on, Kuss and Albrecht investigated the subject further, and these observers were convinced of the importance of carefully searching for the tubercle in the lung corresponding to the affected bronchial lymphatic gland. Dr. Ghon has sought to confirm these views and in the present work these results are given of his autopsies upon 170 cases of tuberculosis in childhood in which primary lung foci were found. In the majority of cases only a single pulmonary focus of disease was found, and of these the larger number showed dry caseation. In 114 of the cases, changes in the pleura were also discovered. The right lung showed more primary foci than the left, and the anterior surface of the upper lobe appeared to be a favourite situation. All the pathological evidence tended to show that the primary lung focus was never formed after the perforation of the altered broncho-pulmonary or tracheo-bronchial lymphatic glands, but was always present before. The author regards his researches as tending strongly to support the *aerogenous origin* of the pulmonary focus in the tuberculosis of children, a theory to which no objection can be advanced on physiological or clinical grounds. Very small foci in the lungs are difficult to demonstrate, and in the fourteen cases that did not present this feature in a certain proportion of these the channel of infection was incontestably outside the lung. The practical importance of the discovery of a primary lung focus in the tuberculosis of children is obvious from the hygienic standpoint.

ON SQUINT. (b)

It is a pleasant task to read the fourth edition of Mr. Worth's classic work "Squint," if only to follow the evolution of the author's treatment of that minority of squint cases which are not cured, either by glasses alone, or by glasses and fusion training. Up to ten years ago the author had performed simple tenotomy for small degrees of squint, and the combined operation of tenotomy and advancement for larger degrees. Further experience has led him to abandon tenotomies because of the uncertainty of the result, and to treat all forms of squint by advancement alone, in large degrees of deviation the correction being divided equally between the two eyes. In this respect he has followed the path traced by Landolt. Mr. Worth has also given up the black silk suture, treacherous in its strength, for white silk; the finest plaited in all probability, though this is not stated. To render the removal of the white suture easy, he ingeniously threads a small ring of black silk on the suture at its point of crossing on the conjunctiva. This ring is picked up with forceps to lift the suture off the globe so that it can be cut across without difficulty when it is to be removed.

By employing this method of treatment, Mr. Worth has been able to cure that class of occasional squint which he calls "neuro-pathic divergence." Stress is laid on the difficulties of the operation, but if any-

Lond. and Edin., Assistant Physician, Royal Hospital for Diseases of the Chest, London, etc. Pp. xx., 172. with 72 illustrations. London: J. and A. Churchill. Price 10s. 6d. net. 1916.

(b) "Squint, its Causes, Pathology and Treatment." By Claud Worth, F.R.C.S., Surgeon, Royal London Ophthalmic Hospital. Fourth edition, pp. 260. London: Bale, Sons and Co. Price 6s.

one follows Mr. Worth's explicit directions and makes use of Pooley's method of infiltrating novocain so as to obtain complete anæsthesia the result should be perfect. By a slip at page 220 the tying of the marking suture is referred to in the plural, as if more than one of these had been used.

The theory advanced by Mr. Worth as to the ætiology and treatment of squint is now so generally accepted that one might hope in the next edition to see the scaffolding removed from the structure. If this were done and the essential parts of the theory and practice printed in a small and cheap little pocket book it should become the guide for every County Council school doctor throughout the Empire, and thereby lead to the rescue of the sight of countless squinting eyes from amblyopia, which, when untreated, is their fate. If this were done, it would be well to alter a few details—*i.e.*, to speak only of the apex of a prism, and not in one place of the apex and in another of the base.

At the same time, one might endorse Mr. Worth's statement that too little attention is paid in this country to the examination and the treatment of heterophoria, which is so lucidly considered in the pages of this admirable work.

MILITARY ORTHOPÆDICS. (a)

This is a thoroughly practical little book, and gives the author's experience and treatment in the various orthopædic conditions that may come under the notice of the military surgeon. For its size, it contains a vast amount of information and many helpful hints. The opening chapter describes the different causes and the treatment of dropped foot, whilst the final chapter deals with artificial limbs. Between these, every possible condition from spondylo-lithesis to the cure of corns is ably handled. At the end of the book there is an appendix which in its first part gives a useful table of the approximate cost of the appliances described, while the second part is devoted to the treatment of more or less permanently disabled soldiers. The author points out how the present machinery does not appear adequate, and he appends a memorandum dealing with this important subject. We strongly recommend this book.

POST-MORTEM METHODS. (b)

This book by Prof. Beattie is included in the Cambridge Public Health Series of volumes, edited by Professors Graham-Smith and Purvis. Although it gives very fully the best methods for making *post mortem* examinations, it is not merely a handbook on these methods, but the more important lesions which are found in the organs are indicated, the methods for recognition and demonstration of these are given, and the points which should receive special attention and special description are noted. In the later chapters also, advice is given as to the more important changes which should be sought in investigating a case in which a particular disease is suspected. Again, the methods which are used in making an efficient bacteriological examination, are given fairly completely, although for the actual bacteriological work following the first inoculation the student is referred to a treatise on that subject.

Some few of the directions are, however, a little difficult to follow, and would be simpler if diagrams were more used. For instance, it is recommended to make sections of the brain "parallel to its long axis." This has no meaning, as the number of possible planes of section is infinite; it is only later in the paragraph that we find that these sections are intended to be horizontal. Apart from a few such blemishes, this volume can be thoroughly recommended as a help in making a complete and systematic examination, whether the worker be a trained pathologist or a

- PUTNAM'S SONS, G. P. (New York).
Mosquito Control in Panama. By J. A. Le Prince, C.E., A.M., and A. J. Orenstein, M.D., with an Introduction by L. O. Howard, LL.D. Illustrated. Pp. 335. Price 10s. 6d.
- WERNER LAURIE, T. (London).
"An Irishwoman in China." By Mrs. De Burgh Daly. Illustrated. Pp. xi. and 295. Price 10s. 6d. net.
- WRIGHT AND SONS, JOHN (Bristol).
On Modern Methods of Treating Fractures. By Ernest W. Hey Groves, M.S., M.D., B.Sc., F.R.C.S. Pp. 286. Price 7s. 6d.
Text Book of Nervous Diseases. By Charles L. Dana, A.M., M.D., LL.D. 8th Edit. Illustrated. Pp. 632. Price 21s.

MEDICAL NEWS IN BRIEF.

Royal Victoria Hospital, Belfast.

THE annual meeting of the Royal Victoria Hospital was held on the 31st March.

The annual report stated that 3,189 new cases were received, and they, with the 258 remaining from the previous year, make a total of 3,447 intern patients treated during 1915. The daily average number of patients under treatment in 1915 was a good deal higher than in 1914—namely, 266.8 against 238.1. Amongst these was a large number of sailors and soldiers from active service, who all did remarkably well, the only death amongst them being one from pneumonia. A great number of civilians, too, who were prevented from enlistment on account of hernia or varicose veins, etc., were admitted for operation, and many a man is to-day serving his country whose services but for his treatment here would have been lost.

In the extern department 29,145 new cases were received. The daily average treated in the extern department was over 240. There were 1,598 operations performed in the wards, and 640 in the extern department, and the ambulances brought 1,500 cases to the hospital, mainly due to accidents. In the hæmatological and vaccine therapy department 303 new cases were received, and 3,500 treatments given. Dr. Houston, who was in charge, having been absent on war service for the last six months, Dr. Rankin had carried on the work of the department in addition to that of his own. In the electrical department 110 new cases were received, 4,123 treatments given, and the huge number of 1,222 radiograms taken.

Infant Mortality.

IN the House of Commons on April 5th, Mr. Walter Long, replying to Mr. King, said:—The latest figures for 1915 show that the death-rate under one year of age amounted to 110 per 1,000 births, as compared with 115 per 1,000 births in the previous ten years, and 105 in the year 1914 and 108 in the year 1913. In spite of the general restriction of local expenditure, active steps are being taken by practically all the larger local sanitary authorities to lessen infant mortality and to promote the welfare of infants generally. A large number of local authorities have appointed health visitors, who advise mothers as to the care of their infants; in most of the large towns maternity and child welfare centres have been established, at which expectant and nursing mothers receive medical advice and minor treatment; and in many places arrangements have been made for the provision of midwives and of doctors for the confinement of necessitous women and for other assistance for expectant and nursing mothers and children. My Department have distributed a grant of about £41,000 in aid of maternity and child welfare work during the financial year which has just ended.

Air Raid Effects on Child Life.

INTERESTING evidence as to the effect of air raid alarms on child life was given at an inquest held at a north-east coast town on April 5th. A local doctor attributed the death of a two months' old child to shock owing to air raid alarms. These alarms, he said, affected mothers, and that day he had seen 78 children at the local dispensary, many of whom had suffered from convulsions due entirely to air raids. They were not so young as the child in question.

The Coroner seemed incredulous, but said he had every respect for the doctor's opinions. He could understand the effect of alarms on unborn children, but could not wholly accept the view that a two months old child was susceptible to the effect of these alarms.

The jury accepted the view of the doctor and returned a verdict accordingly.

Russian Medica Mission.

A RUSSIAN medical mission, consisting of Professor Dr. Tarassevitch, Prince Alexander Galytzine, and Professors Mikhailoff and Crzenoxi, is now in England,

investigating the military hospital *régime*, and especially private initiative in the care of the wounded. The mission, which will also pursue similar inquiries in France, has been despatched by the Union of Zemstvos, or local Councils.

Fewer Birmingham Babies.

DR. ROBERTSON, Medical Officer of Health for Birmingham, stated on April 3rd that as a result of the war there were between 4,000 and 5,000 fewer babies in that city than last year. If the Empire was to be kept together the infant life must be preserved.

Birmingham Maternity Hospital.

AT the annual meeting of the Governors of the Birmingham Maternity Hospital, held on April 3rd, the House Committee reported that during 1915 there had been 544 admissions, as compared with 640 in 1914 and 532 in 1913. Fifty-seven pupil midwives had been trained; also two monthly nurses and one babies' nurse. Forty-five entered for the C.M.B. examination; forty-two passed, three failed. Twenty men medical students and two women medical students applied for training, and were accepted. Two hundred and forty-nine infants were visited in their homes by members of the Infant Health Committee; 1,908 visits were paid, and 112 infants were still being visited once a fortnight.

Royal Medical Benevolent Fund Guild.

WE have received a copy of the 6th annual report of the above. The council state that "new members have been enrolled and financial success has crowned our efforts."

The Royal Medical Benevolent Fund has now been registered under the Companies Acts of 1908 and 1913 as an association *not* for profit. It thus becomes a body corporate, with perpetual succession, just as if it were incorporated by Royal Charter or special Act of Parliament. The Guild, being an integral part of the fund, shares these privileges.

The report goes on to say "our acknowledgments are due to the Press, lay and medical, for their advocacy of our cause. Thanks to them we are now becoming better known, and one feels sure there are 'grateful patients' glad of an opportunity to show their gratitude to their own medical man by helping the Royal Medical Benevolent Fund and Guild."

The year's subscriptions are £694 12s. 11d. and donations £1,572 9s. 8d., being a total of £2,267 2s. 7d.

Doctors for the Forces.

THE Central Medical War Committee has resolved not to call up practitioners under the enrolment scheme unless and until 75 per cent. of those medical men in England and Wales who on January 5th were of military age (*i.e.*, under 45) and not holding a commission have enrolled, or have since that date received a commission in His Majesty's forces or a letter of provisional acceptance.

The committee has asked the council of the British Medical Association to consider the desirability of the formation of a compassionate fund for medical officers serving in the war.

PASS LISTS.

Royal Colleges of Physicians and Surgeons of London.

AT the second professional examination in Anatomy and Physiology, held on March 30th and 31st, and April 3rd and 4th, 78 candidates presented themselves, of whom 56 were approved and 22 were rejected. The following are the names of the successful candidates: Y. Abdel-Messiah, B.A., A. Abelson, B.Sc., D.ès-L., N. D. Ball, Margarita S. Barfield, J. S. Boruchowitz, J. A. A. Bouic, O. H. Brown, N. C. Cooper, A. N. M. Davidson, E. S. Davies, F. S. Drewe, A. Eidinow, F. K. Eskrit, F. A. Evans, P. Faraci, J. E. Fishburn, J. O'F. Fletcher, R. Gainsborough, E. S. Gawne, Nannie Gibson, C. Gill-Carey, P. E. Gorst, L. Handy, H. W. Hill, B.A. Cantab., T. R. E. Hillier, A. B. Isaacs, G. H. Johnson, E. F. Kerby, H. H. Khan,

L.M. and S. Bombay, F. W. Lemarchand, P. Lloyd-Williams, D. McClean, J. J. M. Macdonnell, C. Moffatt, J. S. Moore, A. R. Neckles, C. Nicory, A. G. Ord, L. D. Porteous, P. G. Quinton, W. E. Quitman, D. H. Richards, E. Sanders, M. C. Sarkies, H. M. Savery, W. M. S. Savery, E. A. Sparks, V. A. T. Spong, G. McK. Thomas, L.D.S.Eng., J. H. Tighe, B. M. Tonkin, W. S. Tunbridge, B.A.Oxon, J. E. de V. Van der Merwe, F. F. Wheeler, H. E. Williams, and R. Wolff, B.Sc.

London School of Tropical Medicine.

THE following candidates have passed the examinations during the term January—April, 1916:—*W. N. Leak, M.R.C.S., L.R.C.P., and H. Bayon, M.D. Genoa, with distinction; Miss V. G. Field, L.R.C.P. and S.Edin., E. A. Blok, L.R.C.P. and S.Edin., L.F.P. and S.Glasg., L.M.S.Ceylon, and J. A. Beels, M.D.

* Dr. Leak gained the Duncan Medal, this being awarded to the student who obtains the highest aggregate of marks.

University of Durham.

At the Convocation, holden on Saturday, March 25th, 1916, the following Degrees were conferred:—

Doctor of Medicine for Practitioners of Fifteen Years' Standing.—Hugh B. G. Newham, M.R.C.S., M.R.C.P., D.P.H., and Samuel A. Sittampalam, L.M. and S., Ceylon; L.R.C.P. and S.; L.F.P.S.G.

Degree of Bachelor of Medicine (M.B.).—Arthur F. R. Dove, Harold K. Graham-Hodgson, Ethne Haigh, George Irving, Arthur E. Raine, Alfred Smirhwaite, Robert Welch, B.Sc.

Degree of Bachelor of Surgery (B.S.).—Arthur F. R. Dove, Harold K. Graham-Hodgson, Ethne Haigh, George Irving, Arthur E. Raine, Alfred Smirhwaite, Robert Welch, B.Sc.

Bachelor of Hygiene (B.Hy.).—Bloomfield G. H. Connolly, M.B., B.S.Durh. (*in absentia*) and William Grant, M.B., Ch.B.Edin.

Diploma in Public Health (D.P.H.).—Bloomfield G. H. Connolly, M.B., B.S.Durh., and William Grant, M.B., Ch.B.Edin.

Licence in Dental Surgery (L.D.S.).—Harold A. Metcalfe, Douglas E. Sayce, Lawrence Somerville-Woodiwis.

Dublin University.

THE following candidates have passed the Trinity College School of Physic Hilary Term examinations:—

Preliminary Scientific Botany and Zoology.—George E. Sainsbury, Jacobus F. Van Staden.

Chemistry.—Falkland L. Cary, Ivan W. Beatty, Leo V. Clifford, Richard B. Shaw.

Physics.—Maurice Nurock, John Lait (passed on high marks); Janie M. Cummins, Herbert F. Mooney, William B. J. Pemberton (equal); Robert H. M. Corbet, Doris L. Graham (equal); Leonard Abrahamson; David J. Browne, Francis V. Small (equal); Percival I. Levitt; William J. A. Russell; Robert Dormer; Christopher J. L. Brock, Robert A. O'Meara (equal); Eileen Hilda Dowse; Elsie A. Burns; Mervyn E. McBrien; Edward H. Frazer, Thomas D. Gordon, Patrick J. Healy, Isaac Levy (equal); Charles J. Shortt; Olive Baile, William B. Fox, Joseph B. Maguire, James A. Smith, Essie S. Smyth (equal); Moira M. Brown, Richard V. Dowse, Nora Griffith, Samuel W. Jameson, James J. P. Kelly, William T. Micks, Eric R. Murray, Frederik W. Pienaar, Henry P. Stack, Herbert W. Strong, Cecil S. Wilson (equal).

Intermediate Medical, Part 1.—Anatomy and Physiology: Altwyn J. Vorster, Reuben Rosnekov, Cyril D. Brink, Jan J. G. de Kock, William R. Burns, Olive G. Blackham, Henry B. Van der Merwe, William B. Briggs, Lionel Wigoder.

Intermediate Medical, Part 2.—Applied Anatomy and Applied Physiology: Harry L. Parker, Victor M. Sygne, Crawford L. Wilson (passed on high marks); Lindley Albertyn; Patrick B. Molony; Robert M. D. Devereux; Mary C. Sheppard; Johannes C. Fouche; William L. Young; William P. Eford, Wilfred V. Pellissier (equal); William Sweetnam; Ernest E. Rollins; Kenneth Greer, Thomas H. R. McKiernan

(equal); Paul H. S. Smith; Thomas B. H. Tabuteau; Eric J. Lydon, William A. Shannon (equal); Percival A. Dormer; Leslie J. Nugent; William F. McConnell; Thomas S. McDonald; Jason G. Bird; Ethel M. Luce; Eric S. E. Mack; James A. W. Cullen, Thomas M. Bentley (equal); James M. Hill; Daniel McElwee; Olive G. Blackham; John B. McGranahan; Pieter J. Swanepoel.

Final Medical, Part 1.—Materia Medica, Pathology, Medical Jurisprudence and Hygiene: Patrick Rock, Robert W. Nesbitt (passed on high marks); Joseph R. Brennan; Hirsh Brill; William J. McClintock; Sydney V. Furlong; Harry Banks; Andries A. L. Albertyn; Arthur I. Steyn; Charles P. Chambers; Willem P. Lubbe; Crosbie Weir; Sidney A. Clark; Thomas E. Hill; Fleetwood W. P. Sullivan (Materia Medica and Pathology); Michiel C. Dippenaar (Pathology, completing examination); Millicent Hamilton-Johnstone (Materia Medica, Medical Jurisprudence and Hygiene completing examination); Hastings H. Molloy (Materia Medica completing examination).

Final Medical Examination, Part 2.—Surgery (B.Ch.): Joseph W. Bigger, Thomas Lane, Charles L. McDonagh, Louis Blumberg, Millicent Hamilton-Johnstone, Mortimer McG. Russell, Eileen G. Gwynn, Frederick J. Murphy.

Medicine (M.B.): Joseph W. Bigger, Robert C. B. Ramsay, George W. Doran, John T. Westby, Millicent Hamilton-Johnstone, Eileen Gertrude Gwynn, Rupert Gordon.

Midwifery (B.A.O.): Millicent Hamilton-Johnstone, Joseph G. Bird, Frank Healy, John T. Westby, Sydney V. Furlong, Henry S. Campion.

Diploma in Public Health, Part 1.—Bacteriology, Pathology, Chemistry, Physics, and Meteorology: Brian D. Crichton.

Part 2.—Sanitary Engineering, Vital Statistics, Public Health, Hygiene, and Epidemiology; John R. D. Holtby, Marjorie Chapman, Florence Colquhoun.

University of Glasgow.

DEGREES OF M.B. AND CH.B.

THE following are the results of examinations held during March:—

THE following have passed in the subjects indicated (A., anatomy; P., physiology; M., materia medica and therapeutics; Path., pathology):—C. O. Anderson, M.A. (A.), A. B. Austin (Path.), R. Bethune (M.), A. Black (M.), D. C. Bowie (P., M.), J. Bradford (Path.), A. D. Brown (A., P.), M. J. Cahalane (M.), T. W. Carstairs (P.), M. Chalmers, M.A. (A.), A. E. Cochrane (M.), H. A. Cochrane (M.), A. C. Connell (A., P.), E. M. E. Cumming (A., P.), W. Dempster, M.A. (M., Path.), J. C. Dow (A., P.), A. B. S. Drysdale (M.), K. H. Dyke (M., Path.), D. Finlayson (M.), J. P. Fleming (M.), T. Fleming (M.), T. Forrest (M.), A. D. Fraser (A.), K. J. A. Gillanders (M.), W. H. Gordon, M.A. (Path.), A. S. Goudie, M.A. (M.), P. F. A. Grant (A., P., M.), J. S. M'L. Gray (M.), J. G. Harrower (M.), A. Henderson (M.), J. Hislop (M.), T. J. Honeyman (Path.), M. Hyman (M.), E. P. Irving (Path.), J. Irving (M.), J. Joels (M.), R. E. Kerr (M.), W. H. Kerr, M.A. (M.), W. M. Kerr (M., Path.), J. P. Kilty (M.), A. B. M'A. Lang, M.A. (Path.), G. Lean, B.Sc. (Path.), J. Liddell (M.), J. Lipschitz (M.), F. R. Lubovius (Path.), W. W. Lundie (Path.), A. J. Macartney (A., P.), D. MacColl (A., P.), H. E. M'Coll (M., Path.), A. B. Macdonald (A., P.), R. T. M'Gibbon (M.), A. D. C. M'Gowan (Path.), T. M'Gowan (M.), J. A. C. MacGregor (M.), D. B. M'Intosh (Path.), J. W. Mackay, M.A. (M.), D. W. M. MacKenzie (M., Path.), R. H. M'Kinop (Path.), J. G. M'Kinna (A., M.), J. M. Mackintosh, M.A. (Path.), W. S. L. M'Leish (M.), J. Macleod (A., P.), W. M'Linden (M.), F. K. Macmillan (A., P.), D. Macqueen (M., Path.), A. W. M'Rorie (M.), J. M. Melvin (M.), G. A. Mitchell (Path.), W. Napier (M.), J. Nicholson, M.A. (A., P., M.), I. L. Oluwole (A.), J. Paterson (A., P.), J. W. Patterson (M., Path.), N. B. Peacock (M.), G. Pearson (M.), R. J. Peters (M.), J. B. Potter (M.), R. U. Qureshi (A., P.), I. M. Robertson (M.), J. J. Robertson (M.), F. W. Sandeman (M., Path.), T. R. Sinclair (Path.), C. L. Somerville (M.), T. Stark (A., P.), J. Stewart (A., P.), A. S. Strachan, M.A., B.Sc. (M.), J. T. Taylor (A.), J. J.

Treanor (M., Path.), J. C. Vaughan (M.), A. R. Waddell (A., P.), J. L. Walker (M., Path.), W. A. Walker (A., P.), H. D. Wallace (M.), H. Wands (A., P.), R. Wiggins (M.), G. M. Wishart (M.), R. Young (A., P.).

WOMEN.

Annetta G. T. Anderson (Path.), Ellen D. Anderson (A., P.), Mabel N. Blake (M., Path.), Grace Chatterton (M.), Margarita M. L. Couper (M.), Grace A. Fleming (M.), Margaret O. Gallagher (Path.), Mary B. Gillespie (Path.), Jane E. Hanson (M.), Janet W. Hepburn (M.), Mary E. Knight, M.A. (M.), Elizabeth C. Loudoun (M.), Mary J. Macdonald (M.), Isabella Q. M'Fadzean (M.), Margaret T. M'George (M.), May E. MacIver (Path.), Maud E. D. Mackinnon (A.), Margaret G. M'Vey (M.), Florence F. M. Milne (A., P.), Mercedes M. Morton (Path.), Elizabeth P. Y. Paterson (M.), Vida J. Perry (A., P.), Margaret I. Prangnell (A., P.), Margaret N. Robertson (P.), Agnes P. Routledge (M.), Marjory M. Scanlan (A., P.), Katherine Scott (A., P.), Margaret M. C. Steedman (M.), Dorothea H. Suttie (M.), Lydia I. H. Torrance (M.).

The following have passed in Medical Jurisprudence and Public Health of the fourth professional examination (New Medical Ordinance):—

J. W. W. Baillie, J. E. Bannen, W. M. Cameron, M.A., R. Cunningham, D. Heard, F. W. Hebblethwaite, G. M. Hetherington, H. E. Hollis, J. R. R. Holms, J. N. Jamieson, M.A., K. M'Alpine, N. MacKillop, J. M. Mackintosh, M.A., H. Robertson, M.A., H. B. Sergeant, A. W. Smith, J. T. Wylie.

WOMEN.

Janetta M. Alexander, W. J. Crawford, Margaret H. Glen, A. J. Marshall, May I. T. Reid, Marion Watson, Mary M. Weir, M.A.

The following have passed the Medical Jurisprudence and Public Health of the third professional examination (Old Medical Ordinance):—Alex. G. Brand, John M. Clark, William H. Gordon, M.A., E. G. S. Hall, Tom J. Honeyman, Andrew B. M. Lang, M.A., Arthur D. C. M'Gowan, Alex. B. Stitch, B.Sc., John A. White.

Note. Students under the Old Medical Ordinance who have not previously passed in Pathology will note that a pass at this time in Medical Jurisprudence is conditional on their also undergoing the present examination in Pathology.

DISTINCTION LIST.

The following have passed with distinction in Medical Jurisprudence and Public Health:—William M. Cameron, M.A., James N. Jamieson, M.A., Andrew B. M'Alpine, M.A., James M. Mackintosh, M.A., Mary MacL. Weir, M.A.

Degrees of M.B. and Ch.B.—The following have passed the Fourth (Final) Examination:—William D. Allan, John Alston, William Baird, Christina B. Buchanan, Duncan Cameron, Joseph Chalmers, Douglas H. Coats, William K. Connell, Alexander F. Cook, Archibald S. Cook, Walter G. Cook, John N. Cruickshank, Andrew Davidson, Jane B. Davidson, John Dunbar, James B. Fisher, Matthew M. Frew, Thomas R. Fulton, William H. Gibson, Jessie C. Gilchrist, John Glaister, James S. Kinross, George Kirkhope, William J. B. Lavery, Robert Lindsay, M.A., Dorothy M'Cutbin, James W. Macfarlane, John MacInnes, Keith S. Macky, Duncan M'Laren, Elizabeth S. Martin, Frederick R. Martin, James M. Matheson, William W. Morrison, Alexander Morton, William O'Brien, James A. Paterson, Thomas S. Paterson, James H. Paul, M.A., B.Sc., William J. Poole, Thos. J. D. Quigley, James Richardson, Alexander W. Ritchie, George W. Ronaldson, Mary H. Routledge, Mary I. Sinclair, Jane Stalker, William M. Stewart, John L. Torley, Robert S. Weir, Clive A. Whittingham, Marion B. D. Wilson.

The following have passed with distinction:—In Surgery and Clinical Surgery—George Kirkhope. In Medicine and Clinical Medicine—Jane Stalker. In Midwifery—William D. Allan, Joseph Chalmers, John Dunbar, Mary H. Routledge, Clive A. Whittingham, Marion B. D. Wilson.

Scotch Triple Qualification Passes.

THE examinations of the Board of the Royal Colleges of Physicians and of Surgeons of Edinburgh, and

Royal Faculty of Physicians and Surgeons of Glasgow were concluded at Edinburgh on the 7th inst., with the following results:—

First Examination.—The following candidates passed:—Thomas A. du Toit, Robert B. Forgan, Wm. H. Kerr, Richard F. Kerr, Lizzie R. Clark, Mayberry H. Carleton, Jung B. Singh, and George C. Field. Biology.—Peter E. Malloch. Chemistry.—John Murray and Andrew W. Smith.

Second Examination.—The following passed:—Albert E. Hempleman, Reginald E. Hopton, Arthur S. Hughes, Eduard L. Adendorff, Rebecca Goodman, John K. Steel, and William Gibb. Anatomy.—Hugh W. Howatson. Physiology.—Jacob J. van Niekirk, Gordon S. Woodhead and James F. Cook.

Third Examination.—The following passed:—Cecil V. Samwell, Ernest E. Bronstorff, George P. de Silva, Henry Shaw, Andrew L. Meek and Christopher R. C. Moon. Pathology.—Mahmoud A. K. Mofreh, Eliza J. Stuart, Martin Fernando and Donald Stewart. Materia Medica.—Daniel C. Howard.

Final Examination.—The following candidates having passed the final examination were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:—Zachariah A. Green, James E. Ainsley, John C. Bedwell, Harold C. A. Haynes, Bertram C. Haller, James Byrne, James V. R. Rohan, Salamon J. Abrahams, James Blackburn, Charles Harris, Andrew Caston, and Robert C. Wilson Spence. Medicine.—Stanley W. Hoyland. Surgery.—John J. Curtin. Midwifery.—John Adami and John J. Curtin. Medical Jurisprudence.—John H. Blackburn, Reginald V. Clarke, Charles G. Book, William McElroy, and Maurice A. White.

University of Aberdeen.

The following is a list of candidates who have passed the necessary examinations, and received degrees during March:—

Degree of Doctor of Medicine (M.D.).—Archibald D. Pringle, M.B., Mental Hospital, Observatory Road, Cape town. "Commendation" for Thesis.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—With Second Class Honours: *Robert D. Lawrence, M.A., Aberdeen, **Arthur G. Reid, Aberdeen.

Ordinary Degree: William Alexander, M.A., Kemnay, Aberdeenshire, John Anderson, Croy, Gollanfield, Inverness-shire, Mary A. Chalmers, M.A., Aberchirder, Banffshire, Arthur J. Hawes, Woodbury, Lowestoft, Arthur A. Hearne, Kingston, Jamaica, Stanley Henry, Elgin, Eva C. Ironside, M.A., Huntly, Burjorji S. Kanga, Bombay, Thomas S. Law, Aberdeen, Arthur A. Mackenzie, M.A., Turriff, Charles W. Macpherson, M.A., Sunnybank, Dufftown, William J. Moir, Allavane, Banff, *Thomas O. Robson, Aberdeen, Albert E. B. Sim, Aberdeen, Forbes Simmers, Hatton, Cruden, Aberdeenshire. *Passed Fourth Professional Examination with "Distinction." **Passed Fourth Professional Examination with "Much Distinction."

NOTICES TO CORRESPONDENTS,
BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 2s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

F. M. S.—On inquiry we find that all the Freemasons' Lodges in connection with the medical schools have continued their meetings since the outbreak of the war.

"A SISTER."

Visitor (at private hospital): Can I see Lieutenant Barker, please?

Matron: We do not allow ordinary visitors. May I ask if you are a relative?

Visitor (boldly): Oh yes! I'm his sister.

Matron: Dear me! I'm very glad to meet you. I'm his mother!—*Punch*.

AN ADVANTAGE OF WAR?

The medical officer of Carnarvon states that the children of soldiers are to-day better clothed and better fed than they have been at any time during the past fifteen years.

DOCTORS FROM THE LABOUR EXCHANGE.

Among the posts advertised as vacant in the window of a London Labour Exchange on April 3rd was one for a lady doctor.

EX AQUALI.—In addition to the various antiseptic methods employed at the front, septic wounds are now being treated by a continuous electric current of 30 volts and 30 amperes.

NO EIGHT HOURS DAY.

It was stated at Clerkenwell County Court that a doctor, with an artificial leg, was now standing for twelve hours a day at the operating table.

PERTH PANEL WORK.

In 1915 one-third of the insured population in Perth received treatment, while each patient was seen by the doctor six times on an average. It is pointed out that three prescriptions which cost 6d. before the war had increased in cost to 1s. 6d., 2s. 7d., and 3s. 4d. respectively.

PHARMACOLOGIST.—It is against our rule to recommend any particular consultant. Our correspondent might seek advice from one of his medical customers.

THE CONSCIENTIOUS OBJECTOR.

In the correspondence column on this subject in our last issue, for "patriotic principle" in Dr. T. Clave Shaw's letter read *petitio principii*, which is the logical term for begging the question.

SCHOOLCHILDREN'S GIFT.

A MOTOR-AMBULANCE, the gift of the schoolchildren of Wandsworth, has been presented to the Mayor of Wandsworth for the use of the 13th East Surrey Regiment, raised by him some time ago. The ambulance is the first in England to be fitted with heating apparatus.

Meetings of the Societies, Lectures, &c

WEDNESDAY, APRIL 12TH

HUNTERIAN SOCIETY (1 Wimpole Street, W.).—9 p.m.: Adjourned Annual Discussion on the Relationship of the Medical Profession to the State and the Community. Dr. H. J. Cardale, Dr. B. A. Richmond and others are expected to take part, and Dr. F. J. Smith will reply.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of Lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes):—5.30 p.m.: Professor A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days, and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

THURSDAY, APRIL 13TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Mr. J. E. R. McDonagh: The Rationale and Practice of Chemo-Therapy. N.B.—Fellows and Members of other Sections are invited to attend and to take part in the discussion.

FRIDAY, APRIL 14TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of Lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes):—5.30 p.m.: Professor A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days, and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANESTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Paper: Dr. M. S. Pembrey and Dr. F. E. Shipway: Observations on the Influence of Anesthetics on the Body Temperature. Demonstrations—Dr. F. E. Shipway: Apparatus for the Administration of Warm Anesthetic Vapours. Dr. Harold Low: Apparatus for the Intratracheal Insufflation of Ether. Dr. F. E. Shipway: Apparatus for the Intratracheal Insufflation of Ether. Captain C. T. W. Hirsch: Modification of Waller's Chloroform Inhaler.

CENTRAL MIDWIVES BOARD (Caxton House, Westminster, London, S.W.).—11 a.m.: Special (penal) meeting at Caxton Hall, Caxton Street, S.W.

Vacancies.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £100 per annum, with apartments and rations. Applications to S. J. Leonard, Clerk. (See advt.)

Highfield Military Hospital, Liverpool.—Assistant Resident Medical Officer. Salary £300 per annum, with rations, furnished apartments and resident allowances. Applications to the Clerk to the Select Vestry, Brownlow Hill, Liverpool.

Derbyshire Royal Infirmary.—House Physician and Casualty Officer. Salary £200 per annum, with board, residence, etc. Applications to E. Forster, Secretary.

Cambridgeshire Asylum, Fulbourn, near Cambridge.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Doncaster Royal Infirmary and Dispensary.—House Surgeon. Salary £250 per annum, and board, lodging, and washing. Applications to the Hon. Secretary.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Hon. Secretary, Infirmary, Bury, Lancs.

Birmingham General Dispensary.—Resident Medical Officer. Salary £250 per annum, with furnished apartments, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary, 32 Union Street.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with board, residence, and washing. Applications to the Secretary.

Putney Hospital, Lower Common, Putney, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry. Applications to the Hon. Secretary, at 198 Upper Richmond Road, Putney, S.W.

Appointments.

GRANT, J. DUNDAS, M.D. Edin., F.R.C.S. Edin., Surgeon in Charge of the Ear, Throat and Nose Department of the New Zealand Military Hospital, Walton-on-Thames.

MAINS, J. H., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Clackmannan District of the county of Clackmannan.

MARTIN, ROBERT COLLINS, L.R.C.P. Lond., M.R.C.S., Medical Officer for the No. 1 District by the Bristol Board of Guardians.

MORGAN, ALBERT THOMAS, L.S.A. Lond., M.D. Brux., Public Vaccinator for the Ashley District by the Bristol Board of Guardians.

Births.

COX.—On April 9th, at 8 Ellerdale Road, Hampstead, to Dr. and Mrs. R. J. H. Cox, C.M.S., Bannu, N.W.F.P., India—a daughter.

JACKSON.—On April 3rd, at "Harland Rise," Cotingham, East Yorks, the wife of Dr. T. C. Jackson, of a son.

Marriages.

CLARKE—WAKELING.—On April 5th, at Christ Church, Shooter's Hill, Roger H. Clarke, Surg. Prob., R.N.V.R., son of the late Edward Nalder Clarke and Mrs. F. J. Powell, to Marjorie Blanche, elder daughter of Mr. and Mrs. H. Wakeling, of Chesterton, Cambridge.

HARTY—CLARK.—On April 8th, at All Saints' Church, Notting Hill, John Percy Ingham Harty, M.B., F.R.C.S., Captain, R.A.M.C. (T.), second son of the late J. P. Harty, J.P., Cork, and Mrs. Harty, Bristol, to Helen Dorothy, second daughter of Mr. and Mrs. J. G. Clark, of 17, Ladbrooke Gardens, W.

JOHNSTONE—GRAHAME.—On April 4th, at St. Columbia's, S.W., Thomas Johnstone, M.D., M.R.C.P., of Harrogate, youngest son of the late Thomas Johnstone, Beech Hill, Annan, to Agnes Mary Grahame, of Ripon, daughter of the late John Anthony Grahame, of Westminster and Sussex Gardens, W.

LEECH—BARKER.—On April 3rd, at Leonard Stanley, Ernest Bosdin Leech (of Manchester), M.D., Captain, R.A.M.C., to Mary, daughter of the late Rev. H. Walder, of Jamaica, and widow of Robert Barker, of Marple.

LUCAE—MCKAIL.—On April 3rd, at St. James's, W. Hampstead, Captain Reginald Blockley Lucas, M.B., M.S., R.A.M.C., eldest son of Mrs. A. R. B. Lucas, of Adelaide, S.A., to Cecily Helen, only daughter of Mrs. John McKail.

SMITH—ACKERLEY.—On April 6th, at St. Matthew's Church, Surbiton, Austin Nimmo Smith, Captain, R.A.M.C., son of the late Rev. R. Nimmo Smith, LL.D., and of Mrs. Nimmo Smith, to Muriel Alice, daughter of Dr. R. Ackerley, of Llandrindod Wells.

Deaths.

BARKER.—On April 8th, of acute pneumonia and nephritis, Colonel A. E. J. Barker, A.M.S., in his 66th year.

CROSBY.—On Friday, April 7th, after a few days' illness, Sir Thomas Boor Crosby, Alderman for the Ward of Langbourne, in his 86th year.

HAWKSLEY.—On April 4th, Walter Linney Hawksley, Major R.A.M.C., eldest son of the late Dr. and Mrs. Hawksley, of Southport, aged 33 years.

PHELPS.—On April 8th, at Baxter Gate, Loughborough, Philip Phelps, M.R.C.S. Eng., F.R.C.P. Edin., L.M., aged 63.

SIMPSON.—On April 6th, at Edinburgh, Alexander Russell Simpson, Kt., M.D., D.Sc., LL.D., Emeritus-Professor of Midwifery in the University of Edinburgh, in his 81st year.

STRICKLAND.—On March 25th, at Naringla, Craneswater Park, Southsea, Fleet Surgeon Charles C. Strickland, R.N. (retired).

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, APRIL 19, 1916.

No. 16.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

LETTERS on the subject of the Central Medical War Committee continue to reach me in considerable numbers. The writers all express their cordial approval of the attitude which the MEDICAL PRESS AND CIRCULAR has adopted; some of them ask questions, but not one of them expresses dissent from the views which have been reflected in these columns. This last statement requires this saving clause. From Ireland have come some very vigorous protests, dictated by the mistaken assumption that my remarks concerning the Central Medical War Committee included reference to the body which is recruiting and enrolling the medical profession in Ireland. I thought that two disclaimers on this subject would be sufficient, but in that I was apparently mistaken. To all whom it may concern, then, I say, for the third time and last time, that my criticisms and remarks concerning the Central Medical War Committee referred to that body and to that body alone. It was born of the British Medical Association, it sits at 429, Strand, London, W.C., and it has for its Secretaries, Dr. Alfred Cox and Mr. Bishop Harman.

Some Questions. SOME of the questions which I have been asked arise from a careless reading of what I wrote; but one of them, which recurs with a disconcerting frequency, derives from an equally disconcerting accuracy. This question demands to know what I meant by saying that medical men were specifically excluded from the operation of the Military Service Act? Well, let me at once admit that I was misinformed when I made that statement. Medical men are not so excluded, save in a very limited sense, and that sense is administrative only; it is not legislative. Under the Act the authorities may call up all medical men of military age to serve as combatants; but they cannot call up medical men to serve as medical men. A doctor may join as a combatant, but if he wishes to join *quâ* medical man, then he must enrol with the Central Medical War Committee. Either that, or he can apply directly to the Medical Authorities at the War Office.

THE Central Medical War Committee of (429, Strand: Secretaries, Dr. Alfred Cox and Mr. Bishop Harman) remains the unsatisfactory body that it was. It is true that an Advisory Committee appointed jointly by the Royal College of Physicians of London and the Royal College of Surgeons of England is now in existence; and there is no doubt that this Committee will serve to give confidence to the profession. That the newly-appointed Committee has not very much confidence in the Central Medical War Committee (429, Strand: Secretaries, Dr. Alfred Cox and Mr. Bishop Harman) is evident from the following resolution passed on March 17th at a Comitia of the Royal College of Physicians. I quote from the *Lancet* of March 25th, p. 682. The italics are mine. "That this College is willing to join the Royal College of Surgeons in forming an Advisory Committee to give advice to the Government in relation to medical practitioners in the metropolitan district required for service in the Army, and also to advise on cases of special difficulty elsewhere in England and Wales. *Such advice to be communicated through the Central Medical War Committee, without alteration, to the Government departments concerned.*"

The Age Limit. A QUESTION which I have been asked, to which I can find no satisfactory reply, is this: "Who raised the age for medical officers in the Army from the 40 years of the Military Service Act, to 45?" I presume it was the Central Medical War Committee (address and secretaries as above), and I should be interested to know by whose authority this was done. To summarise the answers which I might have to give if I replied to each enquirer in detail, let me put the matter thus (some of it is repetition, but apparently it is very necessary repetition): The enrolment pledge is given, not to the King, or the Government, or the War Office, but to the Central Medical War Committee (429, Strand: Secretaries, Dr. Alfred Cox and Mr. Bishop Harman). The invitation to men over 40 so to enrol is purely gratuitous, and cannot possibly be enforced; nor can the invitation to married men under 40 be enforced. In the case of specialists, members of the staffs of hospitals, metropolitan or

provincial, or anyone else not ordinarily circumstanced, care should be taken to ensure that the special features shall be duly considered before the individual is induced to enrol. In principle, enrolment is a good and even a necessary thing, but so long as the ultimate decision rests with the self-appointed Committee which sits at 429, Strand, and has for its Secretaries Dr. Alfred Cox and Mr. Bishop Harman, so long will members of the profession who are not members of the British Medical Association be held excused for declining to be drawn into the net.

Mr. H. A. BARKER ought to be very much gratified by the testimonials to Sir Arthur Markham and his skill (they are surely unsolicited) which continue to burst forth from people—presumably beneficiaries—speaking in Parliament and writing in the Press. Sir Arthur Markham has been beating the drum in Parliament; the Editor of *Truth* has taken up the parable; and Mr. H. G. Wells has contributed to the *Daily Mail* a deplorably stupid letter on the subject. Sir Arthur Markham need not, of course, be taken seriously; his recent public appearances have not added to his credit, and this attempt to obtain War Office recognition for an unqualified practitioner will scarcely rehabilitate him in the estimation of sensible people. Mr. Tennant's very proper and very pertinent reply was that, if he were to allow an unqualified practitioner to operate on soldiers, the House of Commons is the first place where he would be arraigned and denounced. Let us hope that the House will continue in this spirit of sanity.

"TRUTH" is a paper which in former times used to be conspicuous for its sturdy and independent commonsense, and I am bound to admit that it still exhibits these qualities in a general way. In the present instance, however, though the sturdiness and independence may be there, the commonsense is not. What, for example, could be more nonsensical than the proposal contained in the following paragraph?—

"One remedy for this state of things is that there should be a power outside the medical faculty of granting the formal qualification which entitles a man to be registered. For example, the power might be given, under suitable safeguards against abuse, to the Home Secretary or the President of the Local Government Board. It would not be difficult to frame and pass an Act for this purpose, even at the present time."

A much simpler remedy for "this state of things" would be for Mr. H. A. Barker to obtain the necessary licence to practise surgery. In the case of such a heaven-sent genius, the examinations—which, after all, demand the very minimum of knowledge—could present no difficulty whatever. Why on earth does he not pass them?

BUT the gem of the literary contributions to this silly subject is from the pen of no less an author than Mr. H. G. Wells' contribution. Mr. H. G. Wells, who, under the title of "The Medical Muddle," writes the following letter to the *Daily Mail*:—"Of one trade union at least the Government is too afraid to dare to use non-union skill, and that is the medical trade union. Mr. H. A. Barker, the bone-setter, has offered his services free to the country, and they have been rejected. There is no doubt in my mind that this refusal means that a great number of men will be unable to go to the front who might otherwise do so, and that there will be a number of men permanently and needlessly disabled for life. All to the greater glory of that ancient guild of medicine, which nevertheless lets

loose a horde of 'qualified' ignoramuses upon our population. This is a matter upon which I have special knowledge; I know the atrocious incapacity of the general practitioner, and I know the peculiar skill of Mr. Barker. If it were not for him, if I had trusted to the sort of man the medical profession endorses, I should be an ailing cripple to-day. Clyde tactics are an intolerable disloyalty in these days of urgent need. The Army medical authorities have no more right to waste Mr. Barker's skill and patriotism in this fashion, on a purely technical point, than malcontent strikers have to keep good machinery idle. They deserve a common goal."

THIS is a very fair specimen of the kind of irrational and senseless tomfoolery into which an able man may be betrayed when he barges into an intricate domain with nothing better than impatience, ignorance, and prejudice to guide him. If Mr. H. G. Wells knew anything whatever about matters medical, he would not make the egregious mistake of stating that the medical profession is, in any sense whatever of the term, a trade union. For that is precisely what it is not. Its members are made to toe an examinational line, not for their own protection, but for the protection of the public; and the toeing is imposed upon them, not by the other members, but by the statute. Having expended five years of his time and a considerable sum of money in toeing the line with success, a doctor is not in any way protected by law from the competition of the free-lance; who, having escaped the mill of dissecting-rooms, laboratories, lectures, wards and examinations, manages to persuade an impressionable and credulous public that he has been endowed from on High with knowledge without study, skill without practice, and the power to perform miracles without the previous laying on of hands.

MR. H. G. WELLS asserts that this "ancient guild of medicine lets loose a horde of qualified ignoramuses upon our population." Well, for the sake of argument, let us suppose that such is the case, which in reality it most emphatically is not. Is it contended that the lot of the suffering population will be improved by abolishing the necessity for qualification? Is a man any more of an ignoramus for having passed examination tests? If not, what is Mr. H. G. Wells' remedy? Mr. Wells goes on to say that the Army medical authorities have no right to waste Mr. Barker's skill. How do the said authorities know that Mr. Barker is endowed with this exceptional skill? He appears never to have subjected himself to any examination. Had he done so, with this extraordinary skill, he surely would have passed. There is therefore no official evidence upon which to rest any confidence in this alleged skill. The only sort of testimony on the subject is the enthusiastic testimony of such as Sir Arthur Markham, Mr. H. G. Wells, the Editor of *Truth*, and some celebrities who write from Upper Tooting to the *Star*. Where health is concerned enthusiasm is a very poor substitute for knowledge; nevertheless, it is on showing such as this, that the law is to be altered, the necessity for a diploma to be removed, and unqualified practitioners are to be turned loose on the Army. Was there ever such preposterous balderdash?

THE name of Wittenberg will go down to posterity as that of the foulest and most loathly crime which has ever disgraced the annals of medicine, and the name of Aschenbach as that of the most callous, cowardly and contemptible monster who has ever dishonoured the title of doctor.

SINAPIS.

OF ARTERIAL DISEASE.

THE purposeful artistry which Nature everywhere displays, is nowhere better exemplified than in the distribution of the conduits which carry the blood from the centre to the periphery. The physiological integrity of the conduits is almost as essential to freedom of soul and body as the purity and sufficiency of the blood itself. With the grosser composition of the circulating fluid we are familiar; of its subtle essences we know nothing. To what extent and through what agencies it brings gradual destruction upon its conduits is a question which has occupied some of the best minds in all ages, and is still unsolved. With the grosser composition of the walls of the arteries we are also familiar. Concerning adventitia, media and intima there is anatomically and physiologically little that we do not know. But no sooner do these enter the domain of pathology than we are undone. In spite of much laborious work, the riddle of arterial disease still awaits solution.

Sir Clifford Allbutt's book (a), which more perhaps than any other, has suffered from being a war baby, is a contribution to the study, if not to the elucidation, of the many fascinating problems which this question englobes. The examination and discussion of these problems could not have been undertaken by anyone more suited to the task than the learned Professor of Physic at Cambridge; for, almost alone among present-day writers, he is gifted—in a very high degree gifted—with the special qualities which render such a discussion tolerable. To say that the discussion is exhaustive would be more than partially to conceal the fact that it is discursive. Discursive it is, but that does not prevent it from being delightful. To say that its conclusions are hesitating would be true, but the hesitation is essentially that of the true scientific spirit. Scholars and intellectuals are always inconclusive, and not infrequently ineffectual: their deductions are born of a higher sphere, are reared in a more rarefied air, than the dogmatisms of lesser minds. It is only to the ignorant, in pathetically fruitless search of certainty, that inconclusiveness appears to be a vice. In a text-book it is insufferable; but in an essay it is often a tributary to the full stream of pleasure. When you have read this particular essay you close the second volume with the satisfaction of having read all that can possibly be written on the subject of arterial disease, but the satisfaction is leavened with the chastening conviction that you know nothing whatever about it. And yet you are delighted. In all good writing—and Sir Clifford Allbutt writes nothing that is not superlatively well written—there is a sense of reserve. The artist in words seems to say a great deal, and yet, to the discerning eye, he obviously says less than he would like to say. He displays the church, but the steeple of his experience-ripened thought is more than half-reluctantly concealed. On occasions all too rare

(a) "Diseases of the Arteries including Angina Pectoris," by Sir Clifford Allbutt, M.A., M.D., F.R.C.P., F.R.S., Regius Professor of Physic in the University of Cambridge. 2 vols. London: Macmillan and Co., 1915 (price 30s. net).

does he take his reader into his real confidence. He always appears to be doing so, but that is only a part of the charm of good breeding and the grand manner. Back, as the Americans say, back of all this seeming discursiveness which would suppress nothing which others have contributed; back of this baffling inconclusiveness, there sits a conclusion which is never quite revealed. There is a veil past which we cannot see, and yet we do not repine: for the grand manner in matters medical is full of compensations, if only for its contrast to the shallow mechanical pronouncements and dreary illiteracy of the ordinary text-book.

Angina pectoris is to a very large extent a function of arterial disease, and the last 200 pages of the second volume of Sir Clifford Allbutt's book are devoted to a consideration of this "appalling and picturesque disease," as Sir Richard Douglas Powell calls it, "about which a certain glamour has been cast by the many noble and distinguished lives it has stricken down." From a perusal of these 200 pages you arise puzzled, perplexed and distracted, but with a pleasing sense of stimulation, and a consciousness of literary enjoyment which includes wonder. The chapter on the "Causes of Angina Pectoris" (page 249) begins with these words: "Angina is by no means unknown in the aged and decayed, but its greater prevalence is at a somewhat earlier stage, in the years of senescence; in senectus, not in senium." On page 285 there is the following passage: "If now we turn from the site to the degrees of pain, I would urge that, if in one extreme the pain is ruthless, such that the patient feels as if 'the life were being squeezed out him,' if, as no other pain, it racks the very depths of anguish, and in its reiterating paroxysms of torture and dismay seems to be more than flesh and blood can bear, and if in the severest cases a 'status anginosus' may bait the sufferer, making him as one of the older writers says, 'furibundus,' for hours or for days—for days in one of Heberden's cases—yet in other cases its passage may be so light and transient as only too often to escape serious attention, yet, even in these minor skirmishes, it brings with it a peculiar malice, a warning innermost touch; incomprehensible, vaguely startling." Such phraseology is magnificent, so magnificent that we are apt to lose sight of the substance in our admiration of the form. It is caviare of a very high refinement, and as such, may all too easily prove its own undoing. For while illuminating, it seems to obscure; and while encouraging, it disheartens.

As in arterial disease then, so in angina pectoris, we are filled to overflowing with the potential details, we are indeed satiated therewith, but the garment of our knowledge is still depressingly shapeless, without form and void. The elements of this "appalling and picturesque" jigsaw are all here, vaguely gyrating under our prentice hands, but the master hand which is to introduce balance, proportion and perspective, alas! it still tarries.

L. B. W.

Brixton Dispensary is appealing to residents to send along old medicine bottles.

CURRENT TOPICS.

Heliotherapy.

IN our struggle towards the light it is possible that we may have forgotten the sun. Immersed in our labour, beset with a myriad details, we have ceased to raise our heads for even a moment. Years have rolled on into centuries, therapy has succeeded therapy, infections have disappeared or become modified, but the same ceaseless battle beats about the world, the conflict with suffering and disease. And throughout the æons the untiring, patient, all-embracing, all-sufficing sun has risen and set, has passed through his eternal wheeling circles in the æther, a great neglected doctor, slighted, but enduring his slight in serenity and silence, awaiting his hour.

To-day we are told that he may be about to come into his own. In Switzerland and in America a variety of lesions perish under his penetrating eye. As a therapeutic agent in dermatology, the X-rays pale beside his effulgence. Cervical adenitis, tuberculosis, neurasthenia—nay, even in the healing of wounds—his unimpaired and unhindered activities act like a charm. It is permissible to us in the present age of remedies, when "each minute teems a new one," to be sceptical; but perhaps in this single instance we may be entirely wrong. That so central and dynamic a force—so conserving a medium—to which the void and the planets instinctively respond, should have an inhibitory power upon disease is not illogical. It is only one expression of the eternal fact, human and divine, that darkness of necessity perishes before the light.

Cultivation of Medicinal Herbs.

MR. E. N. HOLMES, curator of the Pharmaceutical Society's Museum, gave a lecture on the cultivation of medicinal herbs in Great Britain at the headquarters of the Royal Horticultural Society on April 11th. He said that hitherto we had depended mainly on Germany and Austria for our supply of medicinal herbs, and it was difficult to understand why there should be any necessity to import herbs that grew wild in this country. It seemed absurd to import coltsfoot by the ton when every clayey railway bank or heavy waste-ground was covered with the plant. In Germany children were taught to recognise and collect medicinal herbs that grew near their homes; these were dried in small quantities in sheds or attics, and probably finished off in farmhouse bread ovens after the removal of the bread. In the absence of any system of collection in this country vast quantities of valuable herbs were left to waste. He showed how we could become independent of Germany for our supplies of two of the most valuable drugs known—namely, belladonna and foxglove. Belladonna was found in twenty-eight British counties. An enormous increase in the yield could be obtained if the head gardeners on estates where it grew wild were instructed to distribute, in April, all seedling plants to other positions in the same woods, since the seedlings were often too crowded. If this were done and the plants cut at the proper time and sold to the agents of wholesale drug firms, there would be

no need to import belladonna, and it was quite possible that there would be a sufficient supply even for export to those of our Dominions where the climate and local conditions prevented its successful culture. There was an enormous quantity of foxglove growing wild in damp, hilly woods in this country, and if large landowners, whose soil was silicious, would give instructions to their head gardeners to plant out the young plants or scatter the seed in autumn in fresh localities there would be no necessity to import foxglove from the Continent. Speaking of the cultivation of culinary herbs, such as sage, mint, angelica, basil, thyme, and other sweet herbs, he stated that the only way to make it pay was to increase the quantity of any herbs that suited the soil, dry it, and forward it to a central warehouse. The lecturer urged that a tariff should be imposed on imported medicinal herbs, otherwise it would be impracticable by most of those who had begun their cultivation in this country in war-time to reap a benefit for their outlay.

The Full Life.

THE old proposition that we eat to live, and the denial of the reverse, are alike commonplaces. If we phrase it rather "man works to live, but does not live to work," we fear that a democratic support may be lacking. Work for work's sake has burnt itself into the human brain as something worthy of admiration and emulation. Nowhere has it held such spacious court as in the American mind—heretofore. Yet out of America now comes a cry of protest. In the year 1880, twenty-one per 10,000 people succumbed to the cardio-vascular syndrome so strongly associated with mental hyperactivity and anxiety. In 1910 the figure became 39, 50 per cent. higher than that of England and Norway to-day, from the same cause—mental strain and tension. Let us be wise in time, if it so be we may. Our destiny, physiological and spiritual, is not to be fulfilled merely by cramming as much specialised effort as possible into the twenty-four hours consecutively. There are relatives, friends, the air and the earth. The unfortunate element is, however, that our relaxations under such circumstances are of themselves of a condensed and hastened nature. What we lack is leisure—the sly schoolboy humour of Horace, which faintly shrugs its shoulders, bids professional cares begone to the devil, whence perchance they came, and ejaculates:—

"Dulce est desipere in loco."

Surgery or Pruning.

SOMETIMES we feel that there is much to be said for the popular conception of a surgeon—a man who rejoices in the sight of blood, takes pleasure in cutting off a limb, whose mind is of a type but little removed from that of a butcher. This idea is widespread amongst the less completely educated of our public. It can hardly be without foundation. All they know of the surgeon is that after his ministrationsome relative or friend returns home minus a diseased limb or a swollen goitre or a cancerous breast. What is a surgeon but one who hacks away these troublesome appendages? We wonder are they altogether wrong. Is there never a time when we choose the simpler way of removal rather than the difficult and tedious path of preservation? There are few of us who do not view with some distaste the necessity for the amputation of a limb or other mutilation of the symmetry of the body, but are we always so anxious to preserve the unseen and hidden things of nature? Hysterectomy is so much easier than a troublesome myomectomy, a tonsillectomy so much the most obvious way of curing tonsillitis. We are glad to see a plea for

the conservative treatment of tonsils by Dr. Hudson-Makuen, of Philadelphia, in a recent number of the *New York Medical Journal*. He maintains that time and again the opening of a pocket in a tonsillar crypt will give as good a result as the complete removal of the gland. His criticism is that the latter procedure is often unnecessary, and may be even harmful, although the immediate results will appear satisfactory. The radical operation, he says, ought to be the exception rather than the rule, and "the man who tonsillectomies a dozen or fifteen patients in a single afternoon had better spend his afternoons in an abattoir."

Soldiers' and Sailors' Dental Aid Fund.

THE Committee of the above Fund informs us that its work is terminated as from March 11th, 1916, Sir Arthur May, K.C.B., Medical Director-General of the Admiralty, has informed the Committee that the Admiralty has now decided to supply artificial teeth, if necessary, to all sailors and recruits for the Navy.

Sir Alfred Keogh, K.C.B., Medical Director-General at the War Office, has informed the Committee that the War Office has decided to supply artificial teeth, if necessary, to all Overseas men, and further, as he does not consider it necessary for the Home-service Army to have artificial teeth, he can no longer allow the Fund to use the words, "Authorised by the War Office."

In view of these statements the Committee has no alternative to the course it has taken, though it much regrets that Sir Alfred Keogh should have withdrawn his sanction of the work done on behalf of the Home Army.

The Committee, nevertheless, can congratulate itself upon the success of its efforts on behalf of the two services and the appreciation of its work constantly expressed by the Authorities.

The Secretary, Miss Fletcher, draws our attention to the following facts:—

Since its inception, the Fund has dealt with over 11,000 fighting men, and it has done this without paying (a) any salaries, (b) any rent, rates or taxes, (c) and, owing to the great patriotism and courtesy of the Press (together with members of the Fund paying for small advertisements), any expenses in advertising.

Since November, 1915, the Committee alone have paid for all the artificial teeth for the home-service men. She points out that the War Office now gives artificial teeth to all the Overseas men, and that the Admiralty are now giving artificial teeth to all the sailors and recruits for the Navy.

The Dangers of Gratuitous Work.

THE generous way in which the medical profession of the United Kingdom has given its services to the nation in the past two years is not without its dangers to our future position. What has been given as a free gift is likely to be accepted as if it were a right. In the Red Cross Hospitals our wounded are being treated gratuitously by surgeons and physicians; in the general hospitals the medical staffs are giving their services without fee or reward. From the economic point of view we fail to find any justification for this. The care of the wounded soldiers and sailors is just as much a charge on the State as the feeding and maintenance of the men in the field and on the seas. But no one expects the baker or the clothier to supply his goods gratis as a contribution to the State. Medical men, however, must be careful that their free-will offering remains a free-will offering, and that those who are not in a position to offer their services gratis are not subjected to attack for exercising their

rights. A scandalous instance of abuse of medical men for exercising their undoubted rights in this matter has just occurred in Belfast. It appears that the Belfast Guardians have given hospital accommodation to a number of wounded soldiers, and that the necessary treatment has been given by the workhouse medical staff. The sum paid by the military authorities to the Guardians is admittedly more than is required for the maintenance of the patients, and in those circumstances the medical staff has made the natural demand that they should get some remuneration for their services. The payment asked is trifling, but for this entirely equitable demand they have been subjected to gross abuse and criticism, chiefly on the ground that "other doctors—the most eminent men in the city" were doing similar work without pay. If our generosity is to be made a justification for refusing our rights, we may be forced to consider whether our generosity is wise or just.

Cardio-vascular Complications in Paratyphoid.

DR. MINET, at the Society of Medicine, gave an account of 19 cases of paratyphoid infections, which showed that paratyphoid, just like typhoid infections, may affect the cardio-vascular apparatus. They may cause phlebitis of the "phlegmasia alba dolens" type, often myocardiac insufficiency, and even chronic myocarditis. This proves how erroneous is the idea that paratyphoid infection is merely an attenuated typhoid infection.

PERSONAL.

DR. FREDERICK TAYLOR has been re-elected President of the Royal College of Physicians.

SIR FREDERICK W. HEWITT, M.D., M.V.O., Anaesthetist to the King, left £35,378.

DR. NORMAN MOORE has been re-elected a representative of the Royal College of Physicians on the General Medical Council.

DR. DAVID HOOPER, formerly Curator of the Economic and Art sections of the Indian Museum at Calcutta, and a collaborator of the late Brigade-Surgeon Dymock in the compilation of "Pharmacographia Indica," has been elected president of the British Pharmaceutical Conference. Dr. Hooper was at one time quinologist to the Madras Government, and in 1907 was the recipient of the Hanbury medal.

DR. LAWRENCE BLANDFORD, who has been promoted Assistant Director of Medical Service with the rank of temporary colonel in the First Mounted Division, is a well-known Tees-side medical man, and the only son of Dr. Blandford, of Stockton. He was prominently identified with the Territorial Force, and on mobilisation he was called to the staff of the Northumbrian Division as sanitary officer. When the Division proceeded to the front last April he was appointed Deputy-Assistant Director of Medical Service.

LIEUTENANT-COLONEL ROBERT JONES, R.A.M.C. (T.), lecturer on orthopaedic surgery at Liverpool University, has been appointed Inspector of Military Orthopaedics. The duty of the inspector will be to supervise the treatment in various military hospitals and sections of hospitals set apart for orthopaedic cases, the first of which will be the Hammersmith Military Hospital. The buildings, consisting of the Hammersmith Infirmary and Workhouse, will hold about 800 men, and there will be departments for whirlpool baths, massage, and other forms of special treatment, in addition to a large gymnasium. The British Red Cross Society is helping to provide the equipment.

CLINICAL LECTURE

ON

TWO CASES OF MALIGNANT DISEASE OF THE BODY OF THE STOMACH.

By WILLIAM RUSSELL, M.D., F.R.C.P.Ed.,

Professor of Clinical Medicine in the University, and Physician to the Royal Infirmary, Edinburgh.

THE patient, whose case I shall presently give you in brief outline, provides us with a motive for considering the steps by which a diagnosis of malignant disease of the stomach may be reached. From this consideration is excluded malignant disease beginning at the pylorus, with resultant early obstruction and retention of stomach contents. The case which is taken as the text is one in which the body of the viscus is affected, and in which neither the inlet nor the outlet is encroached upon. The case presents a sequence of phenomena, as these are presented in the patient's history, of malignancy at the fundus following close upon hyperchlorhydria and the healing of a pyloric ulcer.

CASE 1.—John R., æt. 47, coal miner, recommended by Dr. Miller, Tranent, was admitted on January 5th, 1916.

Complaint.—He complained of a dull pain about the level of the umbilicus, which sometimes went through to the back and extended across the abdomen. The pain caused nausea, but he had not vomited.

History of Stomach Symptoms.—In November, 1914, he began to suffer from a dull pain in the epigastrium, and extending to the right and the left. He would have the pain for a few days, and then he would be a few days without it. With the pain there might be a feeling of sickness. The pain was worse when the stomach was empty, and it was relieved by taking food. In February, 1915, the exact day being unimportant, he suddenly one day felt faint, and fell down apparently in a faint. He was put to bed, and when he recovered from the faint he vomited dark-brown material. In a day or two he passed black-coloured motions. The doctor told him he had a gastric ulcer. He was kept in bed for three months, during which time the abdominal pain gradually lessened and finally disappeared. After the lapse of five months he felt well enough to return to work. Having worked for six weeks he began to have pain, which he referred to the heart, but which we may assume meant the fundus of the stomach, palpitation and breathlessness. He stopped work, and was off work for six weeks, part of the time being in bed. On September 6th, 1915, he was sent to see me at the Infirmary. He then had pain in the epigastrium extending laterally. He had sometimes nausea and fluid eructations. The pain was relieved by taking food. The bowels were regular. Nothing abnormal was made out on examination of the abdomen, and there was no gastric dilatation. I advised that he should be treated as a case of hyperacidity. The treatment gave so much relief that he was able to return to work, and he worked for several weeks. But he had to give up work again on account of the pain, which he again referred to his "heart," palpitation and breathlessness. The doctor's medicine again relieved him. About the middle of December he began to locate his pain in the umbilical region. The pain was persistent and constant up to the time of admission, and continued constant during the week he was in the ward. He had lost 19 lb. in weight since June last.

Examination on Admission.—He was spare, but not emaciated. His colouring suggested not only some anæmia, but cachexia. The abdomen was the only part of the body that required special consideration, as the other systems were normal.

Examination of Abdomen.—Again I seek to impress upon you the importance of learning to examine the abdomen methodically and correctly. In this patient, inspection to the educated eye showed a slight prominence in the left epigastrium extending to the costal margin. The prominence did not protrude more than half an inch, and it was about three inches or less across. Peristaltic movements were not seen anywhere. On palpation there was a distinct sense of resistance over the elevated area, and the sense of resistance extended over the adjoining ribs. A lower limit to the area was palpable. On percussion the normal area of fundus tympanicity was wanting; heart dullness was continuous, with the dull note over the area indicated.

Let us look at the significance of these observations. A slight projection leads you to palpate the projecting area, and there is found to be a sense of resistance: in palpation of the abdomen there is a wall resistance and an internal or deep resistance. The resistance in this case was not the resistance of a segment of contracted rectus muscle; it was deeper, its lower limit was definite, and the sense of resistance extended over the adjoining ribs and spaces. The sense of resistance in this area was quite different from that of the corresponding area on the right side. This area was also dull on percussion, and the dullness was continuous, with the dull note over the area where fundus tympanicity is normally present. The absence of this area of tympanicity is often an important point in the investigation of stomach conditions, and its absence or presence is to be noted as well as any extension of the area. In a case of the kind we are considering the two available explanations of the dullness were that it was due to an enlarged left lobe of the liver or to the thickened anterior wall of the stomach. The latter explanation easily obtained priority by the obtaining of a squeaking or gurgling sound when palpating the swelling—such a sound as is obtained by squelching the stomach when it contains a little air and a little semi-fluid food. We were fortunate in examining at a time when this phenomenon was obtainable. Once it is felt there need be no doubt as to the seat of its production; it cannot be produced in the liver, its position is too high for the transverse colon, and manipulation of the colon only gives it when the colon contents are semi-fluid, as after a dose of saline. The physical examination of the particular region thus provided evidence pointing to the anterior wall of the stomach as being thickened and infiltrated, and perhaps even adherent to the parietal wall. Palpation further revealed enlargement of the glands above the left clavicle. A test meal showed entire absence of free hydrochloric acid in the stomach. The general observations made regarding the patient's condition were that he had lost considerably in weight within

recent months, that there was a progressive sense of loss of strength, that there was not only a certain measure of anæmia present, but there was a face colouring which suggests not anæmia only, but anæmia plus cachexia.

Diagnosis and Remarks.—From these data we conclude that this patient has malignant disease of the fundus of the stomach, that the enlargement of the supra-clavicular glands points to a wide involvement of internal glands, and that therefore surgical measures need not be considered. I particularly want you to note that the methods which provide the data on which the diagnosis is based in this case are not difficult to acquire some skill in. You must not, however, think that you have only to place your hand on the abdomen to discover all that can be made out. It requires careful and critical training on your part to attain to that; I can only show you how I do it, and tell you what I feel, and it is my duty to give some of you the opportunity of doing these things under my own eye. The skill is attainable by every one of you.

Although this is strictly true, there are factors of experience and of judgment which enter very specially into the problems of abdominal diagnosis. In the case we have been considering there was first a diagnosis of gastric disorder, then of hyperchlorhydria, of ulcer, of healed ulcer. Then comes a change in the symptoms: there was a general deterioration, manifested by evidences of debility, not present in mere functional disturbances of gastric function. Then there was the result of physical examination, the recognition of a swelling which we decided was in the stomach wall, and that such a swelling was almost certainly malignant, and that that view was strengthened by the presence of enlarged glands and no free HCl in the stomach. I have thus shown you the steps by which a decision was arrived at—by a combination of observations, no one of which is in itself pathognomonic of malignant disease, and yet which can be so fitted together that the trained judgment hardly hesitates as to the verdict. Even if part of our mental visualising were proved to be inaccurate, the main conclusion, that the case was one of inoperable cancer of the fundus end of the stomach, would, we believe, be confirmed.

In further illustration of the subject I have been expounding to you, I ask your attention to the facts of another case just admitted to my female ward.

CASE 2.—Mrs. C., æt. 63, admitted on January 15th, 1916, was sent to me by Dr. Melville, Penicuik. She had been under treatment for stomach symptoms for some months without material improvement in her condition.

History.—During last summer she had suffered very greatly from flatulence, a new experience to her, for she had never been ill. In August, after a day in Edinburgh, she was very "done up." From the beginning of September she rested and lived on milk, but without improvement. It required very direct questioning to bring out the significance of those early months. She denied having suffered any pain or that fluid material was ever eructated. When asked about her appetite, she granted that it was not good at that time, that she had no desire for food, and that therein lay a difference from her ordinary condition. When asked if she felt she was weaker at that time, she granted that she was "not going out so much," as she felt tired after it. She then volunteered the information that she did not always get up to breakfast. In fact, there was a clear history to be wormed out of our patient of a definite and progressive debility, which in her mind was so associated with flatulence, that flatulence became the malady, and progressive debility merely a side manifestation of it, and

inevitable. This was the part of the picture, or of the history which required some skill to fill in, and you note the importance of it, for it gives you a picture of the early weeks and months of a stomach cancer in a patient of 63 years of age. This phase continued until November, when vomiting was added to the symptom of flatulence. For a fortnight she vomited every second day, then the vomiting fell to every third or fourth day, and at one time there was no vomiting for three weeks. Then there were daily attacks for a fortnight, followed by ten days of freedom. On January 11th vomiting more severe than ever came on, and she was admitted to the Royal Infirmary on the 15th. The description of the vomited matter was that it varied in quantity from two to four breakfast cupfuls. It was either greyish or brown in colour, of a bitter taste, and sometimes as thick as gruel. There was no feeling of nausea and no pain before vomiting. The vomiting removed a feeling of distension of the stomach which preceded it. The bowels moved fairly regularly, but the dejecta varied in colour and in consistence.

Family History.—The patient's mother died of "blockage of gullet"; a sister died of cancer at the age of 50.

Condition on Admission.—The patient was still plump, although she had lost much in weight. The expression was that of a calm, self-possessed, steady character. The face colouring resembled that of the first case I described to you; it suggested cachexia rather than pure anæmia.

Abdomen.—The abdomen was large, and showed considerable fat in its wall. There was a fullness in the right iliac region, not present in the corresponding area on the left side. On palpation in this region, there was a definite elastic swelling, which felt so like a cyst that it suggested either a right ovarian cyst or a displaced and cystic kidney; it was not tender. On examination of the epigastrium, there was palpable what at first was thought to be the liver, but on more careful palpation was clearly not liver. It was a pear-shaped swelling, the thick end of which was to the left; it lay transversely in the epigastrium from the edge of the ribs on the left side. It was not painful on pressure. On percussion the area of normal fundus tympanicity was not only present, but was considerably extended upwards and to the left. During the few days the patient was in hospital there was frequent vomiting, consisting of thickish, grey-coloured material consisting of little pieces of curd of milk, of gruel, or of the starch of bread she ate. At other times it was more fluid and brown in colour. The vomiting was not preceded by pain or nausea, and the vomit was brought up without discomfort. No specimen of the vomited matter contained free HCl. The bowels were easily acted upon by means of water allowed to pass slowly into the bowel from a douche-can. There were no enlarged glands above the clavicle.

Diagnosis.—The diagnosis was malignant disease of the pyloric third of the stomach. The cystic-like swelling in the right iliac region did not, in view of this diagnosis and in the absence of symptoms which could be attributed to it, require further measures of examination, such as cystoscopy or the collection of urine from the individual kidneys. Both Dr. Haig Ferguson and Mr. Dowden kindly saw this patient with me.

Remarks.—The early history of this case as it has been presented to you is not unique: it is a picture of what usually happens in malignant disease of the body of the stomach. Pain is often absent if considerable ulceration or if irritation leading to adhesions to contiguous parts have not occurred. The failure of appetite, the loss of the desire for food,

the slowly progressing debility without any blood lesion beyond secondary anæmia, the loss of weight, the prominence of a gastric symptom, such as flatulence was in this case; and the failure of medical measures to improve the appetite, to stop the flatulence, to arrest the progressive weakness, all suggest to the experienced physician that malignancy is in the background, although there is nothing abnormal to be made out on palpation of the abdomen. A test meal and the examination for free HCl is valuable at this stage, for, if free HCl be absent, it so strongly supports the diagnosis of malignancy that the question of opening the abdomen becomes urgent, in the hope that the condition is so early and is sufficiently localised to allow of its removal by the surgeon. In a case like this there are thus two practical questions set to the clinician: (1) Is it malignant? (2) Is the surgeon likely to be able to remove it? The second question hangs upon the first, and this is why it is so important to make an early diagnosis. The picture I have given you of the first few months of indisposition in a hitherto healthy woman, with no discoverable lesion in any other organ, and who does not respond to intelligent treatment may lead you, ought to lead you, to this point: that your patient is so probably suffering from malignant disease that you have to *prove* the negative; and if that cannot be done, you must remember that a cancer of the body of the stomach can only be removed if taken early. This early period in our patient lasted for fully three months. It was not until November that vomiting became a symptom; once it started it continued, although at varying intervals—every day or two, or even extending to three weeks. The vomiting latterly became more frequent and persistent, while during the days she was in the Infirmary she vomited oftener than once each day. There was no pain before the vomiting, nor nausea, only a certain sense of fulness was relieved by it. It seemed as if whatever nourishment she took accumulated in the somewhat large fundus, and after lying there for a time was simply ejected, while little of it passed along the pyloric end to the duodenum. The state of nutrition warranted the assurance that some nutriment passed. From the history I think it may be assumed that the malignancy did not begin right at the pylorus; had it done so there would earlier have been evidences of pyloric obstruction. As soon as malignancy occurs at the pylorus it gives rise to pyloric spasm, with retention of gastric contents, early gastric dilatation, and vomiting of retained contents. In the present case vomiting was a delayed symptom, and when it did appear it was so regularly and easily accomplished that no great dilatation of the fundus had developed. By the time she was admitted to the ward, the whole pyloric antrum, judging by its uniformly thickened condition, was involved.

As to medical treatment, it is unfortunately confined to amelioration of symptoms, and to giving as much concentrated and predigested or readily digested food as possible. Our first duty as physicians and practitioners is early diagnosis, and I do not hide from you the difficulty of early recognition. The rule to guide you may be laid down as follows:—When patients who suffer from gastric disturbance, and who have been treated along sound lines without benefit, and especially if they lose weight and complain of unwanted muscular debility, it is your duty to no longer assume that the case is only one of ordinary indigestion or dyspepsia, but to have it thoroughly investigated with a view to determine whether or no it is malignant. The methods of examination are palpation, percussion, test meals, and X-ray examination, and the exclusion of disease in other

organs which might simulate malignant disease of the body of the stomach. In some cases malignant disease may be so situated in the body of the stomach that palpation and percussion give no data and where the diagnosis is determined by the history and the phenomena grouped round it, and the absence of free HCl.

ORIGINAL PAPERS.

A CONVENIENT RADIUM EMANATION TABLE FOR CLINICAL WORK.*

By WALTER C. STEVENS, M.D., B.Ch.,
D.P.H.,

Surgeon and X-Ray Officer, Dr. Stevens' Hospital; Surgeon, Orthopædic Hospital, Dublin; Captain, R.A.M.C. (Temporary).

ON November 5th last I had the honour of reading before this section a paper (a) on a method of recording radium dosage illustrated by a series of eleven cases treated by one set of radium emanation capillaries in needles. The emanation was used for ten days, till the quantity present was reduced from 37.8 millicuries to 6.2 millicuries. There were fourteen doses administered, and in each dose the average amount of emanation used with the patient had to be calculated by a series of multiplications, the multiplying factor being obtained from a table showing the decline of activity of 100 millicuries at certain intervals of time. Most tables available up to the present seem to be published rather for their academic interest than their practical value. Using even an extended table, such as I showed you, to ascertain the activity of 37.8 millicuries in two days two hours, it is necessary to multiply together 37.8, .697, .9925 and .9925. "Multiplication is vexation," and an approximation is most likely substituted, which in turn is often used as a basis of another approximation. Even if the figures are actually calculated mistakes are liable to occur, as I know to my cost, which will vitiate all the later figures. I have found that all this drudgery is avoided by the use of the table before you, which shows one at a glance not only that the activity of 37.8 millicuries in two days two hours is 25.9 millicuries, but also its activity at any intermediate or subsequent hour.

Some points in the table require consideration. From it, which may not be at first obvious, the hourly decrease of any quantity of radium emanation—that is, after it has reached its maximum four hours after collection—can be read off for an indefinite period.

The table may be conveniently considered under headings I., II., etc.

I. Primarily the table shows the hourly decline in activity of 1,000 millicuries of radium emanation until in twelve days nineteen hours there remains 100 millicuries, or 10 per cent., of the original amount present. The last column in the table has five blank spaces. These spaces may be filled legitimately by the five numbers in the one to five hour lines in the first column by the insertion of a decimal point with one place of decimals. The activity of 1,000 millicuries in twelve days twenty-four hours, or at the end of the thirteenth day, or the beginning of the fourteenth day is 96.3 millicuries. The successive columns in the fifth hour line, with one place of decimals, show the activity at the end of the thirteenth to the end of the twenty-fifth day. Similarly the quantities remain-

NOTE.—The first column of the table is a copy of Rutherford's figures published in 1912. The successive numbers can be obtained by multiplying by .99253, which factor therefore represents the relative amount of emanation remaining at the end as compared with the quantity at the beginning of each hour.

The numbers in the first and last lines—the same numbers as these represent the amounts remaining at the end of each day or the beginning of the next—are taken from Colwell and Russ (1915).

The remaining numbers are calculated or averaged.

ing at the terminations of the twenty-sixth to the thirty-eighth days are found in the successive columns of the ten hour line with two decimal places, and of the thirty-ninth to the fifty-first days in the fifteenth hour line, with three decimal places, and so on. In fact, provided the 10 per cent. reduction takes place in exactly twelve days nineteen hours the table shows correctly that in a year 292×10^{-27} millicuries remain.

II.—The table deals with 307 hours and contains 301 different numbers. It is obvious that the hourly decrease of activity of the amount of emanation corresponding to any of these numbers—and also these numbers multiplied or divided by 10 and its powers by the addition of noughts or decimal points—may be read off directly from the table. It is immaterial therefore whether the maximum amount of emanation is 1,000, .267, 2,610 or 116 millicuries, as all these numbers are represented on the table. Thus, .672 millicuries at the end of an hour will be .667, and at the beginning of the ninth hour will be .633 millicuries, while in 24 and 48 hours respectively there will be .561 and .468 millicuries—that is, the figures on the same line but in succeeding columns.

Again, the hourly decrease of a maximum of 116 millicuries may be traced directly for 20 hours till it reaches 100 millicuries, and the quantity present at the end of the 21st hour is shown by dividing by 10 the number in the first hour line in the O day or the first day column, and is 99.3 millicuries. The

When the table was finished it was found that the numbers for the 14th, 16th, 18th, 20th, 24th, and 30th days also agreed with those of Colwell and Russ.

In each number the first two figures are on the whole accurate, the third is an approximation to the nearest whole number. The units figure is the cause of some apparent discrepancies, and reduplication of some numbers on the table. Thus the two consecutive 129 shown might represent 129.49 and 128.51, each an error of less than half per cent.

When using the table, the first or 0 hours line is always disregarded, as it is the same as the last or 24 hour line.

amount at the end of the first and each succeeding day to the thirteenth is shown in the 4-hour line.

III.—When a supply of emanation at the time of its maximum does not correspond to a number on the table, it is obvious that in less than an hour later the amount remaining will correspond to the next lower number. If it is assumed—which, for practical purposes it may be—that during one hour emanation decreases at a uniform rate, and not exponentially, it is easy to calculate when the next number will be reached. If this time and number are substituted for the time of maximum and the amount supplied, the table may be used as before. Thus, a supply of emanation is received which reaches its maximum of 64.4 millicuries at 4.21 p.m. A reference to the table shows the numbers 647 and 642. Their difference, 5, is the amount lost in an hour, or a unit is lost every 12 minutes. At 4.45 p.m., therefore, the activity of 64.4 millicuries will be 64.2, a number on the table from which its hourly decrease, reckoned from 4.45 p.m., may be traced. In effect, in order to co-ordinate a supply of emanation with the numbers on the table, it is sometimes necessary to compensate a slight loss of activity by a small gain in time.

IV.—In using the table, it is immaterial whether the activity of the emanation is estimated in millicuries—i.e., in equilibrium with Ra, radium element, or as being in equilibrium with a radium salt. As the relative activity of emanation measured by the various standards is constant, so

the hourly decrease in activity will conform with the numbers on the table.

As has been pointed out on a previous occasion (1), in recording dosage it is a decided advantage to adhere to the millicurie and radium element standard as the most uniform, logical and generally convenient standard of measurement. Emanation in equilibrium with the radium salts below may be reduced to millicuries, or *vice versa*, by employing the following formula:—

MILLCURIES.					
Ra	RaSO ₄	RaCl ₂	RaCl ₂ .2H ₂ O	RaBr ₂	RaBr ₂ .2H ₂ O
1	1.424	1.315	1.474	1.723	1.81

V.—Since the rise of activity of de-emanated radium is the complement of the loss of activity of the equilibrium amount of emanation for the same period, the amount of emanation formed from a given amount of radium in any given time may be found from the table by a simple subtraction. A radium salt in a sealed receptacle remains in emanation equilibrium because the same amount of emanation is formed as is lost in a given time. A radium salt showing an activity of 1,000 millicuries will for practical purposes show the same activity in an hour, a day, a week, or a year later, as the period of radium is 1,690 years. The emanation table, however, shows that 1,000 millicuries of emanation will lose in an hour 1,000—993=7 millicuries, in a day 1,000—835=165 millicuries, in a week 1,000—283=717 millicuries; or, to put it in another way, 1,000 milligrammes of radium metal will have to produce 7 millicuries per hour, 165 millicuries per day, and 717 millicuries per week in order to maintain emanation equilibrium and register on the electroscopes 1,000 millicuries. Therefore, to find the amount of emanation, a given quantity of radium element or salt will collect in a given time, it is only necessary to subtract the amount of emanation left in that time as shown in the table, from the amount of emanation in equilibrium with the radium or salt, also shown in the table. As about 10 per cent. of the quantity of emanation present is lost during the collection from a radium solution, when the amount of radium does not correspond to a number on the table the next lower number is accurate enough for practical purposes. However, the theoretical quantity can be ascertained—as for example, 92.6 milligrammes of radium in four days, two hours, will collect 92.6+.6—44.2—.288=48.112 millicuries of emanation

VI.—It is obvious that if a supply of emanation is not measured by the electroscopes till some time after it reaches its maximum, the activity at its maximum can be easily ascertained from the table. Thus, if a supply of emanation shows an activity of 144 millicuries twenty hours after it is sealed off, it would have reached its maximum sixteen hours before measurement, and the table shows that its activity at that time was 164 millicuries.

VII.—For clinical work the table has great advantages. With it before him the operator is in a position on the spot to estimate, or subsequently to record, the average quantity of emanation employed, and has not to await a suitable opportunity to calculate it out. He can ascertain at once the amount of ionisation effected by a certain length of exposure, or the length of exposure required to affect a certain intensity of ionisation, taking into account, of course, by how much ionisation is reduced by the screen used. Briefly, it is much easier to find the activity of emanation by counting lines, *i.e.* hours, or columns, *i.e.* days, than by multiplying together a series of numbers. I have previously pointed out that the average amount of emanation

employed during an exposure is approximately the amount of emanation present at half-time in the exposure. For instance, 81.7 millicuries of emanation are buried in a tumour at nine a.m. on January 1st for sixteen hours, until, as shown in the table, the activity is reduced to 72.4 millicuries. If these two and the intermediate fifteen numbers are added together and divided by seventeen, or the sum of the intermediate numbers divided by fifteen, the result 76.9 millicuries is the average activity of the emanation employed, and is the figure on the table showing the amount of emanation present at the end of the eighth hour after treatment is begun or at half-time in the treatment. Therefore to find the average amount of emanation employed it is only necessary to count down half the number of hours in the exposure. If the exposure is for seventeen hours the quantity factor is the mean of the numbers at the eighth and ninth hours, in this case 76.6 millicuries. As before these two exposures may be conveniently recorded as 76.9×16=1,230.4 millicuries-hours and 76.6×17=1,302.2 mch., where the quantity factor and the time factor of a dose are put down in the order indicated by the term millicurie-hour, and their product in millicurie-hours indicates the total amount of ionisation effected, having due regard for the effect of the screen used. If the same supply of emanation is buried at eleven a.m. on January 2nd, *i.e.*, one day two hours after its activity was 81.7 millicuries, the table shows its activity to be 67.2 millicuries; if this is left in for eight hours the average dose is found four numbers down and is 65.2 millicuries.

One error that is liable to occur in using the table is from miscounting the days and hours, which it is comparatively easy to do if pressed for time. To avoid this possible source of confusion I have modified the table as below, with an example of the particulars of a supply of emanation to illustrate the use of the table.

In the revised table the numbers of days and hours are left blank, so that the dates and times corresponding to the supply of emanation may be filled in opposite their proper lines and columns. The numbers in the 0 hour line, except 1,000, are omitted, as they are the same as those in the twenty-four hour line and are liable to be counted in mistake. The lantern slide also illustrates a form of leaflet, which might with advantage be sent out with each supply of emanation from a radium institute. If the time of maximum activity, and its measurement is recorded on the leaflet, the surgeon has all the particulars he requires for estimating his dose with the least labour to himself. It is convenient to have the table showing the rise of activity of radium emanation till the maximum is reached in four hours, as it is sometimes possible to obtain the supply before it reaches its maximum. By using it for about two hours before maximum, the average activity is as great, or greater, than for two hours after that time.

In conclusion, I wish to express my indebtedness to Mr. Moss, scientific director of the Royal Dublin Society Radium Institute, for furnishing me with the printed copies of my table, which you have before you.

Eight Capillary Tubes of Radium Emanation.
Maximum Activity 65.15 millicuries.

At 4.59 p.m., January 4 ^h , 1916.

	842	702	587	490	409	342	
	835	697	588	486	406	339	7.53 a.m.

Note.—The line under 647 denotes that the record of the supply of radium emanation starts at that number, remembering that 64.7 is the actual activity in this case.

The hour 5.53 p.m. in the right-hand time column is the time calculated from the data supplied, at which the activity is 64.7 millicuries.

The line from under 619 to the right divides the days, the date above the line being one day behind that below the line.

When the activity of the supply goes below 10 millicuries, the dates, and the times in the right hand column are cancelled, and the dates—in brackets here for clearness—and the hours

in the left-hand column, also in brackets, are substituted. The later particulars should only be filled in when they become necessary.

If the dates and hours are filled in on the table as above, to ascertain the average amount of emanation employed in an exposure it is only necessary to read the figure on the table opposite the hour and date at which half the exposure is over. Thus if the patient is treated about 9 a.m. on January 7th for six hours, the average quantity of emanation used on him will be opposite 11.53 a.m. on that date, and is seen to be 39.4 millicuries.

THE TREATMENT OF WOUNDS OF THE KNEE-JOINT.

By SURGEON-MAJOR VICTOR PAUCHET.

(Of the French Military Health Service).

[SPECIALLY REPORTED FOR THIS JOURNAL.]

WOUNDS of the knee joint constitute some of the most serious and most difficult to treat of injuries received in warfare. The number of amputations and deaths resulting therefrom is formidable. Prompt, energetic surgical treatment alone will save life and limb.

Now this is what usually takes place. A soldier with a wound of the knee is admitted to a hospital somewhere in the rear. To begin with, the joint is put up in a gutter splint for a day or two and the patient is kept under observation or is transferred elsewhere. His temperature begins to rise. The surgeon performs a timid arthrotomy, that is to say, he makes an incision on each side of the patella, in spite of which the septic condition tends

to get worse. The operator then makes a sub-tricipital counter-opening or one or more openings posteriorly, but still the infection progresses. The surgeon then resects the knee, whereupon the patient's state becomes frankly unsatisfactory, his temperature runs high and cachexia sets in. As a last resort the surgeon amputates through the thigh and the patient succumbs. This, then, is the history of a wound of the knee joint in quite a large proportion of the cases.

Now why, let me ask, are wounds of the knee joint so serious? No doubt because they are usually associated with bone lesions, splintering of the femoral or tibial epiphyses, separation of the condyles, etc. When the injury is caused by a rifle or shrapnel ball only the soft parts may be damaged, and it is within the limits of possibility for the wound to heal without any troublesome complication. As a rule, however, the injury is inflicted by fragments of shell which carry in with them bits of cloth, thus practically ensuring the development of sepsis. The seriousness of the case is aggravated by a lack of decision on the part of

the surgeon, so that each intervention comes too late.

Arthrotomy is performed after sepsis has set in, resection is done when it becomes plain that arthrotomy is insufficient, and, lastly, amputation is resorted to as a last resource after much hesitation. Now each of these decisions ought to have been taken at an earlier and more opportune date, and were this the case many lives and limbs would be saved.

Our rules of conduct comprise:

(1) *Immobilisation and Evacuation.*—Hospitals at the front ought to be specially reserved for laparotomies, arrest of hæmorrhage and real immobilisation of osseous and articular lesions. The wounded should then be dispatched by motor car at least 20 or 30 miles to the rear, to hospitals where they would remain until convalescent, especially if they have sustained wounds of a limb. The mere fact of passing from the hands of one surgeon to another aggravates the prognosis *per se*.

To immobilise the knee we must have recourse to a coxalgia plaster splint extending from the hip right down to the toes (Salot). This fixation is often the means of preventing septic infection taking place or getting worse.

The so-called gutter splints and other metallic appliances are mere snares and never immobilise anything. To really prevent movement of fractured limbs we must either correctly apply a Delbet apparatus or make an enormous plaster splint in accordance with the models given by Calot (*vide the Journal des Praticiens*).

(2) *Radiography of the Knee.*—It is indispensable that we should know for certain whether there are lesions of bone or foreign bodies within the joint. An excellent radiographic service has been in working order almost from the onset of war, so that surgeons have had nothing to complain of from this point of view.

(3) *Armed Expectation.*—If we are dealing merely with a lesion of the soft parts, if the wound appears to be slight, we may adopt an expectant attitude with simple immobilisation, but only on condition that we keep a sharp look-out on the temperature chart, prepared to intervene at once should there be the slightest menace of local infection.

(4) *Arthrotomy.*—In the absence of lesions of bone, should there be effusion into the joint and when there is mild sepsis, we may limit our intervention to arthrotomy with triangular drainage tubes; to lateral and vertical incisions on each side of the patella, and a third, sub-tricipital. The transverse drain unites the two lateral incisions, and the oblique drains place the two lateral incisions in communication with the supra-patellar incision.

Should there be lesions of bone, arthrotomy thus performed may prove insufficient, so that it is not worth while wasting time trying it. We must at once perform transverse arthrotomy, by means of a horse-shoe incision as for resection. Divide the patellar ligament and the two lateral ligaments, and the gaping wound enables us to remove splinters of bone, etc. Moist dressings with Dakin's solution, and if necessary, continuous irrigation.

(5) *Resection.*—This will only be decided upon after making the transverse incision, either because the lesions appear to render repair quasi-impossible or because infection of bone seems unavoidable, or because there is already septic mischief present with grave suppuration, whereupon we must resect forth-without hesitation. A third of an inch of the tibia is removed, an inch and a half or so of the condyles, and the parts are fixed in apposition with bronze wire. Two, three or four drains are introduced on either side. One stitch is placed in the skin. We must not wait for infection to take place before performing resection. It is perfectly useless

to resect when the wound is already infected. We must, if possible, resect before the wound has become septic, otherwise it means amputation or death.

(6) *Amputation.*—If the lesions are serious, if the lower third or quarter of the femur is involved, if infection takes place in spite of resection or arthrotomy, we must amputate, and this without any delay, otherwise amputation spells death.

If we try to be too conservative of a limb we fail to save either life or limb.

In short, the most conservative surgeon is he who, from the onset, arrives at a decision in regard to the lesion and acts upon it forthwith.

The subsequent measures are of capital importance, and this is one reason why the patient should not change hands.

THE THAMES VALLEY: CERTAIN OF ITS NATURAL AND MEDICAL ATTRIBUTES.*

By S. D. CLIPPINGDALE, M.D.

Vice-President of the Balneological and Climatic Section,
Royal Society of Medicine.

THE author, after briefly acknowledging the valuable help received from Medical Officers of Health in the confirmation of his paper, among whom he mentioned Dr. Alfred Greenwood, Dr. Harry Jones, Dr. Frank Laurance, Dr. J. M. Martin, Dr. James J. Paterson, Dr. C. Grant Pugh, Dr. Wm. Sisam, Dr. John C. Thresh, Dr. John T. Thomas and Dr. Herbert Williams; he proceeded to remark that the River Thames is, and some of its tributaries are possessed of certain attributes which seem to have a definite bearing upon the health of the riparian dwellers. The subject, I think, has not been dealt with before in a concrete form and seems a fitting one to bring before this Section of the Royal Society of Medicine. I regret, however, that from want of a deeper knowledge of the subject I can only do so in a very imperfect manner.

Definition.—But first it is necessary to define the River Thames, for, strange as it may seem, the identity of our metropolitan stream is by no means beyond dispute. Until recently, that part of the river which proceeds westwards from its junction with the Thames at Dorchester, was known as the Isis. It was so called by John Leland, in the time of Henry VIII., by Edmund Spenser in the time of Queen Elizabeth and by Isaac Walton, in the time of the Commonwealth. The Isis, after its junction with the Thames, was called by the Romans "Thamesis," and upon an old map, of which I have a copy, it is spelt as a hyphenated word. The Isis is so named upon all maps published down to thirty years ago and later, and is still so called by the people of Oxford and Oxfordshire.

Of late, however, an edict has come forth from those who are supposed to know, and founded upon some words in a Saxon charter, that the name Thames applies to the entire length of the river and that the river Thame is a tributary. We have thus the curious condition that a river of one name has a tributary of a very similar name. (a)

To account for the name Isis, it is suggested that this was created by the Dons of Oxford,

* Abstract of paper read in the Balneological Section of the Royal Society of Medicine.

(a) If it is suggested that the river Thames takes its name from the town of the same name, and that there is no corresponding origin for the name Isis, I would venture to suggest that the village of Eisey or Isey, on its banks near Lechlade, may possibly supply such an origin.

though why the Dons of Oxford should have named their river after a heathen goddess, who is not known to have had any territorial connection with the place, is not explained.

Source.—Accepting, as in duty bound, what is now regarded as authority in this matter, we have next to determine the head of the river, for like the Hydra, the river serpent with fifty heads, the Thames has many, or rather a great many springs claim that honour. Those who attended, in 1901, the meeting of the British Medical Association at Cheltenham, will remember being taken to a place in the parish of Charlton Kings called the "Seven Springs," over which is the inscription: "*Hic Tuus O Tamesine Pater Septemgeminus Fons.*"

As this source, the seven springs, makes the river thirty miles longer than any other source, I propose to adopt it as its head, although I am not strictly orthodox in doing so.

Length and Fall.—From the seven springs to the North Sea, the Thames runs a course of about 250 miles. The head of the river is 600 feet above its mouth, so that its fall is about 1 in 2,000, *i.e.*, 21 inches to a mile.

The *Width* of the river, of course, increases as it approaches its mouth. At Oxford its width is about 100 yards, at London Bridge 260 yards, at Gravesend 800 yards, and at the Nore 5 miles.

The *Area* of the Thames basin is 6,160 square miles, equal to about one-seventh of the whole of England.

The *Amount of Water* in the river may be imagined, when it is remembered that 100,000,000 gallons pass Lechlade and 380,000,000 gallons pass Teddington in one day.

As to the *Age* of the river, Professor Huxley (12) estimates that the chalk basin alone has taken 7,200 years to form and that the entire history of the river is a matter of hundreds of thousands of years. "There is clear evidence," he says, "that the Thames Valley was the haunt of Savages armed with flint weapons and that Elephants, Rhinoceroses, Bears and Hyenas roamed through its forests.

Geology.—The structure of the Thames basin is interesting geologically, and important medically. Details of its geology will be found in the works of Huxley (12), Jorda (13), Phillips (16), Prestwich (17), Whitaker (19), and Woodward (20). It must suffice here to give a skeleton of the subject and to indicate its points of medical interest.

Every river must, of course, be helped up by a "basin" of some sort, otherwise its water would percolate and disappear. The Thames is held up by two basins which fit one into the other like two table basins of different sizes. The upper of these basins is of clay, the lower of chalk. Between the two is a deposit of what are called "Lower London Tertiaries." Upon the clay basin is a layer of gravel, and above this a layer of alluvial soil. The lower basin, of chalk, rests upon solid rock.

With regard to these different deposits, the uppermost or *Alluvium* is simply material which has been washed down from the watershed, and naturally varies in different places. In the west it is of a chalky nature: in the east it is a rich loam. The thickness of the alluvial soil is from a few inches to about ten feet.

The *Gravel* which underlies the alluvium is what is known as "Valley Gravel," but is structurally the same as other gravels. Medicinally,

it is of interest, as containing an oxide of iron and a little arsenic. The depth of this gravel varies from about five to about fifty feet. It is into this gravel that the wells were sunk which were so graphically described by our late President, Dr. Septimus Sunderland, in his inaugural address, an address which happily for those who did not hear it, has now been reprinted in book form (18). In some places, the gravel is replaced by *Brick Earth*, a soil, says Huxley, very suitable for the growth of vegetables and, as doctors know, very productive of rheumatism.

Beneath the gravel lies the *Clay*. This contains fossils, and is really a marine mud. The depth of the clay in the London district is about 400 feet. It gets thinner towards the mouth of the river, and is absent between Windsor and Maidenhead. Otherwise it underlies the Thames everywhere, but bears different names. In London we call it "London Clay," in Oxfordshire it is known as "Oxford Clay," while up the little river Thame, it is called "Kimmeridge Clay." To a scientific geologist there is apparently a difference between these different kinds of clay, but to an amateur very little, and from a sanitary point of view, none.

The ridges of the Thames clay basin form what are called the Northern and Southern heights of London, and are sometimes four hundred feet above sea level, so that the highest and consequently the healthiest parts of London are upon clay. The soil lying next or near the water course is always either gravel or alluvium. These matters I indicated in a paper I had the honour of reading before the old Balneological Society (5). The paper excited a good deal of criticism, as it represented facts in opposition to received views. I referred, however, to the Registrar-General's statistics and to the geological map of London, and there I left the matter. The fallacy, for such I regard it, as to the superiority of a gravel soil is no new thing. I recently came across the following couplet in Garth's "Dispensary" (Canto III.) published in 1699:

"The sick in hundreds sooner shall repair

And change the gravel pits for Essex Air."

This couplet is written in satire, and infers that it is better to live in the Gravel Pits region of Notting Hill than in the bracing air of Essex, whereas the experience of one tuberculous patient will teach us the contrary.

The clay is capped in some places by Bagshot Sand left by a primeval flood. There is a small patch of this sand at Hampstead. Formerly this sand was carried down to London and spread upon the floors, but it was found that it was washed into the river, which it tended to silt up, to the extent, it is said, of ten feet in fifty years, and the practice was stopped by Act of Parliament in 1760 ("Notes and Queries," Jan. 15th, 1916.)

Below the clay, as already stated, is a layer of *Lower London Tertiaries*. This is a layer 80 feet thick. Its composition varies. It usually consists of Reading and Woolwich beds, but towards the estuary of the Thames there is also an addition of Thanet sand. It is into the Lower London Tertiaries that an Artesian Well must be sunk to collect the water that has gravitated down from the Chiltern Hills on the north and the North Downs on the south, and lies upon the chalk. An artesian well, therefore, to pass through the clay, must be at least 400 feet deep, and is said to cost £1 a foot to make.

The *Chalk*, the lowest of the Thames basins, is about 800 feet thick in the London area, but less thick elsewhere. It rises to the Chiltern and Cotswold hills in the north and to the Wiltshire and North Downs in the south. Its structure varies. In the Chiltern Hills it is laminated, but in the Cotswolds it resembles masses of fish ree, and so is called "oolite."

The *Width of the Thames Valley* varies considerably from the narrow gorge of Streatley and Goring, which is less than half a mile, to the wide expanse of forty miles between Dorking and Dunstable. The river was formerly much wider than it is now, and extended to the chalky crests of its watersheds. At a period still more remote, the Thames was a tributary of the Rhine.

As the centre of the earth's gravity has shifted, so the Thames has been drawn nearer the North Pole at one time and repelled from it at another. Hence in some of its deposits are found the remains of Arctic animals, and in others the vestiges of tropical plants. The presence of Peat in some places is evidence of submerged forests, Pepys the diarist, states that among the things which did surprise him was that workmen in digging a dock at Blackwall, came upon a tree standing upright with nuts upon it ("Diary," Sept. 22, 1665).

Oscillation of the Thames Valley is still going on. In 1660 the magnet in London pointed due N. and S. Then there was a gradual declination to the west, which reached an extent of 25 degrees in 1818. Since 1818 the needle has been gradually returning to its usual position.

The amount of *Rainfall* varies. As might be expected, it is greatest in the western part, owing to the close proximity of the Hills, and lowest in the eastern part, where the surface is flat. (The amount of rainfall at various places in the Thames Valley was shown in diagrams).

Tides.—Below Teddington, that is for a distance of 77 miles, the water is tidal. The water flows and ebbs twice in the twenty-four hours, about five hours being spent in the flow and about seven in the ebb. Vagaries in the tides, however, are on record. In 1638, for instance, it flowed twice in three hours, three times in four hours on March 22nd, 1682, and again twice in three hours on November 24th, 1777. The tides vary twice monthly, and are known as "Spring" and "Neap" tides: the former, in which the water is highest, occurs at the new or full moon, the latter, in which the water is lowest, occurs during the moon's second and fourth quarters. The Spring tides being due to the attractive forces of the sun and moon acting in a straight line, the Neap tides when these forces act at right angles.

Floods, Frosts and Fogs.—The Thames, like other rivers, has often been guilty of eccentricity in these matters. It has often overflowed its banks, especially during a spring tide with heavy rainfall. The earliest recorded flood was in 1235, when lawyers and litigants had to be taken from Westminster Hall in boats. Other historical floods have occurred in 1736, 1748, 1762 and 1791. Since the formation of embankments, however, the river, although it occasionally rises to a great height, does not overflow its banks so far as London is concerned. In the western part of the river, however, disastrous flooding occurs. In the eastern part of the river the water is kept from the Essex marshes by a sea wall, said, by Sir Walter Besant (2) to have been put up by the Romans;

Frosts were formerly more common than in recent times. In 1063 the Thames was frozen over for fourteen weeks. In 1434 it was frozen from London to Gravesend. In 1684 the ice on the river was eleven inches thick, a fair was held on the river and forty coaches plied daily up and down its course. In the winter of 1716 an ox was roasted on the river. The last severe frost of this kind occurred in 1814. Fogs, although they spring from the surface of the river, are often denser on the hills around; the reason is that on ascending the hills they are kept down by a layer of dense cold air. Fogs, however, are now comparatively rare.

Flora and Fauna.—There is not much to record with regard to the Flora except that at certain parts the temperature of the Thames Valley is so mild that sub-tropical plants can be grown. The river banks produce the usual poisonous plants, Foxglove and others, so carelessly eaten by children and so carefully avoided by cattle. Upon the banks of the Thame, Woad (*Isatis tinctoria*), says Mr. Cornish in his interesting book, (8) flourishes to an extent sufficient to stain a whole British tribe. Water-cress flourishes in the streams which come down from the chalk.

Of the birds, the most interesting scenically are the beautiful swans, black and white, which add so much to the beauty of the river. They are all alien birds, and are carefully protected by the Crown.

Seagulls, as is well known, find their way up the river in times of stress of weather. They fly over the bridges, never through them, and locate themselves upon the fresh-water reservoirs at Barnes.

Edible fish, especially trout, is found in great quantity in the upper part of the river and its tributaries. The shrimp is interesting as indicating by the colour of the shell the condition of the water. At the mouth of the river this is pink, at Gravesend it is brown and sometimes black. Before the pollution of the water, salmon flourished in great abundance near London, and the fishermen were wont to offer it as a tithe upon the high altar at Westminster. Since the repurification of the river many fish have reappeared, and whitebait has had the temerity to appear off Greenwich. (a). Recently a porpoise made its appearance in the river, but, says Mr. Cornish, like a true London porpoise it halted opposite a public house and was arrested.

Scenery.—For an account of the Thames scenery I must refer to the many popular works written upon the subject (see References). I can only point out here, that, for grandeur of scenery the Thames cannot compare with the Rhine or even with the Caledonian Canal. There are no castle-capped crags and no waterfalls. But for the soft sylvan beauty which is peculiarly English and for old towns and old churches, the Thames has a charm which is peculiarly its own.

HEALTH.

It is, I think, generally admitted that those who live in valleys are at some disadvantage with regard to health. The reason of this may be difficult to trace. We are all of us conscious that throughout life we are under the influence of two forces, the "Vis Vitæ," which urges us to energy, and the "Vis Inertiæ," which leads to inaction. We feel the former force more before, and the latter force more after, middle age. The former

(a) Greenwich, formerly noted for its ministerial Whitebait Dinners.

asserts itself when we are upon a bracing hill, the latter when we are in a relaxing valley.

Metabolism of our tissues is greater upon a hill than in a valley, consequently our power of resistance is increased and our opsonic index raised. In this way it may be that dwellers in valleys appear to be more prone to illness than those who live upon hills. The Thames Valley, in common with other river valleys, appears to exemplify this, and in the following brief accounts I will mention certain maladies which appear to be so influenced:—

Adenoid Growths and enlarged tonsils in certain parts of the Valley are above the average rate.

Ague.—In the last paper I had the honour of reading before this Section (4) I stated there was formerly prevalent a malady known as "London Ague," and that Oliver Cromwell, Charles II. William III. and Queen Anne had suffered from it. The disease, however, with the introduction of arterial drainage and the closing in of many small streams which formerly permeated London, had disappeared. More recently ague was common on the Essex marshes, and when, in 1877, I was House Physician at the London Hospital, we admitted several cases of it. Dr. Thresh, the Medical Officer for Essex, however, informs me that through the better drainage of these marshes, the disease has almost disappeared.

Anamia, independent of organic disease, as might be expected, is common in some of the more closed in parts of the Thames Valley.

Cancer.—The incidence of Cancer is a difficult subject. We are all acquainted with the views and statistics of Alderson (1), Clemow (3), Haviland (10) and Hirsch (11). Two medical officers in the western part of the Valley and two in the eastern part, report not only super-normal frequency of the disease, but also a tendency to its increase. Some of my correspondents attribute the high mortality from cancer to the great longevity prevalent in their respective districts; but I must confess I was not aware that cancer was a malady especially frequent in old age. In a paper upon the Chiltern Hills, which I read before this Section some years ago (6) I stated I had found cancer very frequent in the Chiltern Valleys, and that it seemed to be of a tribal or family character. I would venture to suggest that this may be the case in certain parts of the Thames Valley. The question of the so-called "Cancer Houses," often undisinfected, may also be considered.

Enteric Fever.—Dr. Thresh, in his medical report for Essex, states that Typhus Fever used to be most prevalent in South Essex, bordering the Thames, but it was proved to be due to people eating shell fish collected on the foreshore. When this was known, the Typhus rate dropped until it is little, if any, higher than elsewhere in that county. On the other hand, Dr. Pugh, Medical Officer for the independent borough of Southend-on-Sea, complains that he still has this difficulty to contend with, and that people eat largely of the cockles, mussels and other molusca which are found at Leigh and around Canvey Island.

Fibrositis, so well described by our distinguished colleague, Dr. Jones Llewellyn, is prevalent in both the upper and the lower parts of the Thames Valley; in the upper part on account of the frequent inundations, and in the lower part on account of exposure to the keen winds of the North Sea.

Gout, as might be expected, is prevalent in

the Valleys of both the Chiltern and the Cotswold Hills.

Tuberculosis.—Perhaps one of the most instructive papers upon the Etiology of Phthisis, was that contributed to the *British Medical Journal* a few years ago by our President upon the influence of rain-bearing winds in developing Phthisis. Dr. Gordon's paper (9), I think, only referred to Devonshire, but his observations apply equally to the upper part of the Thames Valley, which is traversed by the same rain-bearing winds. Another important communication by our President and dealing with the same subject, was his Inaugural Address in which he showed the influence of damp soil as a factor in the production of this disease.

All my correspondents in the upper part of the Valley report a prevalence of Phthisis apart from the question of infection, showing that the prevalence is due to local and not to personal causes.

Towards the Thames Estuary, however, the disease becomes rarer, due no doubt to the purer air breathed by the inhabitants: air that has been purified by its contact with the ice around the North Pole and charged with the salt it has picked up in passing over thousands of acres of ocean. In this connection it is interesting to note that the Essex marshes, "Saltings," as they are called, produce excellent beef and mutton, and it is said the superior mutton called "pre salé" derives its name in this way (Cornish).

Violent Deaths are above the average in all parts of the Thames Valley, the reason being no doubt, as pointed out by Dr. Middleton Martin (14) the presence of the river as conducive to death by drowning, accidental, homicidal or suicidal.

THE RAPID.

In a district which differs so widely in its climate as does the Thames Valley in its long range of 250 miles, it is obvious that cases which are suitable for one part of it are unsuitable for another. For the anæmic or tuberculous, residence near the mouth of the river is preferable, or failing residence, frequent trips down to the estuary. But for the over-worked student or brain-fagged man of business, a stay at one of the quiet villages up-stream, or frequent trips upon the up-river streams, will be found to provide a very effective scenic and atmospheric bromide.

CLINICAL RECORDS.

A CASE OF HÆMORRHAGE IN THE RETINA AT THE YELLOW SPOT.

By JOHN ALLAN, M.D., D.P.H.

It is surprising how apparently trivial injuries of the eye may result in lesions which, temporarily at any rate, may cause marked loss of vision. The following case is of interest in this respect:—

H. C., a married woman about 30 years of age, came to me complaining of loss of vision in the right eye of two days' duration. The eye appeared quite normal, but she could only distinguish fingers at a distance of 2 feet, and even at that distance objects were to her obscured and cloudy. Vision in the left eye with Snellen's types was 6/6. She at first denied any injury, but on thinking the matter over she remembered that two days before, when shaking a small door-mat, one of the corners of the mat had struck her right eye, but she experienced no actual pain, and the injury was so trivial that it had escaped her memory. There was no history of other injury. After dilating the right pupil with homatropine, the fundus was examined with the ophthalmoscope, and hæmorrhage in the macular region was discovered. The fundus was otherwise normal, and there was no error of refraction. The patient maintained that she had always been healthy, and an examination of her various systems on more than one occasion confirmed her statement. Treatment was merely expectant. Domestic duties prevented the patient resting in bed as advised, although she promised to limit her exertions as much as possible. A weak atropine solution was ordered for instillation into the eye twice daily. When seen three days later the condition was much the same; there had been no further hæmorrhage, but it was difficult to say whether or not there had been any absorption of the blood already effused. However, when the patient was next seen, there was no doubt about the hæmorrhage being less marked, and she was able to see objects across the room, although their outlines were still indistinct. Her progress towards the successful termination was slow but steady. Two weeks after her original visit vision in the right eye was 6/36, and a week later 6/18—in both instances the pupil being partly dilated with atropine. This was now stopped, and a week later vision in the right eye was 6/6. A drop of homatropine was instilled into the eye on this occasion to facilitate ophthalmoscopic examination, which failed to reveal any abnormality of the fundus. An inquiry two months afterwards elicited the information that there had been no further trouble with vision.

Hæmorrhage in the retina at the yellow spot is not very frequent, but it undoubtedly occurs, and in most cases it is pathological in the sense of being due to disease. In the case I have just recorded I think disease may be excluded, and the only possibility is that the condition resulted from the very slight injury already alluded to. I recollect seeing a somewhat similar case when I was resident in a seaport town. A healthy young sailor in the course of his duties received a blow on one of his eyes with a piece of rope. There was slight contusion of the lower eyelid, but no other evidence of injury except hæmorrhage in the

macula. The man refused to lie up, and treatment was similar to that above described, and the result was that normal vision was in time re-established. These two cases would seem to suggest that in cases due to injury in healthy subjects a very hopeful prognosis may be given. In cases of macular hæmorrhage, the result of disease, it might perhaps be advisable to be more guarded, but I think it is generally found that even these cases clear up well with a return to vision as good as that present prior to the occurrence of hæmorrhage. In some cases, however, vision may remain defective even though the ophthalmoscope may fail to demonstrate any abnormality in the macular region. It is not inconceivable that some of those people who in later years fail to respond to glasses (after the error of refraction has been properly estimated and carefully measured) may have at one time suffered from unsuspected or unrecognised hæmorrhage in the macular region—hæmorrhage, moreover, which has left no demonstrable fundal changes. This seems to me a possible and quite feasible explanation of these puzzling cases to which I have just referred, and which are occasionally met with. It would be most interesting to be able to follow up these cases of macular hæmorrhage, and to keep them under observation for the rest of their lives, but for various reasons this would not be an easy matter.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

CONSCIENCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have turned the pages of your last few numbers hoping that someone qualified for the task would have commented on Dr. Claye Shaw's statements under date March 22nd and April 5th. It seems from his article and subsequent letter that modern psychology asserts that conscience must no longer be defined as an innate faculty which distinguishes right from wrong; indeed, such is "a false assumption." This is a large order.

A correspondent taking objection to this view is informed that he is confusing conscience with consciousness.

The "Standard Dictionary," Vol. I., page 399 thus defines Conscience:—

"(1) The power or faculty in man by which he distinguishes between right and wrong in conduct and character, and which imperatively commands and obligates him to do the right and abstain from doing the wrong; the moral nature; moral faculty; moral sense.

"(2) Conviction of right or duty . . . scrupulosity; as, a man of conscience.

"(3) (Archaic) Consciousness."

Under (1) is given as an illustrative passage the sentence from Young's "Christ of History": ". . . conscience is needed for the age, as for the individual—a power that shall reveal it to itself, and arouse and convict it."

And surely this is what the average man would mean by the term conscience. When he swears "on his soul and conscience," or says he can or cannot do or obtain from doing a certain thing "conscientiously," he is speaking in terms of the "Standard Dictionary."

Dr. Shaw's extraordinary contention that the shedding of blood is justified by the most atrocious murder in the world's history I pass, but as he

appeals to Scripture, it is in order to remark that conscience, in the above-quoted sense, is expressed or implied therein from cover to cover—from the hiding of Adam after his sin to the life-aim of Paul, "to have always a conscience void of offence toward God, and toward men." And if the "Light which lighteth every man that cometh into the world" does not operate through what we term conscience, then I know not what those words may mean. Blurred and dimmed grievously this light may be, indeed, but some glimmerings of it are always to be found, save in those whose fearful lot it is to "have their conscience seared with a hot iron."

In none, perhaps, was the Light more dimmed than in those New Hebridean cannibals among whom Dr. Paton laboured. I find in his "Life" that he mentions certain revolting instances of their habits, and adds, "All such cruel and horrible practices, however, they tried to conceal from us." This experience I believe has been that of various other missionaries. But why this sense of shame in such degraded beings as these cannibals? If it came not from conscience, how is it to be accounted for? Not, I imagine, by "the state of consciousness, . . . the result of the physical processes which the various environmental excitants bring about in the brain," this last being, as I understand from Dr. Shaw, modern psychology's evaluation of "conscience."

It was the business of Lord Roberts—and few fulfilled it better than he—to be a reader of men as well as a leader of men. At the risk of multiplying quotations, I will venture to recall his words in this connection:—

"If you penetrate deep into the depths of human nature, you will unfailingly reach in each one of us a stratum which is impervious to discipline, or any other influence, from without. The strangest manifestation of this truth lies in what men call conscience—an innate sense of right and wrong which neither reason nor man-made law can affect."

I have no more sympathy with conscientious objectors than has Dr. Shaw, but his way of grouping them all together as a body of degenerates afflicted with "a selfish consciousness" is unworthy and unjust. There is a residuum of these men for whom, although profoundly disagreeing with their sense of right and wrong, I have a deep respect, as anyone must have who has the least knowledge of the way in which suffering for conscience sake is interwoven with every fibre of the history of the Society of Friends, and not of them only. Such men deserve to be distinguished, and any decent person will distinguish them, from the ruck of cranks and cowards who have been wasting the time of Tribunals. I desire to believe that it is merely an oversight of Dr. Shaw's that he has not so distinguished in his article in your issue of March 22nd.

I am, Sir, yours truly,
L. GWILLIM DAVIES, M.D.

Histon, Cambridge.

PATENT MEDICINES AND THE BUDGET. *To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—In considering the question of the taxation of patent medicines, it is necessary to bear in mind fundamental facts which it seems are liable to be overlooked even in some responsible quarters. The first of these facts is that the traffic in patent medicines is to a large extent fraudulent. At least 75 per cent. of these preparations are not only fraudulent but are put forth with deliberate fraudulent intent. These facts have been fully demonstrated during the past thirty years. Not to speak

of the vast mass of evidence accumulated from many sources, including law reports, the case was proved by the investigations carried out by the British Medical Association, and embodied in the books "Secret Remedies" and "More Secret Remedies," published by the Association. The whole story was unfolded with even meticulous completeness in the Report of the Australian Commission. Lastly, the entire question was exhaustively examined into by the Select Committee on Patent Medicines, whose Report was published in August, 1914. The Report, which was unanimous, ended by naming a long list of classes of patent medicines which the Committee adjudged the most pernicious, and urged that not only the sale but the advertising of these ought to be at once forbidden by law. These condemned concoctions were enough to render the patent medicine trade as a whole an improper source of revenue. It is impossible to believe that Mr. McKenna, when increasing the impost last year, was aware of these facts. Had he been properly acquainted with the question he would have recognised that his action must go far to stultify the tribunal set up by the Government, and to nullify its findings and recommendations. It seems amazing that not one among the permanent officials of the Treasury, the Home Office, or the Department of the Public Prosecutor who were called as witnesses before the Select Committee took the trouble to give Mr. McKenna a hint; he must surely have made some inquiries among the officers of his own Department when contemplating the increase of duty. The second fundamental fact which needs keeping to the front is that the traffic in patent medicines is not only in great part fraudulent, but leads to the infliction of a vast amount of misery and premature death. This remark applies as strongly to those concoctions which contain merely inert or harmless drugs as to those which are made up of ingredients capable of producing serious physiological effects. It is worth while, perhaps, once more exemplifying this fact. Whilst waiting my turn as witness, I heard the testimony of Sir Malcolm Morris and Dr. Whitfield before the Select Committee. They stated that it was quite common to meet with cases of lupus which had passed into an incurable phase whilst the patients had been treating themselves with one or other of the widely advertised "skin cures" of the day. Lupus is curable when recognised and treated in its earliest stages. My own attention was first attracted many years ago to the quack medicine question by a case of cancer of the breast which had passed beyond the reach of surgery whilst the wretched woman had been treating it with the most advertised quack ointment of the day. This was merely coloured grease. Ointments of this kind are now mostly made of a mixture of hard and soft paraffin, coloured and disguised. I am not acquainted with any patent medicine which is advertised merely as a purgative. But there are advertised a great number of medicines (each as a cure for many diseases) which contain merely a small purgative dose. Some time ago I reported in your columns a series of cases of gastric ulcer which I had inquired into at our local hospital. Among six or eight women admitted within about a year with that disease I found that all of them had been dosing themselves with "indigestion cures" which contain merely a small quantity of a cheap purgative. They had all been driven into the wards by the progress of their malady. One died of perforation, and there existed no doubt that her life might have been saved by scientific treatment at an early stage. Cases of this kind due to reliance upon quack medicines are within the common ex-

perience of every practitioner; they are to be found always in every special and general department of all our great hospitals. Shortly before his death, I received from my friend Sir Henry Butlin the report of a long string of cases in his experience in which disastrous results had been brought about in cancer, in tuberculosis, and in syphilis of the larynx through delay whilst the patients were taking patent medicines advertised to cure not only coughs, but all diseases of the throat and lungs. The great majority of these medicines are in themselves quite harmless, being made up of ingredients no more potent than syrup and a little ipecacuanha. Sir Henry Butlin, among half a dozen more of my friends of a similar standing and experience, was prepared to give evidence before the Select Committee if called upon. It is deplorable that writers on this subject, claiming to speak with some authority, do not take the trouble to look through the Report of the Select Committee, with the Minutes in which the evidence of witnesses is given verbatim. They would there find the record of the baneful effects of the quack medicine trade, both as regards concoctions in themselves harmless, such as I have just referred to, and those containing really potent drugs, such as alcohol, morphia and cocaine, all of which act as virulent poisons in the maladies for which they are recommended in mendacious advertisements.

Although I usually take that admirable paper, I did not see the recent article in the *Westminster Gazette*, on this subject. Some weeks ago, in writing in your pages on the attitude of the newspaper Press, I mentioned the *Westminster* as one of the small percentage of papers of similar standing which were taking pains to keep their pages clear of fraudulent advertisements. The conduct of the great bulk of leading newspapers in this regard since the issue of the Report of the Select Committee has been more than scandalous; but, as this letter is perhaps already too long, I propose, with your permission, to deal with this topic in a future communication.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery, Earlswood Common,
April 13th.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your annotation regarding the absence of taxation of patent medicines in the Budget is timely, and the views therein expressed will, I think, voice those of the medical profession as a whole concerning these nostrums. I do not often read Sunday newspapers, as I find quite as much literature of the week left over to be finished that day. Last Sunday, however, I came across a well-known weekly of that date, and in turning over its pages for the latest war news, my eyes were attracted by the huge black type of such announcements as: "Free Advice to all sufferers"; "A Discovery that has Never Failed"; "Anæmia and Nerves soon Made Well"; "Lightning Cough Cure"; "Backache Kidney Pills," 2s. 9d. a box; "Nervous Breakdown Remedies on Government Stamp," etc., etc. With Budget on the brain, I naturally asked myself why the Chancellor of the Exchequer had not seized so legitimate a source of revenue as these quackeries offered by doubling or trebling the patent stamp tax if he could not afford to tax them out of existence altogether. These nostrums are nearly all owned by foreigners who have made and are making huge fortunes out of an ignorant, confiding public; and as the majority now sold at one shilling and two shillings per box, plus the patent stamp, have been conclusively shown by the Select Committee on Patent Medicines to cost their producers

but a fraction of a penny, there should be no hesitation in taxing this ill-gotten wealth to the fullest capacity attainable. Is it yet too late to replace the railway tax now dropped by a heavier impost on patent pills?

I am, Sir, yours truly,

J. WILSON.

April 15th, 1916.

OZONE "Tired Feeling."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Our attention has been drawn to a paragraph headed as above, which appeared in your issue of the 5th inst. in reporting some remarks by Dr. W. Harwood Nutt and by Major Wilson, of the Canadian Medical Service, at a meeting of the Roentgen Society. These gentlemen had quite correctly formed the opinion that ozone was produced in the neighbourhood of the X-ray tube, but their further opinion that headaches, sleepiness and tired feeling experienced by the X-ray workers is due to the presence of ozone is based on wrong conclusions. The condition described is caused by oxides of nitrogen, which are generated with the ozone when the ozone is produced by inefficient or unsuitable methods, as in the case in question. A well-designed ozone generator produces pure ozone, and the effect of this gas, if present in suitable concentration for inhalation, is exactly the opposite to that described, in that it has a stimulating, vitalising property, which conduces to greater activity and better health. This has been proved conclusively by thousands of apparatus and installations supplied by this company. It is true that excessive inhalation of ozone in very strong concentration might produce headache in certain cases, but it would be accompanied by effects the reverse of sleepiness or tired feeling.

We may add that whilst the members of the medical profession in this country do not generally appear to have informed themselves regarding the therapeutic properties of ozone and the excellent uses to which it may be put for the treatment of certain complaints, such as diseases of the respiratory tracts, sterilisation of wounds, etc., nevertheless, there are many individual physicians who have done so and have expressed their appreciation to this company. We are always prepared to give medical men every facility in regard to the study of the subject, and to acquaint them with the opinions of those practitioners who have had experience with ozone treatments.

We are, Sir, yours truly,

OZONAIR, LTD.

96 Victoria Street,
London, S.W.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN
IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, MARCH 10TH, 1916.

PROFESSOR T. H. MILROY in the Chair.

DR. J. R. D. HOLTBY showed specimens illustrating symmetrical division of the medial cuneiform bone of the foot. He quoted from Gruber's and Pflüger's works figures to show that the condition was extremely rare, only occurring in about

0.33 per cent. of cases, and then not necessarily being symmetrical. After referring to the significance of the plantar element as representing a lost tibial ray of the foot, he suggested that the existence of the condition pointed to the possibility of there being, as in some other tarsal bones, always two early centres which, however, usually fused almost immediately. The condition in the living subject, when not symmetrical, might in an X-ray plate be mistaken for fracture.

Professor A. F. DIXON stated that he had made enquiries from X-rayists in Dublin, but could not find that any of them had seen the condition.

Dr. J. M. O'CONNOR described a method of measuring the blood flow through the ear of the rabbit, based on A. V. and A. M. Hills' calorimetric method (*Journal of Physiology*, vol. 46, p. 81). He showed records—from a research in progress—obtained by this method, which made it appear probable that the physical regulation of temperature is controlled by the temperature of the brain.

Professor W. H. THOMPSON read a paper on "Some further experiments on Arginin and Creatin formation in Birds."

Professor T. H. MILROY read a communication on the effect of intravenous injection of various hypochlorite solutions.

HARVEIAN SOCIETY.

MEETING HELD APRIL 13TH, 1906.

The President, DR. EDMUND CAUTLEY, in the Chair.

THE paper of the evening was read by Dr. McCANN on

THE TREATMENT OF BACKWARD DISPLACEMENTS OF THE UTERUS.

It was stated by the author that nearly all such cases of displaced uteri caused certain symptoms sooner or later, and therefore treatment should be undertaken in the early stages. The method of replacing a uterus by means of a sound was condemned as barbarous, and forcible breaking down of adhesions without the aid of sight was stated to be dangerous. The importance of general treatment, such as massage and exercises, was emphasised.

The operative treatment of the condition was critically discussed, and the factors of age, possibility of future child-bearing, and maintenance of normal anatomical relations cited as influencing the choice of operation. Dr. McCann described two operations on the round ligaments which he had devised and used with success.

In the subsequent discussion, Dr. T. G. STEVENS laid stress on the large number of congenital cases which, in his opinion, seldom caused any symptoms.

[We hope to publish Dr. McCann's paper in full in an early number.]

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING HELD FRIDAY, APRIL 7TH, 1916.

The President, DR. LEONARD DOBSON, in the Chair.

THE following cases were shown :—

By Major W. M'ADAM ECCLES.—(1) A living woman with dislocation between fourth and fifth cervical vertebræ (with two diagrams); accident occurred on November 28th, 1915.

By Mr. H. TYRRELL GRAY.—(1) Sarcoma of tibia, male, æt. 10; treated by radium. (2) "Club hand"; congenital absence of radius; bone graft; result (with diagram); female, æt. 2½. (3) Knee-

joint changes in a female child æt. 11 resembling osteoarthritis of adults; ? throat infection; (with diagrams). (4) Central tuberculosis of radius; female, æt. 4; excision of half radius; bone graft; result. (5) Carcinoma of floor of mouth; male, æt. 72.

By Mr. O. L. ADDISON.—(1) Rapidly growing carcinoma of mamma; patient æt. 39. (2) ? Tuberculosis of knee; female, æt. 45.

By Dr. T. GRAINGER STEWART.—(1) Post-diphtheritic paralysis; male, æt. 10.

By Dr. A. J. SCOTT PINCHIN.—(1) Urticaria with dermatographia; male, æt. 10.

By Dr. J. M. BERNSTEIN.—(1) Specific osteitis of tibia; female, æt. 11. (2) Polycystic kidney; female, æt. 40.

By Mr. J. G. PARDOE.—(1) Carcinoma of penis; patient æt. 38.

By Dr. GEORGE PERNET.—(1) Occupation dermatitis; female, æt. 17.

Dr. REGINALD MORTON showed several interesting skiagrams.

THE PRESIDENT, Major W. M'ADAM ECCLES, Mr. H. TYRRELL GRAY, Mr. O. L. ADDISON, Dr. ROWLAND POLLOCK, and Dr. REGINALD MORTON took part in the discussion which followed.

SPECIAL REPORTS.

A NOTABLE PROFESSOR.

AN APPRECIATION OF SIR A. R. SIMPSON, KILLED IN A MOTOR ACCIDENT.

SIR ALEXANDER RUSSELL SIMPSON, Emeritus Professor of Midwifery in the University of Edinburgh, died in the Royal Infirmary of Edinburgh on April 7th from injuries sustained in a motor accident.

Sir Alexander Russell Simpson was born in Bathgate in 1835, was educated in Bathgate Academy and Edinburgh University, where he graduated in Medicine; he thereafter pursued his studies first in Montpellier and then in Berlin. His residence in these cities perfected his knowledge of modern languages, which afterwards he turned to good account as representative of his university at the many international and other congresses at which he was a constant attendant. Like the late Principal Turner and the veteran anatomist, happily still with us, Emeritus Professor John Cleland, he was one of Goodsir's men, strongly imbued with the master's spirit of accuracy. On his return from the Continent, he became assistant to his famous uncle, Sir James Y. Simpson, of chloroform fame. On Sir James's death in 1870, Sir Alexander, the nephew, succeeded to the Chair, giving up his Glasgow practice of five years' standing to carry on his kinsman's work. His task was no light one: not only had he the disadvantage of succeeding a man of world-wide renown, but he had to "make good" as a teacher and operator against rivals of the intellectual calibre of Keith and Matthews Duncan, who were then the bright particular stars of gynecology in the Edinburgh Extra-mural School. Gynecology at that time was just beginning: it consisted mainly in applying wonderfully-shaped pessaries and painting with iodine; but it grew rapidly as a field of large operative procedures till it quickly became a full life's work for anyone. In the growth and development of this branch of medical art, Dr. Simpson took his full share, and at the time of his vacating the Chair he had rightly earned the name of being one of the most skilful operators in that field of surgery. Not only in the practice of his surgical department was he in the forefront, but the literature of the subject from the earliest writings to the

latest paper or pamphlet on gynaecology, here or on the Continent, was thoroughly known to him. He himself contributed largely to the growing mass of material on the new subject, and appreciation of his worth may be noted from the many honours he received from academic authorities here and abroad.

Beyond being a skilled operator and a careful teacher, he was emphatically a human man, as shown in the care of his patients and in his systematic efforts towards bettering the surroundings of student life, especially in fostering kindly personal relations between teachers and taught.

Another side of his full life was his attitude to religion. He was an earnest, deeply religious man. He had marked and active sympathy with the work of Moody and Sankey, and later of Torrey and Alexander. Foreign missions, especially medical missions, found in him a strong advocate and helper; and in the cause of temperance he was a very tower of strength in the north.

He resigned his Chair in 1905, not from any feeling of failing strength or loss of interest in his work, but to give place to "younger if not better men." Recognition of his services to medical science came to him while yet he was quick with life, and none that he treasured more than the congratulatory address which was presented to him from his former students from all over the world. His wife predeceased him a year ago, and he is survived by four sons and a daughter. One of his sons is Professor J. Y. Simpson, of the Natural Science Chair, New College, Edinburgh; a second is the Rev. H. Simpson, the well-known minister of Westbourne United Free Church, Glasgow; and a third is Dr. G. F. Barbour Simpson, Manor Place, Edinburgh.

MEDICAL PROMOTIONS AND HONOURS.

It is announced that the King has been pleased to give orders for the following appointments, and to approve the following rewards, all dated January 1, for services rendered in connection with military operations in the field:—

C.B., Military Division (Additional Members).—Col. Henry Mackenzie Adamson, M.B., Lt.-Col. James Francis Donegan, R.A.M.C.

To be Brevet Colonel.—Lt.-Col. E. Jennings, I.M.S.

To be Brevet Lieut.-Colonel.—Maj. S. Anderson, M.B., I.M.S.

Distinguished Service Order.—Capt. Phirozshah Byramji Bharucha, F.R.C.S., I.M.S.

Awarded the Military Cross.—Capt. Reginald Charles Clifford, I.M.S., Capt. Francis Aidan Robinson, M.B., R.A.M.C., Temp. Lt. Frank Tomsman Simpson, M.B., R.A.M.C.

OBITUARY.

DR. WM. JOHN NOTLEY, B.A., M.D., SMALL HEATH.

By the death of Dr. W. J. Notley, which occurred on April 10th, at Small Heath, there has been removed one of the oldest medical practitioners in Birmingham. Born at Brandon, Norfolk, in 1831, he was the son of the head master of the grammar school of that place, and was destined for the scholastic profession, taking his B.A. degree at the London University in 1862. He eventually decided to enter the medical profession, for which purpose he went to Edinburgh, and in 1880 took his M.B. degree at the Edinburgh University. For a time he practised in that city and coached undergraduates, but in 1883 removed to Small Heath, where he built up a considerable practice, in which he was eventually joined by his son, Mr. John Notley. From time to time he contributed papers to the *Lancet*, the most notable being "On Syncope and the Method of Avert-

ing it," "A Teaching University for London," and "Therapeutic Uses of the Hot Bath." He was for a time president of the Medical Institute, and edited the *Midland Medical Journal*. Dr. Notley was a widely read man, spoke several languages, and upon his retirement from practice about six years ago astonished his friends by setting to work to learn Italian. Failing eyesight, however, put a stop to his studies, and for the last twelve or eighteen months he was totally blind. He leaves a widow, a son, and several daughters.

DR. NICHOLAS J. NORTHEY BRAY, M.R.C.S., BARRY DOCK.

THE death of Dr. N. J. Northey Bray, of Barry Dock, occurred on April 10th. For several years deceased, who was 57, had been in failing health, but had bravely continued to practise. A native of Aberystwyth, Dr. Bray received his medical training at Guy's Hospital, and qualified M.R.C.S. in 1886. He went to Barry 23 years ago, and was very popular and greatly respected among the townspeople. He was surgeon to the Barry Accident and Surgical Hospital. A few years ago Dr. Bray took into partnership Dr. W. Rogers, who enlisted in the Royal Army Medical Corps, and is at present serving as captain with the 42nd West Lancshires, Mediterranean Force. Dr. Bray is survived by his widow, one daughter, and two stepsons and two stepdaughters.

DR. GEO. HY. ANDERSON, M.A., M.D., J.P., LOFTUS, YORKS.

A WELL-KNOWN Cleveland resident, Dr. G. H. Anderson, passed away on April 8th at the age of 73. Educated at Aberdeen, he qualified M.B., C.M. in 1865 and M.D. in 1867. He went to Eston about 1865 as assistant to the late Dr. Keith, whose daughter he married for his first wife. Forty-eight years ago Dr. Anderson went to Loftus, and practised until seven or eight years ago. He was chairman of the local Bench, and had served on the old Local Board, of which he was chairman, and the Urban Council for many years.

DR. J. K. SPENDER, M.D., M.R.C.S., L.S.A., BATH.

DR. JOHN KENT SPENDER, a well-known West of England physician, has died at his residence at Bath at the age of 88. The eldest son of the late Mr. J. Cottle Spender, M.R.C.S., he followed his father's profession, and practised in Bath till his retirement in 1895. As physician to the Royal Mineral Water Hospital, he devoted himself chiefly to the study of rheumatic affections, and occupied a prominent place among specialists in rheumatoid arthritis. He took a leading part in the development of Bath as a place of cure, and wrote several works on Bath waters, on which he was a recognised authority. His wife died over twenty years ago, and of their children, Mr. J. A. Spender, Mr. Harold Spender, and Mr. H. F. Spender have made their mark in London journalism.

LIEUT.-COLONEL C. B. PRALL, M.R.C.S., L.R.C.P., I.M.S.

LIEUT.-COLONEL CEDRIC B. PRALL, of the Indian Medical Service, has died at Mhow, India, at the age of forty-four years. The youngest son of the late Mr. Richard Prall, Town Clerk of Rochester, he received his professional education at St. Thomas's Hospital, and became M.R.C.S., L.R.C.P., in 1892. He then entered the Indian Medical Service. He served in the campaign on the North-West Frontier of India in 1897-8, obtaining mention in despatches, for taking part in the operations on the Samana and in the Kurram Valley, and also at Tirah, receiving the medal with three clasps. He retired in 1899, and in 1902 was appointed Superintendent of Prisons in the United Provinces.

DR. J. S. WARRACK has been appointed Deputy Medical Officer for the Port of London.

LITERARY NOTES.

WE have received copies of the "Medical Register" for 1916, and the "Dental Register" for 1916. In addition to the official lists of registered practitioners of medicine and dentistry, the registers contain a valuable synopsis of the law as it affects doctors and dentists, a subject which is not too widely understood by the two branches of the profession.

* * *

ONE of the earliest of the medical journals in the United States of America to claim the attention and support of the profession in that country, *The Medical Record*, of New York, celebrates its *semi-centennial* this month. Throughout the fifty years of its existence, it has had the same publishers, and but two editors, the first one guiding its straight course for thirty-eight years. In its last weekly issue to hand, it devotes an illustrated plate to portraits of its seven contributors to its first number, bearing such honoured names as Austin Flint, Gaillard Thomas, W. Van Buren, etc., all of whom have passed over to the great majority. Our contemporary has our heartiest wishes that it may live to celebrate its centennial with a like honourable record.

* * *

WE have received from Messrs. J. and A. Churchill a copy of the seventh edition of "A Code of Rules for the Prevention of Infectious Diseases in Schools," issued by the Medical Officers of Schools Association. The little brochure has been thoroughly revised, and there is every indication that an effort has been made to give effect to more modern views on infectious diseases in schools, as is evidenced by the recommendations regarding scarlet fever and diphtheria. Some of the cross references are wrong, but in other respects we have found everything most accurate and all facts succinctly stated. The booklet is extremely practical, and can be recommended to all interested in the prevention of infectious diseases in school. Its price is one shilling net.

* * *

MESSRS. A. AND C. BLACK, publishers of "Who's Who," ask us to announce a "One Hundred Guinea Competition" for war writers, in connection with their other annual publication, "The Writers' and Artists' Year Book." This prize will be awarded to the author of the best book of personal experiences during war-time. The MS. should not be less than 50,000 words in length. It need not deal with actual fighting-line experiences, but may treat of any phase of the war, from the adventures of released prisoners to the wanderings of correspondents over the war zone. The style may be humorous, thrilling, or peculiar, but freshness and originality in presentation are essential. The MS. must bear the name and address of the writer, and be sent to the Editor of "The Writers' and Artists' Year Book," 4, Soho Square, London, by July 31st, 1916. The decision of the Editor will be final, and if no MS. comes up to the standard of publication, the award may be withheld.

* * *

IN a very suggestive article on "The Principles of Giving," by Mr. Andrew Carnegie, in the April number of *The Woman's Magazine*, the author mentions an important department in which great sums of money can be worthily used in the founding or extension of hospitals, medical colleges, laboratories and other institutions connected with the alleviation of human suffering, especially with the cure of human ills. No community will be pauperised by such a gift. What better benefaction than a hospital can be given to a community that is without one, on the condition that its proper maintenance be made a public institution? If hospital accommodation already exists, perhaps no better method for using surplus wealth can be found than in making additions to it. If there is a wealthy man in the land who is at a loss what to do with his surplus, let him investigate the good that is flowing from the establishment of chemical laboratories, no medical college being complete without one.

LABORATORY REPORTS.

PEPTONUM SICCUUM A. AND H.

(Allen and Hanburys, 37 Lombard Street, London.)

WE have received a sample of the above which is prepared for use as a nutrient in the bacteriological laboratory. Analysis shows it to contain over 90 per cent. of soluble matter—albumoses and peptone. It appears well suited for the purpose for which it is intended, and should find a wide field of usefulness in bacteriological work. The eminence of the manufacturers of this new product is a sufficient guarantee to the profession of its purity and reliability in the department for which it is designed.

MEDICAL NEWS IN BRIEF.

The late Sir Alex. Simpson.

AT a meeting of the managers of the Royal Infirmary of Edinburgh on April 10th Dr. MacGillivray, the convener of the Medical Managers' Committee, made a sympathetic reference to the death of Emeritus-Professor Sir Alexander Simpson. His distinguished career, he said, what he did for the Infirmary, and how worthily he maintained the reputation of the name of Simpson in the Edinburgh Medical School, had been most adequately dealt with in the appreciation presented to the Board on his retirement from active work in the Infirmary in 1905. But it still remained for them to convey to his family and relatives an expression of their sorrow and sympathy with them in the sudden loss which they had sustained. He was a great and good man, a strenuous worker, a fine surgeon, and an able teacher, and one whose whole life was devoted to promoting the welfare of his fellow-creatures.

The Care of Clackmannan Consumptives.

DR. ETHEL CASSIE, the interim Medical Officer of Health for Clackmannanshire, has just issued her annual report on the health and sanitary condition of the county for 1915. Special reference is made to pulmonary and non-pulmonary tuberculosis. Of the former 145 cases were treated, 74 being those of insured persons and the remainder uninsured persons; 22 received sanatoria treatment and 22 domiciliary treatment; 10 patients returned from sanatoria fit for work, six were much improved, and two remained at sanatoria at the end of the year. Three deaths occurred during the year, one from each group. Seventy-seven cases of non-pulmonary tuberculosis were notified during the year, as compared with 58 in 1914. Dr. Cassie states that the need for a Tuberculosis Care Committee is very marked, and that some provision for the treatment of advanced cases out of their own homes is urgently needed. Apart from bed-ridden cases, something in the nature of a small labour colony would be of great value, the patients being enabled to live in hygienic surroundings while doing suitable work.

Indian Medical Service Rewards.

IN the House of Commons on April 11th Mr. Tennant, replying to Mr. Malcolm, stated that so far only two field officers of the Indian Medical Service had received rewards, but the lists of rewards so far published only covered the period up to April 15th, 1915. There would shortly be some more covering the period up to the end of September, 1915.

Maternity and Child Welfare in Staffordshire.

A CONFERENCE between the Public Health Committee of the Staffordshire County Council and representatives of urban and rural district councils in the administrative county was held at the County Buildings, Stafford, on April 8th, with reference to a scheme of health visiting in the county.

Dr. G. Reid, the county medical officer of health, said that under the Notification of Births Act health

visitors could be appointed, infant and mother welfare centres established, together with baby clinics where minor ailments could receive attention, and, it might be, lying-in institutions for attending to difficult cases and hospitals where surgical aid might be given to mothers. What the county scheme proposed to do as a start was to appoint health visitors, but every encouragement would be given to the formation of voluntary baby welfare centres by local effort and to the appointment of care committees. The most valuable of these objects was the appointment of health visitors, because of the personal influence they would be able to exercise on the mothers and infants, and to do that the health visitor must be an experienced midwife, tactful and sympathetic. Where centres were formed she would assist in the work and give expert advice and assistance. She would also undertake the visitation of school children who were suffering from ailments, and would visit tuberculous patients in order to ascertain whether the requirements of the tuberculosis officers in regard to treatment were being carried out. Another function, recently introduced by the Local Government Board, was the visitation of patients suffering from measles for the purpose of advising mothers as to the best method of dealing with the sufferers.

Missing Medical Cards.

At the meeting of the Staffordshire Insurance Committee, Dr. Tibbetts called attention to the delay in the issuing of medical cards to insured persons on entering insurance, and he moved that the committee should institute a full inquiry as to the prevalence and causes of and remedies for delay in the issue of medical cards. He said that some patients went to panel doctors for treatment, and when asked for their medical cards could not produce them, and the doctors were thus placed in a difficulty, as they could not legally attend any insured person unless the medical cards were produced. He thought the only way out of the difficulty was that at the time a stamped card was given to an insured person he or she should at the same time be given a provisional medical card for presentation to the doctor if illness came on.

The question was referred to the Medical Benefit Committee for consideration and report.

No Medical Inspection of School Children.

At the monthly meeting of Wick Burgh School Board it was stated that Dr. Bremner, Medical Inspector for School Children for Sutherlandshire, who had taken over the work of Dr. Dick, Medical Inspector for Caithness, in the latter's absence on military service, had abandoned medical inspection of children in both counties, and that no charge would be made for same by the Secondary Education Committee from the time that Dr. Dick ceased work.

No Mating with Germans.

SIR JAMES CRICHTON-BROWNE, speaking at a meeting held by the Sociological Society on April 4th, said that from this time forth, and for a hundred years to come, it should be considered eugenically disgraceful for any English man or woman to marry a German. The history of this war had proved that the Germans were a depraved and morally degraded people, with whom we should have no mating. The Germans were undoubtedly infected with a foul moral taint, and until they had cleansed themselves—and it would take three generations to do that—we should keep clear of them.

Sheffield Cancer Research.

An interesting report of the work that has been accomplished in connection with the Sheffield Radium Institute was furnished at the annual meeting of the Radium Committee, held on April 4th. The movement was set on foot in the spring of 1914, when, in response to an appeal from the honorary medical staffs of the four voluntary hospitals in Sheffield, £8,629 was subscribed for the purchase and employment of radium in the treatment of malignant disease. Owing to the scarcity of radium and the difficulty of securing an early delivery, it was not possible to obtain a supply for Sheffield until the end of 1914, and a further delay

was caused by the necessity for applying prolonged tests to make quite sure that the material purchased was of the amount and quality stipulated for. The amount purchased was equal to 500 milligrams of radium bromide at a cost of £6,891 6s. 8d.

Major Rupert Hallam, Honorary Medical Director, in his report referred to the fact that the first year was the experimental stage, and mentioned that the war had interfered with the obtaining of the laboratory apparatus necessary. Owing to the extensive depletion of hospital staffs, the number of cases treated was not normal, but in spite of drawbacks very useful work had been done, and it was a most hopeful method of treatment for inoperable cancer. In all 127 applications of the radium had been made.

The report of the Executive Committee stated that the actual work of treating with radium began early in March, and had continued uninterruptedly since then. Major Hallam had, they believed wisely, adopted a cautious attitude in speaking of the curative properties of radium in advanced stages of malignant disease. A period of several years must necessarily elapse before an apparent cure could be accepted as a permanent one.

Disease from the Front.

At a meeting of the Bolton-on-Deane Urban Council on April 11th the lady health visitor reported that the district had been somewhat troubled with scabies, which had necessitated the exclusion of several children from school. This disease, she said, was being brought home from the front, and must not be thought to be due to neglect or dirtiness.

Generals' Ages.

THE generals of the German Army are much older than those of either France or Britain. The average age of the British is 53.9 years, that of the French 60.5 years, and that of the Germans 63.5 years. If the royal German generals were excluded the average of the rest of the ages would be 65.66. The average of the Allies is 57.2 years.

State Bread.

THE New South Wales Legislative Assembly has passed, by 27 votes against 25, the third reading of the Bread Monopoly Bill, which establishes a State monopoly for bread making and selling in New South Wales. The proposal has met with a good deal of opposition in the State.

The Royal Society of Medicine.

The library and offices of the Society will be closed from Thursday, April 20th, to Tuesday, April 25th, both days inclusive.

War Babies.

DESCRIBING the special work of the Local Government Board arising out of the war, Mr. Walter Long, the President, in the annual report states that having regard to the allegations which were being made as to the probability of a large increase in the number of illegitimate births in consequence of the presence of large numbers of troops in certain districts, special investigation was instituted in the matter by the Department. A large amount of information was received from numerous sources, and a report on the subject was prepared by the Department. The conclusion was arrived at that the statements which had been made on this subject were generally ill-founded and that there was likely to be little, if any, increase in the number of illegitimate births.

Medical Men and War Service.

In the House of Commons on April 12th Sir John Lonsdale (U., Mid-Armagh) asked the Under-Secretary for War if he was aware that there were a number of practising physicians and surgeons above the age of 45 who would be willing to volunteer for special and general service at home, and thus enable the War Office to free active service men for work at the front; and if the War Office would officially invite all medical men, without limitation of age, to offer their services for the period of the war under a scheme

which would ensure proper recognition and due consideration of the special qualifications of practitioners who volunteered.

Mr. Tennant replied that medical men between the ages of 45 and 55 were being employed as commissioned officers for general service in the United Kingdom. Doctors over 55 might offer their services for local employment to the general officer commanding-in-chief of the command in which they were living, or in which they desired to do duty with troops. He thought the hon. baronet and his medical advisers were really at one in this matter. In other words, the policy should be that the medical men of more advanced years rendered the country the better service by undertaking the care of the civil population, and thus setting free those of military age who were physically fit for duty at home or abroad.

Efficiency of the R.A.M.C.

In the House of Commons on April 12th Mr. R. McNeill asked the Under-Secretary for War if he would appoint an independent committee to examine into and report on the organisation and working of the Army Medical Service at home and abroad.

Mr. Tennant: I cannot undertake action which in my view would only have the effect of dislocating and perhaps disorganising a most efficient piece of mechanism.

Mr. McNeill: Is the right hon. gentleman aware that a considerable number of officers of the Royal Army Medical Corps serving at the front endorse the suggestion which I ventured to make some weeks ago in the House?

Mr. Tennant: As my hon. friend has not thought it right to send me the letters, naturally I could not possibly have the information which he has acquired.

Gifts for Welsh Hospital.

FOUR donations of 1,000 guineas each to King Edward VII. Hospital, Cardiff, for the endowment of beds, have been received from Messrs. Spillers and Bakers (Limited), the Nixon Steam Navigation Company (Limited), Mr. Samuel Instone (of Messrs. C. Instone and Co. (Limited), and a governor of the hospital, on behalf of his brothers, sister, and himself; and Messrs. L. Gueret (Limited). These gifts make twelve such endowments since May last.

Mr. J. Herbert Cory, M.P., forwarded £43 3s. 6d., part of his Parliamentary salary, which he is dividing between the King Edward Hospital and Cardiff Seamen's Hospital.

Doctors and Motor Car Tax.

At a meeting of the Executive Committee of the National Medical Union on April 13th the following resolution was passed:—

"That owing to the great amount of public work, both military and civil, now being done by medical men, and the use of the motor as a means of accomplishing that work being indispensable, it is urged by the National Medical Union that no further burden of taxation be imposed upon the medical profession in connection with the proposed increased taxation of motor-car and motor-cycles, or with reference to the taxation or limitation of the supply of petrol.

It was also resolved that a copy of the resolution be forwarded to the Chancellor of the Exchequer.

Royal Colleges of Physicians and Surgeons of England.

At the quarterly examination in Practical Pharmacy, held in connection with the Royal Colleges of Physicians and Surgeons of England on April 6th and 7th, the following candidates were approved:—

Abdul M. Ahmad, B.A. Cantab; F. E. Bendix, L.D.S. Eng.; I. R. R. Brogden, B.A. Cantab; G. E. Burton, B.A. Cantab; H. A. Chodak, A. B. Dummere, J. R. K. Fenning, G. H. FitzGerald, F. C. A. Frith, T. H. Gunewardene, N. H. Harrison, L.D.S., S. G. Harrison, W. S. Herman, B.A. Cantab, L.D.S.; D. L. Lees, H. S. N. Menko, F. M. Moseley, B.A. Cantab; W. P. Nelson, A. L. Packham, L.D.S., D. F. Pantou, London Hospital; W. H. A. Pratt, J. S. Ranson, C. N. Ratcliffe, J. J. Redelinguys, Florence

M. Rhodes, A. H. Richardson, N. F. Smith, B.A. Oxon; C. H. Terry, B.A. Oxon; W. J. Walters, B.A. Cantab; H. P. Warren, I. G. Williams, B.Sc., S. Winnick, Geoffrey Winter, S. A. Withers, and A. F. Wyatt.

London School of Tropical Medicine.

THE following candidates passed the examination of the London School of Tropical Medicine at the termination of the January-April session:—

Distinction.—W. N. Leak, M.R.C.S., L.R.C.P., and H. Bayon, M.D. (Genoa). (Dr. Leak gains the "Duncan" medal awarded to the student who obtains the highest aggregate of marks.)

Passed.—Miss V. G. Field, L.R.C.P. and S. (Edin.); E. A. Blok, L.R.C.P. and S. (Edin.), L.F.P. and S. (Glas.), L.M.S. (Ceylon); and J. A. Beels, M.D.

MEDICAL WAR ITEMS.

LIEUTENANT JAMES COUTTS, M.B., Royal Army Medical Corps, wounded, is a Glasgow doctor, who took his degree in that city in 1906. He has held the rank of lieutenant since May of last year.

Lieutenant John Moir MacKenzie, M.B., Royal Army Medical Corps, wounded, lived in the neighbourhood of Aberdeen, where he took his medical degree. He has been serving as a doctor in the Army for exactly a year.

Major Robertson Stewart Smyth, M.D., Royal Army Medical Corps, who was invalided home from the front in December last, has died at a nursing home in London. He was the fourth son of the late William Smyth, of Brookfield Lodge, Banbridge, and Mrs Smyth, and was educated at Dungannon Royal School and Trinity College, Dublin. He was captain of Dublin University Rugby Club, and represented Ireland against England in 1903 and 1904, and against Scotland in 1903. He entered the Royal Army Medical Corps in July, 1905, and was promoted captain in January, 1909, and major in October last. He went to the front in September, 1914, and served until December last. He was mentioned in despatches by Lord French for gallant and distinguished service in the field.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

NOTICE. CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our official appointed agents. Indian subscriptions are Rs. 15.12. Messrs Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Capetown. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 25 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DEAR MILK.

In view of the increased price of milk, the Lambeth Guardians have arranged to use more condensed milk, and have ordered 37,500 tins.

ARMY MEDICAL SERVICE.

10,659 MEDICAL men hold commissions in the Army.

THE TRICKSTER.

A DOCTOR stated at Clerkenwell County Court that he had a friend, a doctor, with an artificial leg, who could do trick riding on a bicycle.

BATH WAR HOSPITAL.

BATH War Hospital, at Combe Park, with the Lansdowne Cricket Club ground for recreation, is now open for patients. The Hospital has been built and equipped by the War Office from the designs of Mr. H. B. Measures, F.R.I.B.A., Director of Barrack Construction.

PROOF OF INSANITY!

MORE than £20 in gold was found in the pocket of a mentally deficient patient on his admission to Bishop's Stortford Infirmary.

DR. MULLIGAN (Millbank) will please accept our best thanks for his communication. The other matter has been adjusted as desired.

THE CERTAINTY OF DEATH.

MR. WILLIAM EDWARD BOOTHBY-HEATHCOTE, of Chingford, Essex, and York, who died on December 13th, directed that, after a doctor had certified his death, his heart should be transfixed with a proper surgical knife, and his body buried with the knife in his heart.

DR. A. H. MILLAR (Dundee).—Proof of your article will be sent you this week for correction.

FLYING TO THE GRAVE.

At the dinner of the Aeronautical Society of America, the head of one of the largest undertakings concerns in New York announced that he was preparing to conduct funerals by aeroplanes in the near future. "To be in style," he said, "one must make arrangements to have mortal remains carried on a swift, sombre-hued biplane to the final resting-place." He declared that the roof of his establishment would soon be fitted with a landing-stage for aircraft, and "all conveniences for mourners."

ROYAL FREE HOSPITAL.

MR. ARTHUR DU CROS, M.P., has promised a gift of £7,000 to the Extension Fund of the London (Royal Free Hospital) School of Medicine for Women, thus completing the £30,000 for which an appeal was made.

ANGLERS' RED CROSS GIFTS.

Two Red Cross motor-ambulances, subscribed for by the angling societies of the United Kingdom, will be formally presented in May.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 19th.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Professor B. Moore: Early Stages in the Evolution of Life. Mr. F. M. Duncan: Studies in Marine Biology. Mr. J. W. Purkiss: Some Suggestions regarding Visual Efficiency in the Use of the Microscope and other Optical Instruments.

Vacancies.

- Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North-street, Leeds.
- Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £250 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Secretary.
- Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.
- Victoria Hospital, Burnley.—Female House Surgeon. Salary £160 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon. Secretary, 7 Grimshaw Street, Burnley.
- Township of Toxteth Park.—Assistant Resident Medical Officer. Salary £300 per annum, with board, washing, and apartments. Applications to R. Albert James, Clerk to the Guardians, 15 High Park Street, Liverpool.
- Putney Hospital (Chester Bequest), Lower Common, Putney, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry. Applications to the Hon. Secretary, 198 Upper Richmond Road, Putney, S.W.
- Cambridgeshire Asylum, Fulbourn, near Cambridge.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing and attendance. Applications to the Medical Superintendent.
- The Royal Infirmary, Sheffield.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.
- St. Bartholomew's Hospital, Rochester.—Senior Resident House Surgeon. Salary £300 per annum. Applications to Charles Spyer, Secretary.
- Chesterfield and North Derbyshire Hospital.—Second House Surgeon. Salary £150 per annum, with board, apartments, and laundry. Applications to the Secretary.

Appointments.

- GOTELEE, H. E., M.R.C.S., L.R.C.P., District Medical Officer of the Newton Abbot Union.
- JOYCE, H. W., L.S.A., District Medical Officer of the Mansfield Union.
- LINDSAY, JOHN KERR, L.R.C.P. & S. Edin., L.F.P.S. Glasg., District Medical Officer to the Bristol Board of Guardians.

- MAINS, J. H., L.R.C.P. Lond., Certifying Factory Surgeon for the Clackmannan District, co. Clackmannan.
- PROCTOR, S. P. P., M.B., Ch.B. Edin., District Medical Officer of the Chesterfield Union.
- TIBBES, W., L.R.C.P. Edin., M.R.C.S. Eng., District Medical Officer of the Nottingham Parish.
- TURNER, WILLIAM, M.S., F.R.C.S., Surgeon to In-patients to Westminster Hospital.

Births.

- FAULKNER.—On April 14th, at The Rectory, Stanford-le-Hope, Essex, to Captain Cyril D. Faulkner, R.A.M.C., and Mrs. Cyril D. Faulkener (née Hilda Marion Russell)—a son.
- MAY.—On April 12th, at The White House, Sonning, Berks, to Dr. and Mrs. Norman May—a son.
- POLLARD.—On April 10th, at Southsea, Mary (née Coghlan), the wife of Capt. A. M. Pollard, R.A.M.C., of a son.
- REICHAERT.—On April 4th, at Dorset House, Ewell, Surrey, the wife of E. N. Reichardt, M.D. Lond., of a son.
- WHEATON.—On April 9th, at 17, Rastell-avenue, Streatham Hill, S.W., the wife of S. W. Wheaton, M.D., F.R.C.P., of a daughter.
- WILLIAMS.—On April 12th, at Bankside Nursing Home, Hendon, Nina (née Humphreys), the wife of Captain Charles Eustace Williams, R.A.M.C., of a daughter.

Marriages.

- CRAWFORD—JENNY.—On April 12th, at Christ Church, Woburn Square, London, Thomas Maitland Crawford, Lieutenant, R.A.M.C., seventh son of the late Sir Thomas Crawford, K.C.B., (late Director-General, A.M.D.), to Mabel Gertrude Louise Jenny, only daughter of the late Jaques Jenny and Mrs. Jenny, of London.
- DENHAM—BRIGGS.—On April 11th, at Trinity Presbyterian Church, Kensington, Captain Charles Holmes Denham, R.A.M.C., elder son of J. Knox Denham, J.P., F.R.C.S., of Dublin, to Irene, youngest daughter of the late James Cronshaw, of The Firs, Cheadle, Cheshire.
- HAMILTON—ZIEGLER.—On April 14th, at St Saviour's Parish Church, Alexander Keith Hamilton, Temp. Captain, R.A.M.C., to Frances, second daughter of the late W. H. Ziegler, and of Mrs. Ziegler, Oxtou, Cheshire.
- MACINTYRE—LYMBERY.—On April 6th, at Ashbourne Parish Church, by Revd. Canon Morris, M.A., David Duncan Fraser Macintyre, M.B., Surgeon, R.N.V.R., and Board of Trade, to Sarah Elizabeth Lymbery, late Queen Alexandra's Royal Naval Nursing Service.
- RAIKES—LEWIN.—On April 6th, at St. Mary's, Plaistow, Bromley, Kent, Captain John Walter Rakes, R.E., second son of Canon Rakes, of Gondhurst, to Phyllis Margaret, daughter of Lieutenant-Colonel W. H. Lewin, Indian Army, of Dorunda, Bromley, Kent.
- SACKVILLE MARTIN—GLADSTONE.—On 3rd April, at St. Paul's Church, Valetta, Malta, Captain James Sackville Martin, R.A.M.C., of Leigh, Lancashire, to Florence Gladstone, eldest daughter of the late C. E. Gladstone, Bengal Civil Service, and Mrs. Gladstone, Roseneath, Jersey.
- SMITH—MALLINSON.—On April 11th, at Walthamstow, Philip Smith, Captain, R.A.M.C., of Bromley, Kent, to Evangeline Dorothea, younger daughter of William Mallinson, J.P., The Limes, Walthamstow.
- WATSON—MONSON.—On April 15th, at Holy Trinity, Kingsway, W.C., Dr. C. E. S. Watson, S.M.O., of the West African Medical Service, youngest son of Mrs. Watson, of "Southolme," Forest Hill, S.E., and the late George Peregrine Watson, of Demerara, to Kathleen Rowena, youngest daughter of Edward Monson, J.P., F.R.I.B.A., and Mrs. Monson, of Grosvenor House, Acton Vale, W.
- WILSON—MOTTERSHALL.—On April 12th, at the Church of St. Bartholomew the Great, London, Walton Ronald Wilson, Lieutenant, R.A.M.C., only son of Dr. and Mrs. Wilson, Forest Hill, to Emily Constance Mottershall, niece of Mr. and Mrs. Walter Southern Hunt, "Castle Mount," Eastbourne, formerly of "Castle Mount," The Park, Nottingham.

Deaths.

- BRICE.—On April 5th, at Swansea, Major Ernest Brice, R.A.M.C., M.R.C.S., aged 52.
- COLE.—On April 11th, of wounds received on March 22nd, Major A. H. Cole, F.R.C.S., third son of Dr. H. H. Cole, M.D., F.R.C.S. Eng., of Leamington, aged 44 years.
- CROSBY.—On Friday, April 7th, after a few days' illness, Alderman Sir Thomas Boor Crosby, Alderman for the Ward of Langbourne, in his 86th year.
- FITZGERALD-POWELL.—On April 5th, H. FitzGerald-Powell, M.D., F.R.C.S., Surgeon, Throat Hospital, Golden-square, W., of 5 Harley-street, Cavendish Square W.
- HANBURY.—On Tuesday, April 11th, at the Manor House, Little Berkhamstead, near Hertford, Cornelius Hanbury, in his 89th year.
- PRALL.—On Wednesday, April 5th, at Mhow, India, Cedrio Barkeley, Lieutenant-Colonel, I.M.S., youngest son of the late Richard Prall, Town Clerk of Rochester, aged 44 years.
- SPENDER.—On April 14th, at 34 Marlborough Buildings, Bath, J. K. Spender, M.D., aged 86.
- TANDY.—On April 10th, at Mount Pleasant, Northam, N. Devon, Edward Ord Tandy, Colonel, I.M.S. (retired).

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Tax on Mineral Waters.

THE Chancellor of the Exchequer has, I am glad to see, withdrawn the railway tax, which, as I pointed out the week before last, was by no means unobjectionable from the point of view of the public health. It is very much to be hoped that he will see his way to withdraw the proposed duty on imported mineral waters. Such a duty cannot be expected to contribute anything of importance to the revenue, for the reason that its chief effect would be to smother the trade. Before the war the bulk of the trade in bottled mineral and table waters was in the hands of enemy countries. In spite of the disappearance of German competition, the circumstances of the war have already pressed heavily upon the trade from France. Freights have increased and the price of bottles has risen, male labour has disappeared and consumption has diminished. Our friends were, nevertheless, in the fairway of capturing the trade. The duty will completely abolish the advantage which the French waters were thus beginning to obtain, so that, if only on international grounds, it is objectionable.

Gaseous and Others.

It is also objectionable on medical grounds. Mineral waters are not a pure luxury. Even the bubbly waters, especially when, as in the case of Perrier, they are bubbly by nature, have, in the opinion of many, some very conspicuous dietetic merits. Many of the French waters are, however, medicinal waters, and they are medicinal in a way that no one has ever claimed to be able to imitate in the laboratory. Vichy water, for example, whose chief ingredient is bicarbonate of soda, produces effects to which ordinary solutions of that salt cannot pretend. The waters of Contrexéville and Vittel admittedly possess curative properties in renal affections, the secret of which no chemical analysis has yet revealed. Evian-Cachat water is a diuretic water of real efficacy, and it shares with the water from the Source des Deux Reines at Aix-les-Bains a reputation in gouty, rheumatic and arterial diseases with which none of our home waters can pretend to compare. It is not in the public interest that the importation of these waters should be checked. They are therapeutic

and prophylactic agents of great value, for which there are no substitutes in these islands.

Patent Medicines.

IF the Chancellor of the Exchequer is "out" to kill a trade by a smothering duty, he might surely once more turn his attention to patent medicines. In last week's issue there appeared a letter on this subject which deserves careful perusal. It is from the pen of Mr. Henry Sewill, than whom no one has a more intimate and peculiar knowledge of the whole question. Mr. Sewill says that "these condemned concoctions were enough to render the patent medicine trade, as a whole, an improper source of revenue." With this I cannot altogether agree. It appears to be an axiom of British law that, in matters of health, a man is at liberty to trade on the credulity of the public. To abolish this axiom would require a revolution; to abrogate it would provoke a revolt; but there seems to be no reason why those who benefit by this form of liberty should not contribute handsomely to the State which confers it. It is, I fear, too much to ask of any Government that it should protect the British public to the point of abolishing patent medicines; but it is quite reasonable to demand that both purveyor and consumer should pay for the luxury, in the one case of deluding, in the other of being deluded. In these days of new-found fervour for child welfare, might it not be a good thing to give a deterrent legislative eye to the sedatives which nurses secretly buy, and surreptitiously administer to their innocent charges?

Dogs.

IT is to be hoped that a further effort will be made to induce the Chancellor to cull some of his much-needed money from the fertile, futile and effeminate field of the town-dwelling dog-owner. Here is a luxury, a most unneighbourly one, a luxury fraught with serious potential dangers to the public health, a luxury which is in the highest degree wasteful of the food for which many human beings are vainly crying out, a luxury which makes unnecessary work at a time when labour is scarce; yet nothing is done to make it contribute any more in war time than it did in peace-time. I don't know who is responsible for the placards which have the self-satisfied effrontery to tell people what is,

and what is not, "good form," nor who pays for them; but this I do know, that if the ingenuity and money which they represent were directed to a campaign against the useless and dangerous extravagance of dogs in large towns, some real good to the community might ensue.

In the *Daily News and Leader* for April 12th there is published the correspondence between Mr. Tennant, **Mr. Tennant** and **Mr. Barker.** the Under-Secretary for War, and Mr. H. A. Barker, "the well-known bonesetter," which is reproduced in another column. The first thing that strikes one about this correspondence is the personally sympathetic tone which graciously irradiates from Mr. Tennant's letter. That may be an example of "the new style" evoked by the war; it is certainly, to say the least, most unusual in official letters from a Government Department. Mr. Barker, in his reply, says: "As you may perhaps be aware, the whole of my career has been devoted to a branch of therapeutics which—on the admission of some of the most distinguished practitioners of the day—has been neglected by the surgical schools." It would be interesting to know the names of these "most distinguished practitioners," also when and to whom they have made these engaging admissions. At the end of the letter Mr. Barker writes as follows: "I cannot but strongly protest against the professional prejudice which really alone bars the way to my rendering the service I desire, but which does not prevent medical men and their families from seeking privately, at my hands, the relief they are officially withholding from others." Again I say it would be interesting to have some names and testimonials.

Qualification and Unqualification. It is not that names and testimonials would in any degree affect the principle, which is, indeed, sufficiently well understood both by the profession and by most sane members of the public to require no insistence from me. The question is purely one of qualification or no qualification. Both states have their advantages and disadvantages, but you must choose which you will have. In this, as in most other matters, you cannot have the best of both worlds; you cannot have the world of unqualification plus official recognition, any more than you can have the world of full qualification with the freedom from responsibility and disciplinary measures which the absence of a diploma confers. That Mr. Barker should wish for the best of both worlds only shows him to be as human as the rest of us; the extraordinary thing is that his request in this matter should be taken seriously and treated sympathetically by a Minister. Imagine an "unqualified lawyer" presenting a request for legal employment to the Lord Chancellor, one of the Law Officers of the Crown, or one of His Majesty's judges; and picture to yourself, if you can, the dignitary so approached writing thus to the unqualified applicant: "A refusal to accept your offer ought not to be considered as anything in the nature of a slur on your abilities." Yet, if we may believe the *Daily News and Leader*, these are the very words used by Mr. Tennant, the Minister, to Mr. Barker, the bonesetter.

The Profession and the Authorities. It is surely high time that our long-suffering profession were represented in Parliament by someone with the energy and courage to characterise this kind of thing as it deserves. If the profession were really the trade union which Mr. H. G. Wells says it is (which it is not at present, but which it very likely will be driven to be in the future) a letter such as this of Mr. Tennant's would immediately be followed either by an apology or a strike. Governments and public officials must not imagine that they will always be able to play fast and loose with a self-respecting, self-sacrificing profession, whose members conform to Governmental regulations at the daily risk of their lives, and who ask in return no more than a recognition of their status and an acknowledgment of the value of their services to the community. As things now are, what happens? At a time when every informed person is glad and proud to eulogise the services of the profession to the military, and to the civil population, the Minister who is, in a sense, one of the heads of the very service to which medical men have by common consent shown the greatest devotion and rendered the most invaluable aid, is found publicly bowing and scraping to an unqualified "bonesetter," thanking him for his offer, "which I do with sincerity," and hinting that, did the military regulations allow, the said "bonesetter" would be given a free hand upon the suffering soldiery. It is nothing short of an outrage.

Orthodoxy and Dissent.

It is bad enough that the nonsense of unqualified practice should obtain support in the otiose *parvenu* circles from which Mr. Tennant derives, but it is a grave scandal that it should penetrate into official or semi-official pronouncements. We can afford smilingly to concede to certain over-fed and over-exposed ladies the luxury of being persuaded into dietetic and other forms of restraint by Christian Scientists and Higher Thoughtists; we can look with indulgence upon the degenerates who listen with triturtatic fervour to Mr. Eustace Miles' pseudo-scientific siftings from the scullery; even as we can hearken with amused equanimity to the plaintive treble of the conscientious objectors who follow Mr. Stephen Coleridge when he valiantly advances against vaccines. These are dissenters who, whether their dissidence be mercenarily motivated or otherwise, are clearly entitled to such indulgence as is due to dissent openly declared. But an Under-Secretary for War stands for orthodoxy, and whatever be the private predilections of a Mr. Tennant, the public pronouncements of a Minister should reveal no suspicion of heterodoxy. It is a pity that Mr. Tennant should have been led into a departure from this rule, which, although it is unwritten, is nevertheless obviously salutary; and it ought to be binding.

SINAPIS.

MISS GERTRUDE LANGTON, of Liverpool, left £300 each to the Bluecoat Hospital, Liverpool, and the Infirmary for Children, Liverpool.

OF CHILLS AND CATCHING COLD.

THE appeal to antiquity is a potent factor in the life of the cultured; and respect for authority, whether based on reason or otherwise, is the lodestar of more than one-half of Christendom. In matters artistic the pre-eminence of the ancients is still pre-eminent; in matters theological the authority of the Churches still dominates. In matters scientific, however, neither the wisdom of the one nor the influence of the other can be permitted unchallenged recognition; nor can we even admit that the saws and dicta of our forefathers in medicine shall be allowed to escape the busy sieve of advancing knowledge. Prejudices and preconceived notions everywhere die hard, and nowhere harder than in pathology and practice. Of this, no better example could be adduced than the attitude which is still adopted by the public, and by the profession which in these matters educates the public, towards the commonest of common ailments—namely, the common cold.

An attack of nasal catarrh or coryza, more often than not, is ushered in by a feeling of chilliness. The immediately succeeding attack, being a "*post hoc*," became in the minds of the microbically uneducated a "*propter hoc*," and a "chill" was asserted to be the cause of that which was christened a "cold." This topsy-turvy reasoning gave rise to a practice which of all hygienic heresies has proved the most devastating to the human race. The warm, still atmosphere of the house, the warm flannel clothing of the child, the closed door and the hermetically sealed window of the office and the railway carriage, the poison-charged air of the public building and the workshop—all of these and similar have contributed and created and circulated all manner of deadly infectious disease, of which the most frequent is by far the most deadly—the pale and pitiless spectre-eyed tubercle. The hand that rocks the cradle rules the world. The unwashed hand of the ordinary nursery nurse, physically and morally the most insidious and tyrannical enemy of every rising generation of the upper human race, has been guiding our hygienic practice from times immemorial, apotheosing chills, eschewing draughts, closing our nursery windows, over-feeding and over-clothing our children, and to-day, though we are tardily awakening to the appalling waste of infant and child life, we still turn a blind eye to perhaps its most potent cause. The disingenuous wonder why, and appoint Royal Commissions. But the reason is here, to hand. The nursery nurse believes in chills as a cause, and colds as a consequence. Her practices are in keeping with her theories. There is joy and rejoicing among the microbes, and death and devastation among the children.

The nursery nurse has unfortunately received much support from the profession. The advice of the shrewd, but not over scrupulous teacher, who advised his students, when they should find themselves in doubt as to the diagnosis of a childish ailment, to take the opinion of the nursery nurse and acquiesce therein, has been followed all too slavishly. Nevertheless, during the last twenty years occasional

voices have been raised against the supremacy of chills. Logically, the successful open-air treatment of pulmonary tuberculosis was its death warrant, but the sentence has not been carried out. As a nation we are not given over to logic; we prefer to muddle through to the point where we adopt panic panaceas. But the execution of the death sentence on the chill causation of disease in general, and colds in particular, cannot now much longer be delayed. The text-books are beginning to speak, and, if we may judge by one of them, the most recent, they will soon be yodelling in no uncertain unison.

The new edition of Sir St. Clair Thomson's book (a) contains a chapter "On Taking Cold," which sets forth, not argumentatively as though there were a ghost to be laid, but pontifically as though no discussion were admissible, the scientific aspect of this important matter. The chapter is in every way admirable; it will certainly be largely quoted—by some frankly, by others furtively; and having regard to the authority of the writer there is hope that the profession will now adopt the true faith which may gradually permeate the public, and eventually attain that grim citadel of tyrannical ignorance, which is the nursery of the well-to-do.

Defects and disease in the upper air passages are a very powerful cause of disease in other parts; not only in the lower air passages, but in the intestinal tract and elsewhere. In medicine, no speciality is, even approximately, an exclusive study. As Courty says in the passage which is quoted on the fly-leaf of this book, "*La spécialité est le degré le plus bas de l'art, lorsqu'elle n'est pas fécondée par les connaissances générales; elle en est la perfection lorsqu'elle est le couronnement de la science. Il faut finir au lieu de débiter par elle.*" The interdependence of the various parts of the human organism is nowhere more forcibly exemplified than by the length of reach of this comparatively recent speciality, with which, from the fact that he served a long and arduous apprenticeship to general practice, no one is better qualified to deal than Sir St. Clair Thomson. If ever a special treatise was "*fécondée par les connaissances générales*" it is this one; indeed, if the book had been called "The Influence of the Upper Air-passages upon Health and Disease" no one could have cavilled at the title. When we consider that the normal nasal passages contain the filtering ground for the air which, on reaching the lungs, is to debarras the blood of its impurities, it is not difficult to realise that the physiological integrity of that airway is among the most important factors in the formation of stamina and the maintenance of health. When we have studied some of the well-drawn diagrams of the nasal cavities and accessory sinuses with which this book is so well and profusely supplied, we awaken to the fact that the individual evolution of the brain must depend, in part at least, upon the proper development of the bones which bound these spaces. To gaze upon the pictures of the pectoral effects of

(a) "Diseases of the Nose and Throat, Comprising Affections of the Trachea and Oesophagus," by Sir St. Clair Thomson, M.D., F.R.C.P., F.R.C.S. Lond. Cassell and Co., 1916.

nasal obstruction is to appreciate the fact that the blockades of adenoids, polypi, deviations of the septum, and the like, are among the most efficient means of preparing the human soil for the reception of the eagerly crouching microbe. Liberty of the nasal passages is worth fighting for, and Sir St. Clair Thomson fights valiantly.

As a text-book on the subject of which it treats with so much lucidity, Sir St. Clair Thomson's book deserves unqualified commendation. For lucidity is the keynote of its appeal. From the perusal of any section the reader carries away an indelible picture of what he has been told, and the telling not infrequently includes phrases which strike, impress and remain. The subject ramifies—it ramifies into territory undreamed of when the speciality was first evolved—but the lines of ramification are scientifically illuminated by clear thinking and unusually graceful writing.

L. B. W.

CURRENT TOPICS.

Incurable Soldiers and the War Office.

MR. H. J. TENNANT, Under-Secretary for War, has addressed the following letter to Mr. H. A. Barker, the well-known bonesetter, who asked: "If the Army medical authorities had definitely refused to accept his services, that at least those cases which came within his sphere of work and which had been finally relinquished as incurable might be placed under his care":—

"Dear Sir,—I have to thank you for your two letters of the 30th of last month. I find myself in a position of no small difficulty, which I think you must be able to realise. A refusal to accept your offer ought not to be considered as anything in the nature of a slur upon your abilities, and yet anything but a refusal would open the doors for the admission of many others whom I am sure you would consider to be quite undesirable persons.

"It is, indeed, impossible for so great a machine as the Army to proceed upon lines which you might call unofficial. Any endeavour to do so would lead us into an almost hopeless position. If you would be good enough to try to visualise our position, I do not think you will be able to come to any other conclusion.

"In these circumstances I have no other course open to me but to thank you for your offer, which I do with sincerity, and to express my regrets that I can hold out no hope that the decision which I announced is otherwise than definite and final."

In reply, Mr. Barker wrote:—"I fully understand and sympathetically appreciate the difficulties which confront you in your official position respecting my offer, but I do not see that any acceptance of my services need necessarily 'open the doors for the admission of others,' unless they could produce the evidence in support of their claims that has been presented in support of mine.

"As you may perhaps be aware, the whole of my career has been devoted to a branch of therapeutics which—on the admission of some of the most distinguished practitioners of the day—has been neglected by the surgical schools. Such neglect has been, and is, responsible for an appalling amount of avoidable suffering, and it is this suffering amongst soldiers and would-be soldiers that I have sought permission to relieve. If surgeons themselves were affording this help I should be silent; but as they emphatically are not doing so, I cannot

but strongly protest against the professional prejudice which really alone bars the way to my rendering the service I desire, but which does not prevent medical men and their families from seeking privately at my hands the relief they are officially withholding from others."

A Doctor's Heroism.

UNDER the above title a paragraph has been going the rounds of the daily papers. It states that the Rev. Bernard J. Snell, M.A., B.Sc., has had a thrilling incident told to him in a letter written by his son, who is a wounded officer in France. Some wounded men were in an almost inaccessible place, and the doctor was forbidden to go to them. But he ran the gauntlet of 300 yards in the open and reached the party of wounded. He amputated two limbs and bound up the wounds of the other men as best he could. Finding that the best service he could render was by going back, he rushed across the open, and, just as he was reaching the home trenches a German bullet struck him in the heart, and he fell into the arms of Mr. Bernard Snell's son. "Oh, the cloud that came over all of us," said the writer, "when we realised that the man had given his life, not called by duty, but only by heroism, and by that unspeakable, indescribable impulse that dwells in men at their best!" We take it that the medical man was subject to military discipline, and if so, that he disobeyed orders. Nevertheless, the deed was heroic. The wounded officer, however, should realise that the doctor gave his life because "called by duty," the high conception of duty as realised by the medical profession. Why should the name of the fallen hero not be disclosed?

The Role of the Obstetrician.

WE flatter ourselves that we are not easily startled, but we must confess that for once our judicial calm has been disturbed by a communication from across the pond. We have always believed firmly in the obstetrical efficiency of nature. We have set ourselves to aid her efforts with as little interference as possible unless some untoward complication called for further action on our part. We have pinned our faith to the natural order of things and have sought to imitate them in our methods. And now comes this bolt from the blue in the form of a paper by Dr. Charles B. Reed, of Chicago, published in a recent number of *Surgery, Gynaecology and Obstetrics*. Our watchful waiting is an evasion of responsibility, our masterly inactivity but a paraphrase of timidity, indolence, and dubiety. We are to impose our will upon each pregnant woman until the whole process of childbirth works in strict harmony with the principles of modern science. Having seen the woman, we must appoint the day upon which we shall consider the child to be mature. The day arrives and we induce labour—"The apple is plucked at maturity, why not the child?" We control the pains, the woman's consciousness, the advancement of labour, and as soon as possible with our forceps we extract the ripened fruit. The woman is saved the tiresome and uncertain wait for the day of her delivery, at the appointed time labour is shortened so that she may suffer no exhaustion, while the mythical dangers of interference—septic infection, irregular contractions, avoidable lacerations—may all be completely ignored. Reed quotes 100 cases treated in this manner. The fact contained in his opening sentence that "the physiological duration of human pregnancy is as yet known only approximately," has forced him to work upon an average, and he determines the maturity of the foetus *in utero* by a

measurement of its length, the object being to avoid labour with a post-mature child, as he considers 70 per cent. of infants who weigh over 8 lb. at birth. Yet, as the weight of the infants in this series varied from 5 lb. to 10 lb., the average being 7.7 lb., the method does not appear to accomplish its object with very great accuracy. In 23 of these cases forceps were applied in accordance with his opinion that "the courageous use of forceps is safer for mother and child than a timid reliance on the aimless powers of nature." We admire Mr. Reed's courageous self-confidence, but we agree with the remark of the dear old lady who, having read a newspaper notice of a birth, with the words "by cable" appended, declared that she thought the old-fashioned way better.

Time in Surgery.

UNDER the auspices of a perfect asepsis, and with the collaboration of a specialised anaesthetist, the surgeon is sometimes inclined to forget that an operation may still be a trying experience for the patient, and that the adverse effect will be in direct proportion to the length of time required. Mr. R. P. Rowlands, of Guy's Hospital, has written a much-needed reminder of this fact, published in a recent number of the *British Medical Journal*. He pleads for a more complete preparation before the operation is begun, also for a simplification of all *technique*, that the progress of the work may be delayed as little as possible. Important as this is, there is another delay which is far more dangerous—that is, the delay in diagnosis and the decision to operate. Mr. Rowlands quotes in illustration two cases of acute appendicitis, the one diagnosed and operated upon within thirteen hours of the onset, whose convalescence ended in complete recovery three weeks later; the other case neither diagnosed nor operated upon until the tenth day, followed by many months of severe illness and misery. Of acute conditions, appendicitis and intestinal perforation are the best examples of the need of haste in operative interference. The removal of an acutely inflamed appendix within twelve hours of the first symptoms is no more risky than its removal during the quiescent period, while a few days later the complications of abscess, peritonitis, or perforation will increase the dangers manifold. Of chronic conditions, cancer is quoted as the standing example of the danger of delay. Were diagnosis generally improved, inoperable cases of cancer would not be met.

The Motor Tax.

WE are far from continually advocating the rights of the medical profession as though it were to constitute a species of religious caste. Yet upon an occasion when their services are still in demand, and are in many instances increased, by partial attendance upon members of the military profession; when their expenses are advanced without their being able to put any premium upon their own labours; when time and life itself depend upon the rapidity of their movements; under such circumstances to rope them in with the general community in the matter above indicated is surely unfair. To compensate for increased taxation on commodities the merchant raises his prices. This is not possible for the professional classes. A sum of even eighteen pounds per annum is a serious matter for many struggling practitioners. If they decide to dispense with their conveyance, the lives of their patients and their own health and consequent efficiency are placed in jeopardy. The medical man does not employ a motor car for amusement. He employs it for *efficiency*—to reach his clients as quickly as

possible—and if for any selfish reason at all, to prevent his own breakdown from physical exhaustion.

Supplies.

THE state of dereliction in which the trade of medical and scientific appliances has been left by the war calls for some attempt at amelioration. Not only more elaborate pieces of apparatus, but even such a simple commodity as glass tubing can no longer be procured with any reasonable facility. At first we were told that such circumstances were due to the imperfect and hampered traffic and shipping. To-day it is because all workers in such material are engaged in manufacture for purely military purposes—if not actually recruited. We think that preferential treatment might well be shown to the medical man, and more especially to hospitals, many of which are largely occupied by inviolated military. Their supplies of chemicals and stuffs, both for ward and laboratories, *should* be guaranteed. That they are not already so, may more than they are not to be so, is not to be blinked at by the pretext crisis. It is inefficiency of public administration—simply that—nothing more nor less. Let them be circularised, and an approximate estimate arrived at, to be subsequently met as far as may be possible.

Septicæmic Diarrhœa in Measles.

OUR Paris correspondent writes that Professor Marfan has recently drawn attention to this serious complication in measles. It is especially frequent in children under four or five years old, but may appear in older children, and even in adults. The diagnosis of septicæmia is established by elimination of the different causes capable of giving a rise of temperature (broncho-pneumonia, otitis, etc.) Septicæmic diarrhœa is nearly always catarrhal, although Trousseau has mentioned a dysenteriform variety in certain epidemics. The prognosis depends much more on the septicæmic state than on the intensity of the diarrhœa. He remarks that the higher the temperature the worse the general state of the patient and the more serious the septicæmia. He urges the importance of noting the state of the liver; if this is enlarged, the case will almost certainly end fatally. Treatment consists in a water diet for about six hours, then milk diet with rice-water. Tepid baths and inunctions with collargol.

PERSONAL.

DR. J. H. MAINS, of Clackmannan, has been appointed Certifying Surgeon under the Factory and Workshop Acts, in succession to Dr. W. Murray (resigned), for the district of Clackmannan.

MISS RACHEL MACKENZIE, M.B. (of Walthamstow) has been appointed part-time medical officer by the Tottenham Urban District Council. The Council also appointed three women health visitors.

THE Royal Humane Society has decided to present a bronze medal to Dr. Alan M'Dougall, the medical superintendent of the epileptic colony at Warford, near Alderley Edge, for his heroic rescue in connection with the ice disaster in November, when eight persons were drowned.

AT the General Quarterly Court of Governors of the Royal Hospitals of Bridewell and Bethlem, held on April 17th, the Lord Mayor, Colonel and Alderman Sir Charles Wakefield, was appointed President in the room of the late Sir Thomas Boor Crosby, M.D., and Lieutenant-Colonel A. J. Copeland was for the 28th year appointed Treasurer.

CLINICAL LECTURE

ON

EXTRA-UTERINE GESTATION.

By C. E. PURSLOW, M.D.Lond., M.R.C.P.Lond.,

Honorary Obstetric Officer, Queen's Hospital; Lecturer in Midwifery and Diseases of Women, University of Birmingham; Consulting Surgeon, Birmingham Lying-in Charity and Maternity Hospital.

EXTRA-UTERINE gestation is the implantation and growth of the ovum in some other place than the uterine cavity. Cases, however, of pregnancy in an ill-developed horn of a bi-cornuate uterus are attended by the same symptoms and dangers as true cases of extra-uterine gestation, and are generally included in descriptions of the latter; to cover these, the term "ectopic" may be used instead of "extra-uterine."

Extra-uterine gestation in an enormous preponderance of cases occurs in the Fallopian tube, and, at one time, the occurrence of primary abdominal and ovarian pregnancy was denied, but several undoubted cases of the latter have now been recorded, and lately one or two cases of primary abdominal pregnancy have been published by acknowledged authorities.

As regards the ætiology of tubal gestation there is still much dispute. At one time it was thought that it was due to damage to the lining membrane or the lumen of the tube by previous inflammation; but, since then, several investigators have reported cases where the most careful examination has failed to disclose any evidence of previous lesion in the tube, and many now regard the condition as an accident, the ovum happening to stray into some blind diverticulum or to be caught in the folds of the mucous membrane. If there is only delay after fertilisation, it is easy to understand how the trophoblast of the ovum, which is undergoing rapid development, will be able to form an attachment to the wall of the tube.

Pregnancy is commonest in the ampulla of the tube, and we will take this as the type. When this occurs, the trophoblast of the ovum excavates the wall of the tube, and the ovum becomes embedded under the mucous membrane in the same way as is now proved to occur in normal uterine pregnancy.

The following occurrences may then take place:—
Pregnancy may go on to term in the tube. This is doubtful, though some writers consider that it has been proved.

The pregnancy may be disturbed at an early date by hæmorrhage into the tissues of the ovum, resulting in the death of the fœtus and leading to the formation of a tubal mole. This forms one of the varieties of hæmatosalpinx, and the blood may undergo complete absorption, or, very rarely, may become infected and suppurate, forming a pyosalpinx.

Tubal Abortion may occur. This may follow the formation of a tubal mole, or may occur as a primary lesion. In either case the fœtus dies. This occurrence is attended by hæmorrhage into the peritoneal cavity, resulting in the formation of a hæmatocele.

The tube may rupture. Several results may follow from this: A very large amount of blood may be effused into the peritoneal cavity, and the patient may die from loss of blood within a few hours. Fortunately, this result is uncommon.

In the majority of cases the patient survives the rupture, and then the fœtus may go on living. This

is a rare occurrence, and will only be possible if the placenta or chorion remain attached to the wall of the tube, and if the amnion remains intact, though the latter proviso is denied by some authorities. The rupture may take place into the peritoneal cavity or through the part of the tube uncovered by peritoneum into the broad ligament. In either case the fœtus may live to term; in the first instance we should have a secondary abdominal pregnancy, and in the second an extra-peritoneal or broad-ligament pregnancy. The former is the commoner, though both are very rare conditions. If the fœtus goes on living to term, it may be extracted alive by operation; if that is not done it dies; it may then remain quiescent in the abdominal cavity for an unlimited number of years. In these cases it has become calcified, and is called a lithopædion; in other cases the sac may become infected, usually from neighbouring bowel; suppuration then occurs, and the fœtus may ultimately be discharged, piecemeal, through fistulous openings to the skin or neighbouring viscera. Both these occurrences are very rare.

A much more common event is for the fœtus to die at the time the tube ruptures, and for the effused blood to form a hæmatocele, which will be intra- or extra-peritoneal, according as to whether the rupture has been into the peritoneal cavity or into the broad ligament. In either case the effused blood may absorb, or, much more rarely, may suppurate.

The Symptoms of extra-uterine gestation are often atypical, and, in many cases, most puzzling. It should be borne in mind that when we speak of the symptoms of tubal gestation we usually mean the symptoms due to some of the disturbances of the pregnancy which have been mentioned above, as until one of these has occurred there is, as a rule, nothing to call attention to the case or to distinguish it from ordinary uterine pregnancy.

The three most constant symptoms of extra-uterine pregnancy in my experience are:—

- (1) Irregular or constant slight uterine hæmorrhage.
- (2) Intermittent attacks of severe abdominal pain.
- (3) The presence of a tender mass on bimanual examination.

Amenorrhœa is usually spoken of as one of the leading symptoms, but in a large percentage of cases (some say 30 per cent.; I should say even more) it is absent, and many cases of tubal gestation are overlooked, owing to the medical man paying too much attention to the absence of the symptom.

Now with reference to the symptoms mentioned above.

The Hæmorrhage is due to separation of the decidua which has formed in the uterus, and has nothing to do, directly, with the hæmorrhage, which comes from the site of the ovum in the tube, although it seldom occurs unless one of the disturbances of pregnancy already mentioned is present; it is never great in amount, and is very persistent, often going on for two or three weeks, with very little intermission. The patient will frequently volunteer the statement that the blood is unusual in

colour, being generally darker than ordinary menstrual loss.

The occurrence of a persistent hæmorrhagic loss in a woman of child-bearing period, if accompanied by abdominal pain, should always raise the question of extra-uterine gestation. The pain varies much in severity, and is usually intermittent, though sometimes continuous pain is complained of. In its most characteristic form it is accompanied by faintness or actual syncope and, less commonly, by vomiting. A feature in many cases, and one which is somewhat characteristic, is pain in the rectum with desire to go to stool (rectal tenesmus).

The pelvic tumour varies greatly in character; it is due mainly to effused blood and, only slightly, to the actual gestation sac or its contents. It may be found behind or on either side of the uterus, and in some cases may form a distinct abdominal tumour reaching well up towards the umbilicus. It is a somewhat ill-defined swelling, and, as felt from the vagina, may vary in consistence at different parts, owing to the varying degrees of coagulation of the blood, and, in my experience, it is almost always very tender to the touch, sometimes excessively so. In some of the worst cases there is no definite tumour, the blood being effused so quickly that there has not been time for it to clot. In these cases there is marked shock, and pallor and air hunger are prominent symptoms.

Other symptoms which may be met with are:—

Retention of urine. This occurs in cases in which a large amount of blood is slowly effused into Douglas's pouch, forming a retro-uterine hæmatocele, but it is never so marked and persistent a symptom as in cases of retroflexion of the gravid uterus. We shall refer to this point again later.

Pyrexia may be present in cases in which a large amount of blood is undergoing absorption, and does not necessarily indicate infection of the infused blood.

Diagnosis.—In the acute cases in which intra-peritoneal "flooding" occurs, the condition may simulate any acute abdominal catastrophe, such as ruptured gastric ulcer, fulminating appendicitis, twisting of the pedicle of a pedunculated tumour, etc.

In the more usual sub-acute cases there are two conditions from which a differential diagnosis is most important, as the treatment for these, if applied to a ruptured tubal gestation, would prove disastrous. These are:—

- (1) Ordinary abortion of an intra-uterine ovum.
- (2) Retroflexion of a gravid uterus.

I have seen cases of extra-uterine gestation in which one of the above has been diagnosed.

In the first case there are several points to be noted. The amount of vaginal hæmorrhage in extra-uterine gestation is never very great, and if the medical man is shown a large quantity of blood and clots he may feel sure that he is not dealing with a case of extra-uterine gestation.

The pain in uterine abortion is seldom so severe as in extra-uterine gestation, and is not attended by faintness. Finally, the diagnosis will depend mainly on a careful bimanual examination, made, if necessary, under an anæsthetic; this will reveal an extra-uterine mass in the latter case.

When an intra-uterine abortion is accompanied or followed by septic infection of the tubes, the differential diagnosis from extra-uterine gestation may be almost impossible.

In the second case of differential diagnosis from a retroflexed gravid uterus: in each there will be symptoms of pregnancy and a retro-uterine mass. In the retroflexion the pregnancy will probably have advanced farther than in the tubal gestation—viz., to the 14th week; in each case there may be reten-

tion of urine, but this is a much more constant and predominant symptom in the retroflexion than in the other. Finally, a bimanual examination must be made, and in these cases an anæsthetic is almost always required. This will enable us to determine the position of the body of the uterus—whether lying in front of the mass in Douglas's pouch, or incorporated with it.

The most difficult differential diagnosis, though by no means so important as those above mentioned, is from inflammatory affections of the Fallopian tube. Here the physical signs may be precisely similar, and unless the history helps, which it by no means always does, the differential diagnosis may be quite impossible; this is especially the case if intra-uterine pregnancy and abortion are associated with the salpingitis as mentioned above.

Other diseases simulating extra-uterine gestation are: a small ovarian cyst with twisted pedicle; appendicitis; acute intestinal obstruction, etc. In all these cases the differential diagnosis is not so important as in the first two mentioned, as active treatment by manipulations per vaginam is not likely to be attempted, and, if the symptoms are sufficiently severe, abdominal section will not be out of place in their treatment.

During the last few years I have seen some cases of plumbism, due to the taking of diachylon pills for the purpose of procuring abortion, in which the symptoms have borne a superficial resemblance to those of an extra-uterine gestation. In these cases there has been a short period of amenorrhœa, followed by some bleeding and by very severe abdominal pains; with these anæmia is frequently associated. The pulse, however, is not affected, there is no marked tenderness or rigidity of the abdomen on palpation; constipation is marked. On making a bimanual examination there is no tenderness, and no extra-uterine lump. An examination of the gums will show the typical blue line, but until one has had experience of these cases and is on the look-out for the latter sign, the true cause of the condition may easily be missed.

Treatment.—There can be little question that for almost all cases of extra-uterine gestation, under all the various circumstances we have mentioned, the treatment is *operation*. The only exception I would make is in a case of limited hæmatocele, where all signs of recent hæmorrhage have ceased, and the colour, pulse and general condition of the patient are good. In these we may try expectant treatment, and in some the clot may be completely absorbed and the patient may entirely recover; but, if this line of treatment is adopted, the patient must be under such circumstances that operative aid can be quickly obtained if signs of further bleeding set in; and increasing experience makes me less and less inclined to deal with cases on these lines.

A few questions relating to the operation remain to be considered.

As regards the route, I should unhesitatingly adopt the abdominal incision in all but a limited class of case—viz., where there is a well-marked retro-uterine hæmatocele, with symptoms suggesting septic infection of the effused blood; in these vaginal incision through the posterior fornix, with free drainage, is the operation indicated.

The question arises in cases of fulminating intra-peritoneal hæmorrhage whether it is better to operate on a patient in an almost moribund condition, or to wait for her to rally, with the risk that she may die unrelieved. Opinions differ; on the whole, I am in favour of immediate operation. If waiting is decided on, or if some delay is inevitable, then a fairly tight abdominal binder, in my opinion, may be very valuable, as it tends to drive the blood from the splanchnic veins and so prevent syncope,

in addition to any effect it may possibly have in checking the hæmorrhage by increasing the intra-abdominal pressure.

I shall not enter on the discussion as to whether, in advanced abdominal pregnancy, with a living fœtus, it is wise to operate at term or to wait for the death of the fœtus, as these cases are very rare and, in any case, no immediate decision will be required.

ORIGINAL PAPERS.

SOME UNSOLVED AND DEBATABLE PROBLEMS IN TUBERCULOSIS.

By EDWARD O. OTIS, M.D.,
Boston.

"TUBERCULOSIS has for years past given us many problems to solve" (a), says a recent writer, and it is to some of these problems upon which there exist conflicting and perhaps erroneous opinions, or for which we have, as yet, found no satisfactory solution, that I wish now to call your attention.

First I would refer to the undue emphasis placed upon the detection of physical signs in the early diagnosis propaganda. The general practitioner has now for many years been lectured, in season and out of season, upon the supreme importance of the early diagnosis of tuberculosis, and he has been unmercifully berated for his dereliction in neglecting to do this—many times justly, and sometimes, I believe, unjustly. He has become so sensitive under the censure that in my experience I find him making a diagnosis of clinical tuberculosis, not infrequently, upon indefinite physical signs, without giving due weight to the more important evidence of clinical symptoms. It seems to him more direct and scientific to base the diagnosis upon the physical findings rather than upon a painstaking investigation of the history and general symptoms—or, at least, the former occupies the foreground while the latter is relegated to the second place. The distinction between clinical active tuberculosis and local infiltration without symptoms does not seem to be always clearly comprehended—not even, perhaps, by the tuberculosis dispensary physician himself, or even the teacher. The presence of certain physical signs, definite or indefinite, with no symptoms of bacterial toxæmia, are interpreted to mean active tuberculosis, and the patient exhibiting such signs is accordingly removed from his family and employment and consigned to a sanatorium, where there is at least some risk that he may receive a new and active infection, whereas the individual was in no way ill, and probably never would have developed any active clinical tuberculosis.

"If a patient feels perfectly fit and well," says Patterson, "and his breathing capacity only is impaired, we could hardly say that he is ill with consumption. What really matters to the patient are the products of the bacteria entering into the general circulation." Drs. Gelien and Hamman (b) have, it seems to me, very justly estimated the relation between the physical signs and symptoms in making the early diagnosis when they say that "the early diagnosis of pulmonary tuberculosis is more a matter of clinical experience and judgment than of unusual skill in eliciting slight abnormalities in pulmonary physical signs." "It seems to us," they continue, "that in attempting to improve the diagnostic acumen of the general practitioner towards pulmonary tuberculosis more emphasis

should be laid upon the observation of symptoms than upon the pulmonary examination. To carry out the former is within the reach of all, while to do well the latter will be a goal unattained by most of them." Has not the tendency been to insist too strenuously upon the detection of physical signs, often slight and indefinite, to the neglect of a careful observation and interpretation of symptoms—thereby, on the one hand, causing unnecessary anxiety and the disturbance of social and business relations by instituting uncalled-for treatment; and, on the other hand, neglecting treatment because the physical examination was negative, although the symptoms of active tuberculosis were obvious?

Since writing the above a very suggestive article upon "The Responsibility for the Failure to Diagnose Tuberculosis in its Early Stages" has appeared in the Journal of the American Medical Association for April 18th, 1914, by Dr. Ralph S. Lavenson, which seems to confirm my contention that undue emphasis is placed upon the detection of physical signs in the early diagnosis of tuberculosis. Dr. Lavenson investigated fifty-four instances in which the diagnosis had been made by the general practitioner "only after from three months to as long as five years after the patient had first sought a physician presenting symptoms suggestive of, and undoubtedly referable to, a tuberculosis pulmonary infection." In 52.7 per cent. of the cases a physical examination alone was made, and depending upon the result alone of this physical examination the diagnosis was not made, although tuberculosis existed, as subsequent events proved.

Second: Marriage and tuberculosis.

Under what conditions, if any, shall a man or woman who is tuberculous (one or the other), or who has suffered from tuberculosis, marry and have children? To state the question in detail: Shall a man or a woman with arrested tuberculosis marry and have children, both as regards danger to themselves and a predisposition to tuberculosis in their offspring? Shall a man who is tuberculous, but whose disease is in a quiescent state, and who still maintains good resistance and retains his working ability, marry and have children, provided his wife is healthy? Shall a woman who has only evidence of anatomical tuberculosis with no symptoms marry and have children? Various and conflicting answers have been made to these questions. You are doubtless familiar with the oft-asserted solemn asseveration of a prominent phthisio-therapist that a tuberculous husband and wife should be taught "not to procreate a race predisposed to tuberculosis." It seems to me that this is too sweeping a statement without modifications. How do we know that the children will be predisposed to tuberculosis? The recently published experiment of Brooks (a) would appear to offer substantial proof to the contrary, reasoning from analogy. In this experiment tuberculous cows were bred to tuberculous bulls, and at birth the calves were immediately taken from their mothers and fed upon modified pasteurised milk. Of more than 200 calves thus born not one became tuberculous, and there was some evidence which seemed to indicate that animals thus born were rather more resistant to tuberculosis than animals born of non-tuberculous parents. Why should we not expect that children born under similar conditions and treated in the same way would show the same results?

Why should not a tuberculous husband, if his disease is quiescent and the balance between the infection and the resistance is evenly maintained, have children if his wife is healthy? And still more so if his disease is arrested? And yet I recall a

(a) *Transactions of the American Climatological Association*, Vol. 30, 1914.

(b) "The Subsequent History of One Thousand Patients who Received Tuberculin Tests." *Johns Hopkins Hospital Bulletin*, June, 1913, xxiv., No. 268.

(a) "An Experimental Study of Heredity in Bovine Tuberculosis." *Proc. Soc. Exper. Biol. and Med.*, 1914, xi., 50.

pathetic instance of the latter case when the wife, though healthy, refrained from bearing children for fear of the possible inherited predisposition on the side of the husband. Our American Anglo-Saxon race is so rapidly diminishing at the present time that one should be extremely cautious, it seems to me, in advising further race suicide—"the unpardonable sin for which there is no atonement," says Colonel Roosevelt—unless from very definite and clearly determined reasons. I would even go further and say that it were better to take some risks with so much to gain in the preservation of a valuable family. For example, some married people, I am sure, would be willing to shorten their own lives if by so doing they could continue their name and family. I do not suppose there is much difference of opinion as to sanctioning the marriage and child-bearing of a woman who has obtained and maintained an arrest of her disease for a number of years, or of opposing the marriage of a woman who is still actively tuberculous or who has only an apparent arrest. When the husband is actively tuberculous, but not in the advanced stage, and his wife is healthy, it seems to me it is a question for him alone to decide whether he should have children; and if the child is at once removed from the father I do not believe the predisposition bugaboo need cause anxiety.

Third: The question of rest and exercise.

After the acute symptoms have subsided—for everybody agrees that absolute rest should be maintained during the fever period—when and how much exercise, if any, should be advised? Here opinions and practice vary somewhat. Dettweiler and Pratt seem to have proved pretty conclusively that continued rest during the whole period of treatment produces excellent results. Can we show better results and fewer relapses from exercise, however carefully graduated and supervised? Again, is there any definite proof that so-called "breathing gymnastics" are, at least, of any material benefit in the "cure," and is there not an element of danger in their employment? E. Kuhn, of Berlin, has recently published a long and elaborate argument in favour of breathing exercise by means of his "Lungensaugmaske," and adduces much theoretical and experimental evidence of its value. He considers that auto-inoculation is produced not by general bodily exercise, as held by Wright and Paterson, but by the increased lung movement induced by the "Körperbewegung," and hence his conclusion is that breathing gymnastics is the essential element in the production of auto-inoculation. On the other hand, we are familiar with the not infrequently brilliant results attained by the complete immobilisation of the lung through artificial pneumothorax, and in laryngeal tuberculosis from long-continued absolute rest. It is fair, however, to state that Kuhn also advises artificial pneumothorax even in cases not far advanced or with cavities. Where mobilisation of the lung cannot be practised without rise of temperature, Paterson's method of graduated exercise has become very popular and been widely adopted; not always, however, with the same discrimination that he exercised. One must bear in mind that Paterson's cases were in the first place carefully selected for him at the Brompton Hospital before being sent to Frimley; and, further, that either Paterson himself or a trained superintendent constantly supervised the work. "Uncontrolled doses" (of exercise), says Paterson, "are in the last degree dangerous." "Treatment by means of exercise," he continues, "is not of universal application; it can only be used in the case of a patient who fulfils two rather onerous conditions. In the first place he must be afebrile and quite free from all constitutional symptoms; and, secondly, he must have attained

the position of an ordinary person in the house, by being able to remain up all day fully dressed, and to walk up and down stairs." Upon how definite a scientific basis Paterson's theory of auto-inoculation stands seems still to be somewhat uncertain. At all events it is well to remember that continued rest has produced, and does produce, excellent results, and exercise at any stage of the game has its dangers, particularly when lacking the Paterson skill in application and supervision. I recognise, however, that there are psychic conditions in the course of the treatment which may warrant a recourse to exercise even if some risk is incurred.

Fourth: Have we been over-doing, or applying without proper discrimination, the open-air exposure in the treatment of tuberculosis?

It would seem to be rank heresy even to suggest such a thing; but do we always sufficiently individualise our patients in the application of extreme open-air methods? I refer more particularly to the more northern latitudes. Take, in the first place, the far-advanced incurable cases, for even they have, not infrequently, been subjected to this treatment. What is gained by doing this and rendering their last days more wretched, when a warm ward or room—well ventilated, of course—would render their existence more comfortable? "I have seen a good many of them," said a patient in our Municipal Consumptive Hospital, to me not long ago, "put out of doors, but they all go below (to the dead house) just the same."

With regard to the earlier, so-called "curable" cases, not all, it seems to me, are suitable for the rigorous out-door system in our northern climate. Some never become accustomed to the life, and suffer genuine distress under the constant exposure to the cold, and it is, at least, a debatable question whether the excessive demands made upon the heat-producing forces of the body do not lower the resistance more than the open-air exposure raises it. They are like old people in their sluggishness of purpose. Is it not conceivable that with some individuals we would produce better results by less strenuous insistence upon out-door exposure, provided, of course, we furnish pure air in well-ventilated wards or rooms?

Or again: Are all patients equally adapted to the open-air treatment in our cold northern latitudes? Would not some do better in warmer climates, where the heat demands upon the organism are less, and where the out-door life could be enjoyed, not endured? A considerable number of persons, as we know, have a real antipathy to cold. Winter weather is to them a time of discomfort, if not of suffering. They dread cold as others do heat. They never can grow so accustomed to cold exposure as to render it anything more than a very uncomfortable experience. Even if their heat-producing centres did more or less adequately finally respond to the demands made upon them by the cold, the process would be long and painful. If, after trial, this was found to be the case, could we not obtain quicker and better results, or, at least, equally good results, under more agreeable conditions if we sent our patients, with this idiosyncrasy as regards cold, to a warmer climate for the open-air treatment, when a choice of climates was permissible from other considerations—to such a climate, for example, as that of New Mexico, Southern California, or the Pine Belt of the South? We say that "tuberculosis can be cured in any climate," and then in the same breath we say, "but a cold climate is more favourable." But is it so for every case?

Fifth, and finally: The problem of prevention in the case of a person suffering from more or less advanced tuberculosis, but who maintains indefinitely an equilibrium between his infection and his resistance, and who, in consequence, is able to

be active in the community and perform his business and social duties. He maintains his normal weight, and, for the most part, his strength; but he is constantly emitting tubercle bacilli. From business or social considerations he naturally desires to conceal his condition, and hence does not exercise all the precautions which he knows, and which we prescribe for an actively tuberculous individual. If of the well-to-do class he goes into society, he dines out, he is brought into intimate association with many people in professional or business relations. Or if of the working class, he lives with his family and is intimately associated with his fellow working men in shop or factory; he, too, that he may hold his job, desires to conceal his condition. I have in mind the case of a professional man in the higher ranks of society, who looks well, and is able to attend to his duties. From his love of music and acquaintance with musicians he goes more or less into society. He is suffering, however, from advanced tuberculosis, and his sputum always contains tubercle bacilli. Such cases must be a menace to those with whom they are brought into intimate association. They will probably never obtain an arrest, and feeling well as they do, or from other prohibitive circumstances, will not take the "cure," or have tried and abandoned it. What are we to do with them from the standpoint of prevention? We cannot compel isolation, and if it were possible, somebody would, in many cases, have to provide indefinitely for the support of the family. So long, however, as they remain in active life they desire to conceal their condition, and hence cannot, or do not, take all the necessary precautions to render themselves innocuous to others. This is one of the many problems in the prevention of tuberculosis which we have not as yet solved.

MEDICAL SCIENCE IN SHAKESPEARE'S TIME.

By A. H. MILLAR, LL.D., F.R.S.A.

Chief Librarian, Dundee.

NEARLY a quarter of a century ago—in 1892—there appeared in the columns of the *Medical Press and Circular* a very remarkable paper by John Knott, entitled "The Medical Knowledge of Shakespeare." Four years before that date (1888) Dr. Knott had contributed to the *Lancet* a leading article upon the same subject, and at that time so little was known as to the labours of other workers in the same field, that these papers were regarded as a new revelation. Nothing could be further from the purpose of the writer, for he knew that many years before his time the subject had received attention from English, American, French, and German writers. But these articles had the effect of directing attention towards a most fascinating subject, which had been suffering from temporary eclipse, but is now attracting much attention alike in the world of medicine and of literature. It would be a very pleasant task indeed to the present writer to quote numerous passages from Shakespeare's works, indicating the poet's knowledge of past medicine and premonitions of modern medical ideas; but that would require a very extensive volume. It may better serve a good purpose to indicate, however briefly, a field of research that will be attractive alike to students of literature and of medicine.

The first English writer who dealt, even in a superficial fashion, with the subject, was George Farrar, who published in 1826 a somewhat formal volume under the title:—"Observations on . . . Rates or Laws of Mortality . . . Illustrations of

the progress of Mania, Melancholia, Craziness and Demonomania, as displayed in Shakespeare's characters of Lear, Hamlet, Ophelia, and Edgar, etc." The very clumsiness of the title indicates the ponderosity of the work; yet it served to direct attention to an aspect of the work of "myriad-minded Shakespeare," which had theretofore been neglected. It is very likely that this work came under the notice of the late Sir John Charles Bucknill (1817-1897) when he became Medical Superintendent of Devon County Asylum in 1841, and thus induced him to follow the studies which resulted in his notable volume "The Psychology of Shakespeare" (1850), and his book "The Medical Knowledge of Shakespeare," issued in the following year. These works may be taken as the beginning of a scientific study of Shakespeare's medical knowledge, and they have produced a prolific crop of imitators and original investigators.

The Germans, ever devoted admirers of Shakespeare, were the first to follow up the idea. In 1865, Dr. G. Cless published at Stuttgart, a volume entitled *Medicinische Blumenlese aus Shakespeare*; which produced a volume upon a kindred topic in the same year, by Dr. C. W. Stearns of New York, under the title of "Shakespeare's Medical Knowledge." The most prolific American student of Shakespeare in the department of Medicine was Dr. A. O. Kellogg, of New York, who published his volume on "Shakespeare's Delineations of Insanity, Imbecility, and Suicide," in 1866; and contributed several remarkable articles on cognate subjects to the *American Journal of Insanity* between 1860 and 1872. The German writers who succeeded Cless were as follows:—H. R. Aubert, "Shakespeare als Mediciner," Rostock, 1873; Sigismund, "Die Medizinische Kenntniss Shakespeares," Weimar, 1881-82; and Hirschfeld, "König Lear," Danzig, 1882.

France has contributed several important works on this subject. The earliest of these were the elaborate articles by A. J. F. Briere de Boismont, entitled "Etudes psychologiques; Shakespeare, ses connaissances en alienation mentale," published in the *Annales Medico-psychologiques* of Paris, in 1868-69. To the "Revue de Deux Mondes" for 1876, E. Onimus contributed a notable paper on "La Psychologie Médicale dans les Dramas de Shakespeare." Other French writers on the subject are A. Foville, "Les Médecins dans les Drames de Shakespeare," Paris, 1885; and Bianté, "Etude médico-psychologique sur Shakespeare et ses œuvres," Toulouse, 1889.

Besides the American writers already mentioned the following are especially worthy of notice:—H. R. Bigelow, "Hamlet's Insanity," *Chicago Med. Journal*, 1873; J. Rorke, "Medical Quotations of Shakespeare," *West. Lancet*, San Francisco, 1879-80; J. P. Chesney, "Shakespeare as a Physician," St. Louis, 1884; B. R. Field, "Medical Thoughts of Shakespeare," Easton, Pa., 1884; T. J. Turner, "The Signs of Approaching Death illustrated from Shakespeare," Philadelphia, 1884; R. N. Hawley, "The Medical Lore of Shakespeare," *Med. Age*, Detroit, 1892; and O. W. Owen, "The Medicine in Shakespeare," *Physician and Surgeon*, Detroit, 1893. These names are sufficient to show that the subject has received adequate attention in the great centres of the world's civilisation.

To this country, however, naturally belongs the

honour of having directed attention to this most fascinating topic, interesting alike from a literary and a medical point of view. Hamlet has always been a favourite study with psychologists, and numerous volumes and articles have been written upon this topic, the most notable being "Hamlet, from a Psychological point of View," by W. B. Wood (London, 1870), and several contributions by Dr. Brinsley Nicholson to the Transactions of the New Shakespeare Society, from 1879 till 1882, the work of a profound student of Shakespeare. Other writers who have written articles (chiefly the *Journal of Psychological Medicine* and the *Lancet*) are R. H. Semple; F. L. S. Winslow; J. F. West; W. Wadd; L. K. H. Hackman; Sir B. W. Richardson; and John Moyes. The last-named, Dr. John Moyes (Glasgow Univ. 1886), chose as the thesis for his degree, "Medicine and its kindred Arts in the Plays of Shakespeare"; and afterwards elaborated the subject to form a most interesting volume, which was published posthumously in 1896 at Glasgow.

Hitherto the bibliography of the subject only has been mentioned, yet that is sufficient to show that an extensive literature is now available; and these notes may be useful for future investigators. Rightly to apprehend Shakespeare's relation to the medical science of his time it is needful to consider the pathological theories that were prevalent in this country during the poet's lifetime. It was a transition period. Galen, Hippocrates, and Paracelsus had still numerous and combative followers, though their dates were widely separated. This can be proved from Shakespeare's own writings: ("All's Well that ends Well," II. 3; "Merry Wives of Windsor," II. 3; III. 1; "II. Henry IV.," I. 2; "Coriolanus" II. 1). Dr. Moyes describes the time in the following striking passage:—

"Vesalius, the great anatomist, died about a year before Shakespeare's birth; Harvey announced his discovery about ten years after Shakespeare's death. In that interval great advances were made in all branches of knowledge associated with medicine. In anatomy and physiology a few names will suffice to mark the period. Fallopius was but recently dead; Eustachius still lived; Fabricius, who discovered the valves of the veins, was teaching in Padua; Serventus entombed in a theological work a description of the pulmonary circulation; Col umbus of Rome explained the relation of the pulse to the systole and diastole of the heart; and Caesalpini stood on the brink of anticipating Harvey's discovery."

While there was all this movement in the medical world of Europe, England was plunged in the depths of empiricism. By an Act of Parliament, date 1542, liberty was given to the following persons to practise medicine and surgery:—"Every person being the King's subject, having knowledge and experience of the nature of herbs, roots, and waters, or of the operation of the same, by speculation or practice, within any part of the realm of England." Shakespeare frequently ridicules this absurdity, witness his description of the Apothecary in "Romeo and Juliet" (V. 1) and of the doctor in the "Comedy or Errors" (V. 1). Dr. Caius (1510-1573) thus describes the practitioners of his day:—"Simple women, carpenters, pewterers, braziers, soap-ball sellers, apothecaries, avauinters themselves to come from Pole, Constantinople, etc." Still more

severe was Dr. Cotta, in his "Short Discovery of the unobserved dangers of ignorant and inconsiderate Practisers of Physicke in England," published in 1612. Here is one passage:—"It is a world to see what swarms abound in this kind, not only of tailors, shoemakers, weavers, midwives, cooks, and priests, but witches, conjurors, jugglers, and fortune-tellers." Verily, the practice of medicine was in a parlous condition in Shakespeare's time, as described by himself and his contemporaries.

It would be impossible in limited space to give quotations from the dramas to show how thoroughly Shakespeare was acquainted with the current theories as to diagnosis and treatment in his time; but it will be both instructive and startling for any medical student to examine Shakespeare's work to discover his knowledge of recondite subjects. But as examples of his use of the theory of Hippocrates that the liver was the great organ of blood-making and the generation of heat, take these:—

"Twelfth Night," III. 2.

Sir Toby Belch: . . For Andrew, if he were opened, and you find so much blood in his liver as will clog the foot of a flea, I'll eat the rest of the anatomy.

"Merchant of Venice," III. 2.

Bassanio: . . How many cowards, whose hearts are all as false

As stairs of sand, wear yet upon their chins
The beards of Hercules, and frowning Mars
Who, inward searched, have livers white
as milk.

The term "lily-livered," appears in "Macbeth," V. 3 and "King Lear" II. 2, and the idea is frequently used "II. Henry IV.," "Troilus and Cressida," "Antony and Cleopatra," "The Merchant of Venice," and the "Tempest."

The diseases which are, in a passing fashion, referred to by Shakespeare are these:—Ague, Fever, Leprosy, Measles, Plague and Pestilence, Rheumatism, and the Sweat. Less frequent mention is made of Apoplexy, Boneache, Colic, Consumption, Convulsions, Cramp, Dropsy, Ecstasy, Epilepsy, Gout, Green Sickness, Heartburn, Hemiplegia, Hydrophobia, Itch, Jaundice, Palsy, Sciatica, Sea-Sickness, Somnambulism, Tetter, and Visual Spectra. Passages bearing upon all these diseases could be quoted; and the remarkable fact is that Shakespeare handles them all as though he were familiar with every vagary of the sick bed. Then again, his knowledge of Therapeutics is almost weird and supra-normal, foreshadowing methods of treatment which have only recently been discovered. No doubt many of his prognostications were so vague that they could not be founded upon either carefully studied theory or practice, yet they are not the less astounding.

The student who intelligently follows out the course of Shakespearean study here outlined, will be compelled to conclude that Shakespeare was one of the cleverest physicians, most accomplished surgeons, and most learned among the toxicologists of his time, if internal evidence be of any value. But then Shakespeare has been similarly proved to be a lawyer, a theologian, a profound philosopher, a Court gallant, and an humble sailor-man! Verily, there was a whole encyclopædia of wit and wisdom contained in that colossal brain, that sympathetic heart, and that marvellous

intellect which were combined to make up that wonder of all time, whom we call Shakespeare.

THE EMPLOYMENT OF FEMALE NURSES IN THE MALE WARDS OF MENTAL HOSPITALS IN SCOTLAND.*

By GEORGE M. ROBERTSON, M.D.,
F.R.C.P. EDIN.

Physician-Superintendent of the Royal Edinburgh Asylum, Morningside, and Lecturer on Mental Diseases in the University of Edinburgh.

TEN years ago I was requested by the Secretary of the Medico-Psychological Association to open a discussion at the Annual Meeting of the Association on this subject. It was then regarded by some asylum medical officers as "the topic of the hour," largely because of certain views on administration which I had expressed and certain innovations in methods I had made at the Stirling District Asylum.

This method of caring for the insane has again come into prominence on account of the somewhat alarming position that has been created by the shortage of male attendants in asylums. No class of the community has done its duty by voluntary enlistment for the war more loyally, and the difficulties caused by the departure of attendants, and the impossibility of getting suitable men to replace them, have been relieved in many asylums by the introduction, for the first time, of female nurses on the male side. In many other institutions the advisability of taking this departure from established routine is being seriously considered. Great interest has, therefore, revived in this method of care and nursing, and I have had the unusual distinction conferred upon me of being asked for the second time by the secretary of the Association to open a discussion on it. This is now a much easier task for me than it was ten years ago, for during the interval the principles and practices then advocated have been very widely adopted in Scotland. It is not too much to say that they now form a characteristic and firmly established feature of the modern Scottish system for the care of the insane.

Many of us have now grown so accustomed to female nursing, and value it so highly, that, on contemplating the subject, the question that comes most readily to our minds is—Why were women not always employed? To others who only know the mental hospital as it now is, with its carefully designed accommodation and its comfort, its good order and discipline, its skilful and intelligent nursing staff, its prevailing atmosphere of consideration for the patients and their medical care, the question also seems a very obvious one. But the mental hospitals of to-day are not less remote from the madhouses of 125 years ago than the period we live in from the bronze age, though we inherit many archaic traditions and practices from them. The madhouses at the end of the eighteenth and the beginning of the nineteenth century were not hospitals; they were prisons for the safe custody of a dangerous class. Little wonder, then, that the methods they adopted were those of the prison, that "keepers" alone were employed on the male side and that women were rigidly excluded from it. The modern mental hospital can justly claim to be classed with other medical institutions, but if so it should fall into line with them by discarding an anachronism and by making use of women's mothering instincts and natural gifts for the nursing and care of male patients as other hospitals have done. There rests, it seems to me, a heavy responsibility upon those who now fail to do so.

* Read in London on February 17th, 1916, at the General Meeting of the Medico-Psychological Association.

(1) AUXILIARY FEMALE CARE.

The story of the introduction of women's help on the male side of asylums forms an instructive chapter in the history of the care of the insane, but it is only possible here to refer to the most important landmarks. Judging by the inertia to their employment that still exists in many quarters, although in a neighbouring country its success is an established fact, the man who first employed women in this way must have been of a very independent and original spirit. He was no less a person than Dr. Samuel Hitch, the founder of the Medico-Psychological Association. He introduced this system into the Gloucester General Lunatic Asylum in the very same year that he founded the Medico-Psychological Association, namely, 1841, and could he have survived till to-day to see the development attained by the twin offspring of his mind, he would have much reason to be proud of both of them. Dr. Hitch employed the wives of his married charge attendants to help their husbands in the male wards, and I was informed by his widow that it was because of the harsh manner in which the male patients were then treated by the attendants that he was induced to take this step. This statement is confirmed by the minutes of the asylum, which I was permitted to see, in which it is recorded that this woman's husband had charge of the refractory ward. Dr. Hitch's lead was followed by many English asylums during the next forty years.

Another step in advance was taken in 1883 by Dr. R. M. Bucke, of the London Asylum, in Canada, who employed widows of good character in the male wards. Dr. Bucke was one of the most striking personalities of the American Medico-Psychological Association, and this experiment in his hands was a complete success.

A third step was taken by Sir Thomas Clouston, who had adopted Dr. Hitch's system by placing a married couple in charge of the Male Hospital at Morningside. The husband then died, and in 1890 the widow was appointed in full charge, with the male attendants under her authority. She was permitted to engage the services of two ordinary asylum nurses to assist her, and occasionally female patients would help as well.

These three methods for the employment of women on the male side, namely, Dr. Hitch's, Dr. Bucke's, and Dr. Clouston's, illustrate what I regard as the phase of *Auxiliary Female Care*. Its defect lies in the fact that the nurses were few in number and only assisted the male attendants, and the bulk of the nursing, even in those wards in which they were employed, continued to be done by the male attendants. It would appear that no danger was apprehended to these women from the violence of the patients, but the selection of wives or widows of good character indicates that the risk of misconduct was recognised and thus guarded against.

(2) ENTIRE FEMALE NURSING.

The first step towards the system by which a group of male patients is entirely nursed by women was taken by Dr. Turnbull in the Fife and Kinross Asylum in 1896. He placed a ward containing thirty male hospital patients, by day only, entirely under the charge of female nurses. Owing to the construction of the hospital very efficient supervision was capable of being exercised over these nurses by the matron and the charge nurse of the Female Hospital. The proximity to the other male wards also enabled male help to be immediately summoned if necessary. The Scottish Commissioners in Lunacy at once realised that Dr. Turnbull's innovation constituted an important new departure and a great advance on anything that had been attempted before. Acting on the advice of Sir John Sibbald, who

thought very highly of it, a similar arrangement was soon after introduced into the Glasgow (Gartloch), Lanark and Perth District Asylums. In the year 1900, at the Stirling District Asylum, I placed a group of male patients, by night as well as by day, under the charge of female nurses, thus for the first time frankly handing over the entire care and nursing of insane male patients to women alone during the whole 24 hours.

These arrangements just described may very appropriately be called the Scottish system of Entire Female Nursing, for its special features were not only developed in the Scottish asylums, but it has been very extensively adopted by them for nearly a generation. It is a totally different thing in practice from the system I have called that of Auxiliary Female Care, in which a few women assisted the male attendants. All who have had great experience of women nurses in male wards agree in saying that they are infinitely more useful if placed in sole charge of a group, and they much prefer it themselves. The patients benefit more certainly from their ministrations, for it provides a guarantee that they must be nursed by women. Under the system of Auxiliary Female Care there is a division of labour in the ward and the nursing may be done by the men and the cleaning up and household duties by the women. The danger of misconduct, which has been already referred to, decreases as the number of nurses employed becomes greater, and is least when the care of a whole ward is handed over entirely to women. It must be remembered, too, that supervision and discipline in the asylums of the Early and Mid-Victorian period, when the system of Auxiliary Female Care was employed, were not so perfect then as they are now. What with the advent of efficient supervision and of the good class of men and women now engaged in asylum work, difficulties of this nature can be overcome and need not be feared in a modern asylum.

(3) THE HOSPITALISATION OF THE ASYLUM.

The employment of female nurses on the male side has not stopped at this stage of evolution in Scotland. Their introduction was in very large part due to the desire to make use in asylums of the very high standard of skill in nursing possessed by those who had been trained in our general hospitals. Three-quarters of a century ago, in Dr. Hitch's time, "Sarah Gamp" was in the flesh ("Martin Chuzzlewit," 1843), and there cannot have been much inducement to employ her, or others like her, on the male side for the sake of their skill in nursing. Dr. Hitch's first female nurse attended to refractory patients! If this highly skilled form of nursing be desired, then women must be employed, for unfortunately men do not receive this training in our general hospitals. Large numbers of trained hospital nurses have thus been appointed during the last twelve years to the Scottish asylums in important positions for the sake of their technical skill and training. Dr. Campbell Clark was the first to appoint a trained hospital nurse (Miss Mary Macfarlane) to the post of matron, at the Kirklands Asylum, Bothwell, in 1880. In the following year he commenced the systematic teaching and training of his asylum nurses and attendants, as was the practice in general hospitals. The idea took root, and in 1885 the Scottish Division published the Handbook for Attendants on the Insane, the most enterprising action ever taken by a division of the Association. This handbook, as is well known, has since been adopted by the Medico-Psychological Association, and has led to the granting of the certificate for proficiency in mental nursing and to the registration of certificated mental nurses. The first hospital nurse to work within the

wards among insane patients and asylum nurses was appointed by me at the Perth District Asylum in 1896. This was an important step, not only on account of its direct influence on ward work, but because it created a supply of hospital nurses who were specially trained for the duties of asylum matronship, which had not previously existed. The demand for these became so great that over three dozen of my own nurses have received such appointments in other institutions. As all hospital nurses are accustomed to attend to male patients in the general hospitals, they think it the most natural thing in the world to continue to take charge of male patients in asylums. They have gradually extended the sphere of their usefulness far beyond the limits of the hospital wards on the male side to which they were first appointed and have invaded other departments. They have introduced innumerable reforms, which have approximated the methods employed in the asylums to those in the hospitals, and amongst these the greater employment of women in the male wards is only one. The trend of events in Scotland has been such that this employment of female nurses in the male wards, when seen in its proper perspective, is found to be only a part of a much greater scheme or ideal that has flowed like a tide over the land, that of the Hospitalisation of the Asylum. It is fifteen years now since this ideal was organised into a working system at the Stirling District Asylum, and a paper describing the methods employed there, entitled "Hospital Ideals in the Care of the Insane," was published by me in the "Journal of Mental Science" in the year 1902. The details of this system go, however, beyond the scope of the present paper, and include the building of asylum hospitals, the bed treatment of the insane, the study of the physical aspects of mental disease, etc.

Time is not only a great healer, but a great judge, who decides most appeals by very convincing logic, and fifteen years is a liberal period in which to test the merits of a system of asylum management. It was said thirteen years ago by a distinguished member of our specialty that the "nursing of male insane patients by females" was "preposterous," and that to run everything in asylums on hospital lines was "a great fad." It must be hinted in palliation that this authority had not had any experience of the methods which he criticised so freely. This method of nursing is now as distinctive and as firmly established a feature of the Scottish system of care for the insane as the well-known boarding-out system. It is employed in some measure or other in all but two of the important asylums of the country, and in these the superintendents have so far failed to introduce it, not because they are opposed to it on principle, but on account of structural difficulties with regard to supervision, housing, etc. This wonderful unanimity of opinion and practice amongst Scotsmen, whose national proclivities do not tend to concord, is remarkable testimony in its favour, and points to the manifest practicability and overwhelming merits of the system. The hospitalisation of the asylum is still on the whole an ideal to be aspired to, but it too is steadily developing and gaining ground year after year. It will perhaps come as a surprise to many to know that in a fourth of the asylums in Scotland, and among them are included some of the large ones, the matron is head of the nursing staff on the male side as well as on the female. How many hospital nurses are employed as sisters or assistant matrons it is impossible to say, but it must be large, for twenty-two were lately doing duty in the military hospitals. A system such as this which has survived the test of fifteen years' experience with enhanced reputation and has become national in scope must now have some other

qualification than "preposterous," some other appellation than "a fad," applied to it by all fair-minded and reasonable men and women. The man who sees no good in it, who thinks its adoption impossible, must believe that the Scottish Board of Control and the majority of the medical superintendents in that country, in other respects with the reputation of being shrewd and level-headed, are labouring under an obsession!

Having briefly described the history of the introduction of female nursing in the male wards of asylums, I shall now refer to certain objections and difficulties.

In the first place, it is said that this work is not a suitable form of employment for women. In reply to this it may be pointed out that the work in question is actually being done by women in all but two of the Scottish asylums, and the consensus of opinion in Scotland, where experience of the system is unsurpassed, not only does not support but contradicts the objection. The personal offices that all nurses, including hospital nurses, may be called upon to perform in the nursing of adult males may be objected to, and have been objected to. Between fifty and sixty years ago, before the movement started by Florence Nightingale had been given time to effect a reformation, I have been informed by my teachers that no woman with any self-respect or regard for her reputation nursed adult males in our general hospitals. Women from every rank of society are prepared to do so now, and are held in the highest esteem if they do. Is it not, then, clear that it is not the work alone that matters, but that the spirit in which it is done, the methods that are employed and the character of the person who comes to the work, are essential elements in any judgment upon it? If, therefore, the status of hospital nursing can be so transformed in the estimation in which it is held, may not a similar change by the adoption of similar methods take place in connection with asylum nursing? If approached in the proper spirit, if performed by approved methods, and if undertaken by the right persons, this form of employment has been found in Scotland quite suitable for women.

In introducing female nurses into the male wards for the first time, the most reliable women on the staff would naturally be selected by anyone who wished the experiment to be a success. They should be experienced, and they should not be young. The working unit should not be less than four in number. It is a great advantage to place a hospital nurse with asylum experience in charge of them. The methods employed in handling the patients and in the management of the ward should be those which have been adopted in general hospitals, on account of their regard for the decencies. It is naturally found that these can be most readily adopted for those patients who are confined to bed. When the patients are dressed and going about it is advisable to employ auxiliary male care in the form of one or two trustworthy married attendants to bathe the patients and to assist in other ways if required. I have never had the least difficulty in arranging for this small amount of auxiliary male care, and I have always found convalescent and working male patients willing to help the nurses.

In the second place it has been said that the male side of an asylum is not a fit place for a woman to be in. The presence of good women always has a refining influence on male society, and whatever the conduct of male patients, in speech and in general behaviour, may be, the advent of female nurses among them, if managed with care, will effect a change for the better. The capacity of the insane for education in good habits, while not illimitable, is very extensive, and in practice it is never exhausted in our large institu-

tions. Were we not so familiar with it, their good behaviour and self-control, for example, during divine service, would astonish us every week as it does those who see it for the first time. If, therefore, it can be alleged of any asylum that its male wards are not a suitable place for women, then the sooner a reformation be effected the better for the patients there, for it is not a condition that need continue indefinitely.

It is then asked, are women who object to nurse male patients to be compelled to do this work? The answer is, of course not. There are women who object to nurse male patients, just as there are women who object to be nurses at all; but of the hundreds who have been nurses in the asylums of which I had charge, those who have objected during twenty years can be counted on the fingers of one hand. As a matter of fact, the vast majority prefer to do so, and the reason is not difficult to find. Male patients are always less troublesome and excitable than female, and women find that they receive more courtesy and readier obedience from men than from members of their own sex. They do not require to receive any extra salary to do this work once it has been started, for the women are engaged, as they are in general hospitals, simply to nurse; and it is all in the day's work whether they nurse patients of the male sex or of the female. It is very doubtful if there be any saving in expenses by the employment of women instead of men, because owing to the higher standard of hospital care aspired to, there is usually found to be a larger number of nurses required. In Scotland, any saving there may have been from this source has been more than expended on an increased night staff, which is proportionally much larger than that employed in English asylums and on hospital nurses for purposes of supervision, which is a practice that has now been largely adopted.

Lastly, it has been pointed out that many male patients, owing to their sexual proclivities, cannot be cared for by women. This is undoubtedly true, but the remedy is a simple one. Do not place them under women; let them be cared for by men. It is unthinkable that any experienced administrator would allow a simple difficulty of this kind, with an obvious remedy, to deter him from the introduction of women nurses. It may give him a little more trouble, which at present he escapes, but that is no excuse for avoiding a duty. Every day of the year, in every asylum in the country, a much more difficult and responsible task of an analogous nature is faithfully performed, that of distinguishing the patients who are suicidal from those who are not, and of making special arrangements for their care. To pick out patients whom it is undesirable to place under the care of women is, compared with this, an exceedingly simple matter.

Far from the employment of female nurses in the male wards of asylums being unsuitable in form, out of place, and objectionable to them, in the high state of organisation and development now attained by mental hospitals, whatever may have been the case in the past, it is most appropriate and a beneficent duty to the insane male patients under our care. They appear to be the last class of the helpless to benefit from the superior aptitude and skill that women show for the duties of nursing, and this privilege should no longer be denied them, as it is overdue. The reason for this superiority of female nursing rests on a solid foundation, the mothering instinct in women. It is an instinct so strong that in many cases it cannot be suppressed and must manifest itself in one form or another. There are, of course, exceptional women and exceptional men, and we have all met male attendants who have been kind

and devoted nurses. Nevertheless, nursing the sick, the infirm and the helpless, be they sane or insane, is pre-eminently woman's avocation. Sir Thomas Clouston summed up the situation tersely when he said that all his nurses longed to work in the hospital, whereas all his male attendants wished to be kept out of it, and preferred to do outdoor work, and that he never saw a man enjoy sick-nursing in the same way as many women do.

It has been remarked that only a small proportion of the male patients are in the hospital wards, but is not a great part of the work in an asylum indoor domestic duties which in a private house are also performed by women? The cleaning and decoration of the wards, the bed-making, the laundry, and repair of the clothing, the serving of the food and the social functions are all tasks which in private life usually fall to the lot of women. Can it then be doubted that they are as efficient, if not more so than men, to perform these familiar occupations in asylums.

Moreover, it must not be assumed that female nurses are only of use for the care of the sick and helpless in an asylum. One of the surprises of the system in practice has been the discovery that they can usually exercise more control over cases of mania than male attendants, and the great advantage of their management lies in this fact that it is based on persuasion, and not at all on the show of force or on compulsion. Excited patients who are ready to fight any man who comes near them will often do anything they are told by a nurse, and they will become calm if they receive a word of sympathy from her. A woman has much the same influence over an insane man, who is not actually delirious, as she has over one who is supposed to be in his sound mind, and it is absurd to assume that all feelings of chivalry and honour die in a man because he suffers from some derangement of the mind.

The proportion of women it is desirable to employ on the male side of an asylum is, according to the Scottish Board of Control, at least 25 per cent. of the total day staff on the male side and 15 per cent. of the night staff. These figures are considerably exceeded in several asylums, among which may be mentioned the Stirling District Asylum. It may be taken as a typical county asylum in the accommodation it provides, in its complete organisation, and in the modern methods it employs. It admits over 250 patients annually, and has a resident population of over 800. Dr. R. B. Campbell, its medical superintendent, has employed for the last 7½ years, as I also did for an equal period, a staff on the male side by day, of which 40 per cent. consists of women, there being three hospital nurses, including the matron. By night 27 per cent. of the staff consists of women, including the night superintendent, who is a trained hospital nurse.

It has been stated that female nurses are more suitable for asylums admitting parochial than private patients of the richer classes. That has not been my experience at Craig House. This is the department of the Royal Edinburgh Asylum for private patients, and it is quite a separate mental hospital from the West House, which provides accommodation for poorer patients. Of the staff of 32 employed on the male side by day to attend to 100 gentlemen, exactly one-half consists of nurses, including in this number the lady superintendent and three matrons, and of these three are hospital nurses. By night, six out of a staff of thirteen consist of women, including the night superintendent, who is a trained hospital nurse. These proportions vary from day to day according to requirements, and they have perhaps been swelled by the

war, but there is no difficulty in employing 40 per cent. of women by day and 25 per cent. by night in a private asylum like Craig House. Of course, there are special difficulties connected with private male patients, which are not met with in the case of parochial patients, but the employment of women in their care on the whole is equally advantageous. The opinion of the friends of patients is worth quoting. The most interested relatives of gentlemen consist chiefly of anxious females, be they mothers, wives or sisters, and nothing in my experiences gives them greater comfort than to know that the relatives whom they entrust to our care will be tended by women. Rightly or wrongly, to them it is a guarantee that no violence will be employed, and that the most skilled nursing will be available.

In conclusion, I have to state that these opinions—whatever may be their value, are founded on 20 years' experience of entire female nursing in male wards, and have been gained in four different asylums of which I have had charge during that time. I am now more convinced than ever that the mental hospital, the modern asylum, is only a hospital for the treatment of a special disease, and therefore requires to be run on hospital lines, of which the employment of women in the male wards is only one feature. Although many did not see eye to eye with me in the past, I have learned to be patient, and I have had the satisfaction of seeing these views gradually accepted and the methods I advocated adopted. The ultimate hospitalisation of the asylum is now only a question of time, and that time has been hastened by the action of many medical superintendents of the English asylums, who, owing to one of the results of the war, have introduced female nursing in the male wards of their asylums for the first time. I trust that the observations I have made may assist others in coming to a similar decision.

CLINICAL RECORDS.

NOTES ON A CASE OF PERFORATION.*

By A. D. COURTNEY, M.B.,

House Surgeon, St. Vincent's Hospital, Dublin.

THE details of this case present several unusual features, and they differ in many respects from those ordinarily given in text-books.

The patient, M. D., æt. 22, dressmaker, was admitted to St. Vincent's Hospital on February 6th, 1916, at 5.35 p.m., with the following history:—She had been suddenly awakened at four that morning by a severe pain, which she referred to the upper abdomen. She was immediately given whiskey and milk, which was at once vomited unaltered; there was no trace of blood, and she did not vomit again. The pain soon became general over the abdomen, and the patient stated that she "felt so weak" that she lay quite still in bed; she did not state that it was fear of pain prevented her from moving. Gradually this condition passed off, and she felt better, but still did not attempt to leave bed. Twice during the day she had whiskey and milk and soda, which she did not vomit, and after which she noticed no ill effects. The pain, however, remained constant, and rather more in the upper than lower abdomen. The bowels and bladder did not act between 4 a.m. and the time of arrival in hospital—namely, 5.35 p.m.

The history was not very illuminating, and were it not for the fact that she admitted on close ques-

* Read before the Medical Society, University College, Dublin, March 23, 1916.

tioning that she had been treated for "indigestion" some time previously, it would give very little indication of the nature of the trouble. Her general appearance was not more suggestive, for on looking at her one was struck with her apparent well being. There was not much evidence of distress or suffering. She lay quietly in bed, had a comparatively good aspect, had no vomiting, and the knees were not drawn up. Generally, a superficial examination would give no evidence of the grave abdominal lesion she was then suffering from. On a closer examination, however, there were unmistakable signs of intraperitoneal trouble. Her pulse-rate was from 110 to 120, but fairly good. Her temperature meantime was only slightly elevated, while her respirations were 26 and pretty regular. The abdomen was becoming gradually distended. The abdominal walls were rigid, but not markedly so, and certainly nothing like what Moynihan suggests when he says "one might almost think that a disc of metal replaced the supple muscle."

Tenderness was well marked over the upper abdomen; there was hyper-resonance, but the area of liver dulness was not completely obliterated. These signs, added to the history, brought me to the conclusion that I had a case of gastric perforation to deal with. As fourteen hours had already elapsed since the onset, I sent for Mr. Kennedy, surgeon to the hospital, without delay. I refrained from treatment of any kind, but had everything ready for operation.

At about eight o'clock Mr. Kennedy started operating. He opened the abdomen to the right of the umbilicus by an incision about four inches long. A quantity of greyish-green liquid welled up from all sides. The visceral peritoneum was everywhere congested, but there was no pus formation and but little lymph.

The perforation was first sought at the pyloric end of the stomach and then in the duodenum. Not finding it there, the incision was prolonged right up to the xiphoid cartilage. The perforation was found at the extreme cardiac end of the stomach and near the lesser curvature. It was so large that the tip of a finger could be easily inserted, and gastric contents were constantly welling through. Its high site, the distension of the intestines, and the constant welling through of fluid made it exceedingly difficult to get at the ulcer. At Mr. Kennedy's request, I, who with Dr. King was assisting him, drew down the stomach with one hand, while with the other I turned the left lobe of the liver upwards, and by this manipulation the site of perforation was made more accessible. At first an attempt was made to pass through-and-through sutures for purpose of closure. This was a complete failure, as the sutures at once cut through the tissue surrounding the ulcer, which was apparently too œdematous to hold any suture. A layer of interrupted Lembert's sutures was then passed from above the opening to well below it, and by these the whole ulcerated area was inverted. No other means than this single line of suture was used to close the perforation. Large quantities of gastric contents were found throughout the peritoneal cavity; these were got rid of by dry sponging. No douche was used, and this, I believe, had the double advantage of saving valuable time and obviating the danger of carrying infected material to any part of the peritoneum which might have escaped. Closure of the abdominal wound, with drainage, completed the operation.

Four drainage tubes with gauze wicks were left in: one through the primary incision drained the region between the stomach and the diaphragm; one was left in each loin, and one above the pubes. These latter three were inserted through stab incisions, which were made by simply cutting on to a

finger pressed from the inside against the abdominal wall.

I believe the success of the operation depended entirely on the great rapidity with which a singularly inaccessible perforation was closed; secondly by the avoidance of douching; thirdly, the completeness of drainage secured in the minimum of time.

During the course of the operation the patient received a large amount of normal saline solution administered under each breast, the needles being under the pectoral muscles, after Lane's method. She received altogether about eight pints in this manner. The idea of administering a quantity like this is so to saturate the peritoneum with fluid that absorption of toxic products is either altogether prevented or greatly diminished, and so the toxins are got rid of through the drainage tubes. When a large quantity is administered intramuscularly, there is no necessity for rectal administration for some hours afterward, and so the patient is enabled to rest and is saved a good deal of discomfort and uneasiness which the latter method involves.

The after-history of the case is one of rapid and complete recovery. The drainage tubes were removed during the first 48 hours. At first a considerable quantity of non-purulent fluid escaped through them. No pus appeared anywhere, the wound healing by first intention.

The points I would especially emphasise are:—

(1) The perforation occurred at a very unusual time, when the stomach was completely empty, and when the patient was asleep.

(2) The site of the ulcer was unusually high up at the cardiac end of the stomach.

(3) The patient drank a considerable quantity of fluid after the accident occurring without vomiting, and apparently without adding to her discomfort.

(4) The apparent well-being of the patient when first examined some thirteen hours after perforation.

(5) Lastly, the gross signs of diffuse purulent peritonitis were certainly not present to the extent one is led to believe by the accepted writers on the subject.

There are one or two points which are perhaps worth mentioning in connection with perforation, and, indeed, all acute abdominal trouble. The question of the administration of morphia before diagnosis is made is pretty well settled; but between that and the starting of operation it is not so definite. Most writers favour its administration. I have seen in at least one case very definite injury result from this, as the patient became so relieved as to refuse operation, notwithstanding all explanations, and so placed himself in grave peril.

There is also the question of continuous rectal saline, and authorities seem strong in its favour. In the few cases I have had an opportunity of watching I have always thought that its benefit must be very striking to overbalance the discomfort, anxiety, and loss of rest to a patient who is already in a dangerously weak condition. This loss of rest is present no matter how carefully and gently the administration is made.

I have to thank Mr. Kennedy for allowing me to publish these notes.

WE regret to learn that Dr. Ellis T. Evans, Medical Officer for Abersoch, Carnarvonshire, was seriously injured when riding his motor-bicycle near Pwllheli, on April 8th. He is suffering from a compound fracture of the right leg and serious injuries to his face.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

QUACKERY AND THE ETHICS OF JOURNALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In closing my last letter, whilst promising to revert to the subject, I remarked that the conduct of the great bulk of leading newspapers in regard to quackery since the issue of the Report of the Select Committee has been more than scandalous. In view of the immense power which is wielded by the newspaper Press, the maintenance of a high standard of honour amongst newspaper proprietors is evidently of vast national importance. I write on this subject with a full sense of responsibility, and if I use severe terms of condemnation it is done advisedly and with forethought. My first letter on this question appeared in your pages more than thirty years ago. I then pointed out, and I have continued since to urge the same opinion here and in other medical journals, that the attitude of the newspapers has always formed the greatest obstacle in the way of medical law reform—a problem of which the quack medicine trade forms merely a part. Writing in the *British Medical Journal* a few years ago, I declared that a great number of leading papers were virtually suborned by quackery. This statement could have been easily proved at that date. Its strict exactitude is much more easily demonstrable now. If a legally constituted tribunal were to be set up—and I am not without hope that this may some day be done—it would be impossible for either the owners, the managers, or editors of a great number of leading papers which I could name to deny on oath without the certainty of a subsequent conviction for perjury, the fact that they were knowingly, for gain, conniving at the fraudulent and cruel practices which quackery in all its forms involves.

I write now only of leading papers. I have pointed out over and over again that all papers of lower grades justify their conduct by an answer, which from the point of view of commercialism seems perfectly sufficient. These papers say that they do not feel called upon to refuse advertisements which are freely admitted to great numbers of papers standing in the front rank of journalism. It must always be borne in mind that all leading papers set themselves up as censors of social and political morality, as guardians of the welfare of the people, and defenders of the interests of their country. The proprietors engage accomplished editors as daily lay preachers of high ethical ideals. They are surely bound to live up themselves to the doctrines they thus cause constantly to be inculcated. Reference to page x. of the Report of the Select Committee will show that a sum of not less than £2,000,000 is annually spent on advertisements of patent medicines alone. The Report adds that this sum does not include the amount spent on advertising "by swindlers like Dr. —, the 'eye quacks,' the 'deaf quacks,' the cancer-curers, the consumption-curers, the electric belt makers, the curers of rupture without operation, and 'fakirs' generally."

It is thus certain that the total amount distributed among newspapers from these foul sources cannot be estimated at much less than £3,000,000 annually; and when it is considered, as I have always pointed out, that a considerable number of journals refuse to share in this income, the enormous sums gained by unscrupulous papers may be roughly estimated. I have once more quoted the

list of personal quackeries given in the Report in order to suggest the possibility of getting set up a Government inquiry into this subject. It did not lie within the province of the Committee, and the fact that they went out of their way to refer to it is most significant. If such an inquiry were instituted it would show the necessity for medical law reform on the complete scale which I have always advocated; and if I were again called as a witness on the question of newspaper advertisements I would undertake to demonstrate the entire truth of the serious allegations which I have persistently made during many years against newspapers which are looked up to with respect by at least great numbers of simple, ignorant and foolish readers.

I have already taken up enough of your space on this occasion, and I purpose to come back to the question at an early date.

I am, Sir, yours truly,

HENRY SEWILL.

THE CONSCIENTIOUS OBJECTOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If Dr. Gwillim Davies has "no sympathy with conscientious objectors," why does he try to bolster them up? There may be a "residuum of these men," such as are to be found among the Society of Friends and elsewhere, who from their early training have acquired a certain moral trend, but that does not make them orthodox and correct in their conduct as members of the social system of their country; on the contrary, it makes them selfish inasmuch as they decide to enjoy their immunity from danger at the expense of others, and it makes them unpatriotic because they refuse to help their country though urged to do so by the authorities of law and order—it makes them dangerous, too, because they set a bad example to others. And all their subterfuge is a hypothetical device which they call their "conscience," this same being not an innate knowledge of right and wrong (for no such faculty exists), but a secondary condition set up by modes of training, by emotion of fear and by ideas of self-conservatism. They are deceived in their interpretation of their own selves, on a par with those who say that the sun goes round the world because they think they can see that it does! I even grant that some of them are honest in their pusillanimous "convictions" that they believe what they think, but that is no reason for holding them to be correct in what they think, nor for allowing them to maintain their aloofness. An hereditary poacher thinks he is right in what he does; it is part of his "conscience"; but he knows that the owners of game preserves and rivers do not agree with him, and will instruct their keepers accordingly—that is another part of his consciousness—so he tries to outwit the police not because his "conscience" tells him he is doing wrong, but because he wants to save his own skin. And in the same way Dr. Davies' Hebridean cannibals had no "shame in the cruel practices which they tried to conceal"; they rather glorified in them and thought they were acting properly, but they knew that there was a vis major in the shape of Dr. Paton, who thought differently, and would probably punish them, so that it was an acquired fear of consequences which led them to concealment, not an innate knowledge of right and wrong. Let me state a case: Two children are brought up in different ways; one is educated to believe that theft, lying, deceit, hypocrisy, etc., are all wrong, and so

he grows up with a trend of mind regarding all such practices as wicked and to be avoided. The other is from childhood brought up to steal, to cheat and to deceive, so that to him the very things are right which to the other are wicked. Where is the "innate conscience" of right and wrong in these two contrasts? There is none; each has a cultivated consciousness, capable, perhaps, of modification or even of complete change in kind under a different system of environment. It is untrustworthy to quote definitions from popular dictionaries, and writers who in appealing to their readers use terms which have only colloquial significance and are not of scientific exactness, and there is perhaps no word in the English language to compare with this word "conscience," which has sheltered so much hypocrisy and false introspection.

Consciousness is the knowledge of what you *are*, not of what you *ought to be*, for you cannot be conscious of what you are *not*. A timid man is conscious of his timidity—it is himself. He may know that another is a "brave" man because he sees him do things of which he himself is afraid, but that is a different kind of consciousness, and not having it he cannot understand it. Personally, I cannot understand the consciousness of a man who can put his head into a lion's mouth or handle rattlesnakes; but if as a boy I had been trained at a zoological garden my consciousness might have been quite a different thing. The German consciousness is one of ruthlessness, of blind submission to discipline, of obedience to the law that might is right, that militarism is the correct "conscience" of the nation. Such a state of mind is the result of their purposive education. We, on the other hand, have developed a state of undiscipline and of "freedom" with the corresponding trend of consciousness that we are at liberty to do as we like, and if permitted to go on, the trend will favour the growth of "objectors." It is this state of mind which will have to be changed either by reasoning or compulsion, or by both. From what he tells us of his "sympathies," I am glad to think that Dr. Davies will assist the waverers in the consciousness of their duty—of what is the right thing, and the need of doing it.

I am, Sir, yours truly,

T. CLAYE SHAW.

Weymouth Street, W.,
April 22nd, 1916.

OBITUARY.

MR. CORNELIUS HANBURY, M.R.C.S., L.S.A.

MR. HANBURY passed away on April 11th at the ripe old age of 88, having been born on November 29th, 1827. He was the only son of Cornelius Hanbury, of Plough Court, and his second wife, Elizabeth, daughter of John Sanderson, of Avon-thorpe, and cousin of the present Lord Sanderson. Cornelius Hanbury, senior, who lived at Wellington, Somerset, during the latter years of his life, died there on March 7th, 1860. His widow lived to the remarkable age of 108 years.

Mr. Cornelius Hanbury, the son, was educated for some years under a private tutor until he became a medical student at St. Bartholomew's Hospital. In 1849 he passed the membership examination of the Royal College of Surgeons, and in the next year that of the Apothecaries' Company. In 1876 he was elected Treasurer of the Pharmaceutical Society, of which he was a Member of the Council, as well as a Governor of St. Bartholomew's Hospital.

Towards the end of the year 1849 Mr. Cornelius Hanbury first began to attend daily at the pharmacy at Plough Court, Lombard Street, then under the control of his uncle, Daniel Bell Hanbury, and his

father, Cornelius Hanbury, senior. There he became intimately associated with his cousin, Daniel Hanbury, F.R.S., whose studies in *materia medica* were to be one of the most important contributions to the science of his day. In 1868, with the retirement of Daniel Bell Hanbury and Cornelius Hanbury, senior, the two cousins became the acting partners of the firm, retaining the style of "Allen and Hanburys," first adopted in 1856, and on the retirement the subject of this memoir became sole proprietor of the business.

Mr. Cornelius Hanbury, while maintaining the same high purpose and ideals, looked far ahead and realised the possibilities of specially developing the wholesale and manufacturing lines of the firm. Years of foresighted expenditure and gradual expansion have followed. The Plough Court premises were first of all rebuilt in 1874, and at about the same time Mr. Cornelius Hanbury's only surviving son, Mr. Frederick Janson Hanbury, was taken into partnership by his father. With the changed character of the Lombard Street premises, laboratories and manufacturing premises were required and were found at Bethnal Green, and with the ever-increasing requirements these premises have again and again been enlarged and extended. In 1893 the rapidly developing business was made into a Limited Liability Company, of which Mr. Cornelius Hanbury became chairman, and his son, Mr. Frederick Hanbury, director. A little later Mr. W. Ralph Dodd, who had been many years associated with the firm, was also made a director. Coincident with Mr. Dodd's directorship extensive and commodious factory buildings were begun at Ware Mills in Hertfordshire, and there all the milk foods, the malt extracts and most of the firm's specialities are manufactured. Cod liver oil factories have also been established in Norway. There are now branch London businesses, one at Vere Street, W., of which Mr. F. W. Gamble, one of the present directors, is the head, and another at Wigmore Street, W., where the surgical instruments department is supervised by one of Mr. Frederick Janson Hanbury's sons, Mr. Reginald Janson Hanbury, M.R.C.S., L.R.C.P.Lond. (1903), now, like his brother, Mr. Frederick Capel Hanbury, a director of the company. There are branch businesses in China and at Niagara Falls, and agencies in France, Italy, Spain, India, in Australia, Africa, South America, Canada and Russia.

It is impossible in this brief notice to suggest any idea of the magnitude of the enterprise which owes its conception to Mr. Cornelius Hanbury, but it is in itself a memorial worthy of a man who combined in himself strength of purpose and far-seeing wisdom with the utmost gentleness and simplicity; a worthy type of "the fine old English gentleman." His life and example were an inspiration to all those with whom he came in contact, and the news of his death will be felt not only by those at home, but by a great number of medical friends, and of the firm's employees now serving at the front.

MR. ARTHUR E. J. BARKER, F.R.C.S.ENG. AND IREL., LONDON.

WE regret to announce the death, on active service, of Mr. A. E. J. Barker, F.R.C.S., Lieutenant-Colonel R.A.M.C., which took place on April 8th, after an attack of nephritis and acute pneumonia. Mr. Barker, who was in his 66th year, was a native of Dublin. After studying at the Royal College of Surgeons in Ireland, and at Bonn, he qualified L.R.C.S.Irel. in 1870, and L.R.C.P.Irel. in 1875. He received the F.R.C.S.Irel. in 1876 and the English Fellowship in 1880. After acting as surgeon at the City of Dublin Hospital, he later came to London, and in 1885 was appointed surgeon to University College Hospital. In 1893 he became Professor of Surgery at the hospital. When war broke out Professor Barker received the rank of Lieutenant-Colonel R.A.M.C., and became consulting surgeon to the Southern Command.

He wrote largely on surgical subjects, and was an early enthusiast in the use of spinal analgesia.

SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

The Treatment of Psoriasis with Horse Serum.—Perry (*Boston Med. and Surg. Jnl.*, February 24th, 1916), following the suggestion of Gottheil that the administration of serum to a patient diminishes the sensitiveness of the skin, has tried the effect of the administration of horse serum to patients suffering from psoriasis. Six patients with well marked psoriasis were given horse serum at weekly intervals, all other forms of treatment being omitted in order that the effect of the serum might be estimated. At first the serum was given intravenously, but as two cases of anaphylaxis occurred, in the remainder of the cases it was given subcutaneously. Dr. Perry states that he could not appreciate any beneficial results from the treatment, though the patients were unanimous in their claim that the psoriasis was much improved. Two further patients who in addition to the serum had local treatment, were markedly improved, and in one of these the eruption had entirely disappeared. Dr. Perry's experience with horse serum tends to show that results from its trial accord with those obtained by others with autogenous serum, viz., that serum whether autogenous or exogenous is of little value in psoriasis when given alone, but that when combined with local or internal treatment, for some unknown reason, it exercises a favourable influence on the disease. K.

The Percussion of Cardiac Dulness.—Shattuck (*Boston Med. and Surg. Jnl.*, March 2nd, 1916), investigates the value of the evidence of cardiac enlargement afforded by the percussion of the area of cardiac dulness. He concludes that percussion easily reveals gross abnormality in cardiac dulness to the right or to the left. It may suggest abnormalities, which must then be confirmed or disproved by other means. Percussion is especially untrustworthy for finding slight enlargement of the aortic arch, for determining the level of the apex, and for discovering hypertrophy of the left ventricle, when there is little or no dilatation. It is not worth while by ordinary percussion methods to make a silhouette outline of the heart. The attempt to make such an outline by special methods of percussion has shown, in the hands of a few, results which are good, but are more or less uncertain. K.

Mitral Stenosis in Children.—Bass (*Archives of Pediatrics*, February, 1916), records two cases of mitral stenosis in young children. The first of these was a child aged ten, who had no history of acute illness, except a mild attack of measles at three years of age. The child appeared quite normal till it reached the age of six, when it was noted to be small in size, and apparently not growing taller. Physical examination then revealed the presence of mitral stenosis. The Wassermann reaction and the Von Pirquet test were both negative. The second child was aged six years, and gave a markedly positive Wassermann reaction. Neither of the children had presented any symptoms pointing to the cardiac lesion. Bass points out that in cases of mitral stenosis in children, especially where there are no physical signs of insufficiency present, though we have no definite proof of their luetic origin, syphilis should be thought of, and a Wassermann test performed. Cardiac disease, especially valvular stenosis, exerts a considerable influence on the growth of the individual. While mitral stenosis has been observed at autopsy in infants, it is an extremely rare condition. Mitral stenosis has been observed in children over five years old in whom there was no apparent aetiological factor present. Such cases have been called congenital without there being sufficient evidence of their being so. No case of mitral stenosis has been found reported in children between the ages of infancy and five years. K.

Trench Nephritis.—Wallis (*Jnl. R.A.M.C.*, March, 1916), records the results of an elaborate investigation into the pathology and nature of the so-called trench nephritis which has been made at St. Bartholomew's Hospital for the Medical Research Committee. He comes to the following conclusions:—1. The chemical changes in the urine, both as regards the diastatic activity and the nature of the proteins present, point to the condition being a true acute nephritis. 2. The estimation of the diastatic activity may be employed to differentiate the severity of the disease, and also the prognosis. 3. The low diastase values met with in the severe cases correspond with the retention of non-protein nitrogen in the blood and cerebrospinal fluid. 4. The possible origin of the disease as the result of intestinal toxæmia or mineral poisoning is excluded. 5. There is no evidence of a recognisable bacterial infection either in the blood or urine. 6. The urine of cases of acute nephritis possesses an increased toxic action upon animals, but the nature of this agent has not been determined. 7. Although the disease has not been transmitted to animals, the experiments demonstrate that a definite illness can be induced in rabbits and monkeys, commencing eight days after the injection of the urine from acute cases, and in some with a fatal termination on the tenth day. 8. The experiments afford evidence that there is an ultra-microscopic organism present in the urine of early cases, which appears to be responsible for these ill-effects following injection of the urine into animals. 9. The investigation of scarlatinal nephritis brings out many points of interest and serves to demonstrate that we are dealing with acute inflammatory changes in the kidney in both diseases. K.

Liver Function in Normal Pregnancy.—Litzenberg (*Amer. Jnl. Obs.*, lxxiii, 2), on account of the importance given to the liver in eclampsia and toxæmias of pregnancy, undertook an investigation of the liver function, and disturbance was found in a large number of apparently normal pregnant women. The urobilinogen and the urobilin test was selected, being as near specific as any, and simple in application. Bilirubin passes from the liver and is converted in the intestines into urobilinogen, it then is absorbed and reconverted in the hepatic circulation into bilirubin, in inefficiency of the liver urobilinogen and urobilin pass into the general circulation and are found in the urine, and when found there are indicative of either abnormal distraction of red cells or liver insufficiency. Of 200 apparently normal pregnant women, 62 gave the reaction for urobilinogen or urobilin. In none of the cases was there evidence of blood dyscrasia, therefore it is assumed that there is some disturbance of liver function. Of the 62 cases giving the reaction, 11 had valvular cardiac disease and one high fever, and on account of the possibility of liver congestion from these causes were excluded. This leaves fifty-cases in which the interference with liver function could only be accounted for by the pregnancy. Congestion of the liver due to the enlarging uterus is suggested as a possible cause. This is favoured by the fact that the reaction was found with increasing frequency as the end of term approached. It is also suggested that there may be a liver of pregnancy as well as a kidney of pregnancy. F.

Compensatory Menstruation.—Condit (*Amer. Jnl. Obs.*, lxxiii, 2), reports a case of a woman from whom he removed the uterus and all the annexæ, but at the next menstrual period pre-menstrual symptoms of a normal character developed and hæmorrhage into a small nævus occurred, this continuing to occur regularly every 28 to 34 days, for twenty-one months, the nævus gradually increasing in size from monthly

increase with partial regression, until it formed a large tumour under the skin with the original nœvus like a nipple. It then ruptured and external bleeding developed at a menstrual period. The tumour was removed, but at the next period swelling and extravasation of blood developed into the left mammary gland, and continued for one year regularly and then became less frequent and regular and disappeared after two years and one month. Six years after operation ecchymosis of the extensor surface of both legs occurred and recurred at irregular intervals for several months. The last attack was on the posterior surface of the leg, from the gluteal region to the ankle. It is supposed that some ovarian tissue persisted, and that the phenomena showed themselves in the skin or derivatives of the skin, and in those parts offering least resistance to the vascular changes. The phenomenon of menstruation is briefly considered, and the various theories from the literature cited with zoological analogies. The writer concludes that menstrual abnormalities or irregularities are due to blood pressure changes in the individual, together with some atrophic or pathological changes in parts where the hæmorrhage manifests itself. The demonstrations in the case reported being due to failure in the individual physical economy to adapt itself to the change brought about in the blood pressure by removal of the parts previously acting as a safety valve. F.

Neuritis in Pregnancy.—McCarty (*Amer. Jnl. Obs.*, lxxiii, 2) says that peripheral neuritis occurring during pregnancy may develop before or after labour, and may be local, involving a single nerve or multiple. It varies from a single disturbance of sensibility to complete anaesthesia, paralysis, and muscular atrophy. The less marked degrees characterise the cases occurring during the early months of pregnancy. The puerperal cases appear to be chiefly due to involvement or damage of local nerves by local conditions, such as pelvic cellulitis or other direct pressure. During gestation the frequent association with other manifestations of toxæmia points to a probable toxic origin, and this may often be due to a metabolic disturbance. Multiple neuritis appears usually in the middle or later months of pregnancy, often tingling in the arms or legs, tenderness along the course of the nerve, and may extend to anaesthesia and muscular loss of power, and often persists until after delivery. The prognosis is favourable. F.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons.

FLEET SURGEON P. W. BASSETT-SMITH, of the Royal Naval Hospital, Chatham, and Mr. J. F. Colyer, of the Royal Dental Hospital, London, have been elected Fellows of the Royal College of Surgeons. Mr. W. B. Littlejohn, of Oxford University and St. Bartholomew's Hospital, having passed the required examinations, has been admitted a member of the College, and Mr. G. F. H. Bloom, of Guy's Hospital, a licentiate in dental surgery.

Sunday Work on Munitions.

In the House of Commons on April 17th, Mr. Pratt asked the Minister of Munitions to state what steps had been taken to carry out the recommendation of the Health of Munition Workers' Committee in favour of a weekly period of rest for all munition workers; and to what extent it had been found possible to reduce Sunday labour.

Dr. Addison, who replied, said: My right hon. friend is keenly alive to the importance of securing to munition workers an unbroken rest period of not less than 24 hours weekly. A circular recommending that this weekly rest period (preferably on Sundays) should be secured to all workers was sent out on December 7th, 1915, to all controlled establishments. This was followed by an inquiry addressed to each establishment, and a Committee was subsequently appointed to deal systematically with the subject. There are many practical difficulties in the way of

securing the entire abolition of Sunday labour, but substantial progress has been made, and out of the 2,383 firms, from whom particulars have been obtained, 1,440 are now employing no Sunday labour. Of those firms who work on Sundays, 60 have notified the Department that all workers are provided with a rest period of at least 24 hours each week. Constant and pressing attention is being given to the matter, and it is hoped that the number of firms employing no Sunday labour will shortly be largely increased.

A Neutral Doctor on Wittenberg.

A NEUTRAL'S confirmation of the barbarous conduct of the German authorities during the typhus outbreak at the prison camp at Wittenberg is contained in an article in the American monthly publication the *Military Surgeon*. The writer, Dr. B. W. Caldwell, of the American Red Cross, made a thorough inspection of several of the camps in Germany, including Wittenberg, in November last, and he says:—

Typhus exanthematicus made its appearance in two or three of the camps, causing frightful morbidity and mortality in one. This regrettable occurrence was due to the inhumanity of the prison commandant, who, when typhus broke out in the barracks, among the Russian prisoners, insisted upon the English, French, and other prisoners occupying the same barracks, with the infected Russians, until some 800 of the prisoners became infected with the disease, and about 300 of them died. This epidemic when the commandant was shorn of a part of his authority and effective measures were established within the camp, was soon controlled.

Medical Men and War Service.

In the House of Commons on April 12th, Mr. Tennant, replying to Sir J. Lonsdale, stated that medical men between the ages of forty-five and fifty-five were being employed as commissioned officers for general service in the United Kingdom. Doctors over fifty-five might offer their services for local employment to the General Officer Commanding-in-Chief of the Command in which they were living, or in which they desired to do duty with troops. In other words, the policy should be that the medical men of more advanced years rendered the country the better service by undertaking the care of the civil population, and thus setting free those of military age who were physically fit for duty at home or abroad.

The Child's Food.

At a meeting of the National Clean Milk Society, held on April 12th, Lord Plunket suggested that firms supplying clean milk should supply it in attractive bottles in Greek designs, instead of the present ugly vessels. Ladies might turn their attention to designing covers such as those used for bringing champagne bottles to table, and thus give an artistic pleasure to a utilitarian beverage.

Sir Thomas Barlow spoke on the failure of the various tests to produce a good imitation of mother's milk during the past 25 years, the greater number of infants' foods being deficient in fats. There should be as little tinkering as possible with fluids intended for children. As the sterilisation of milk and the use of dried foods spread in upper class nurseries a new form of malnutrition or infantile scurvy, similar to that from which sailors on long sea voyages without fresh food used to suffer, was seen. A speedy recovery was found on giving fresh milk, a little orange juice, and a little gravy. Milk should be pure, even if it was sometimes diluted or modified, but it must not be tinkered with. There must be cleanliness of the byre, the cow, the cow's food, the vessels from which it drank, and the hands of the milker.

Soldiers and Tuberculosis.

In the House of Commons on April 10th, Mr. Tennant, replying to Major Astor, said it was considered that a man suffering from pulmonary tuberculosis was unfit to serve as a soldier. It was essential that these cases should be specially treated in a sanatorium at as early a date as possible. With this object, in the

man's own interests, arrangements had been made with the National Health Insurance Commissioners and the Local Government Board that soldiers found to be suffering from tubercle of the lung should be discharged the service at once and admitted to a sanatorium.

Major Astor: Is it not possible to alter the regulations and put this disease on all tours with other diseases, so as to give soldiers suitable treatment before they are discharged from the Army?

Mr. Tennant: I do not say it would not be possible; I think it might be possible; but whether it would be desirable or not is another matter. I will engage to have the matter further investigated.

Major Astor: Is it not the fact that there is the greatest difficulty in getting soldiers to go into a sanatorium when they will have no separation allowance, and that it is this point that should be considered?

Mr. Tennant: If they are discharged from the Army, of course, they get no separation allowance.

Major Astor: Ought they not to get treatment before they are discharged.

Mr. Tennant replied that he would undertake to have the matter looked into.

Cambridge University Finance.

Cambridge University Accounts for 1915 show ordinary receipts in the Chest amounting to £33,700, as compared with £46,800 in 1914. The expenditure amounted to £38,100 (as against £48,600 in 1914). Against this deficiency £7,000 has been transferred from the Common University Fund (contributions from colleges) and £1,350 from trust funds under the Emergency Powers Act of 1915. The balance to be carried forward is thus increased by £3,900.

The most noteworthy features in the accounts are the loss of income derived from fees and the reductions in expenditure under almost every head, which have gone far towards meeting the loss. The University now holds upwards of £90,000 War Stock and £12,000 in Treasury Bills.

The British Steel Helmet.

In the House of Commons on April 19th, Dr. Addison, replying to Mr. P. A. Harris, said the service steel helmet weighed 32 oz. Improved internal fittings were now being made which would improve the ventilation and render the helmet more comfortable. The helmet had given great satisfaction, and had saved many casualties. It was not proposed to alter the pattern. He knew of no helmet weighing 16 oz. that possessed equal resisting properties.

Mr. Joynton-Hicks: Is the hon. gentleman aware that the French helmet is much more efficient, and weighs 8 oz. less?

Dr. Addison said that was entirely incorrect.

Italian Army Doctors.

The Italian Cabinet met on April 18th to discuss a number of important measures, one being the supply of doctors and surgeons for military purposes.

According to the *Messaggero*, it was decided that the age limit should be raised for the medical services, and that doctors and surgeons up to the age of 45 who have performed military service should now be taken. It was further resolved that medical men of the 1876 class who had been rejected for service owing to illness should be called for further examination.

Sheffield Royal Infirmary.

The annual meeting of the Board of Governors of the Sheffield Royal Infirmary was held on April 12th.

Mr. H. H. Bedford (Chairman of the Weekly Board) expressed the thanks of the Board to the whole of the staff of the institution for their services, especially mentioning the honorary medical staff and the lady doctors. The work of the Royal Infirmary, he said, had been particularly heavy. In the out-patient department, where they expected that in consequence of the Insurance Act there would have been a falling off, they had had a big increase. So many people in Sheffield were engaged on munitions of war, and many of them not much accustomed to dealing with machin-

ery and tools, that accidents had increased very considerably. Accident cases dealt with numbered no fewer than 21,236. The staff had also attended to exactly 1,000 wounded soldiers in addition to their ordinary work. The finances were a constant source of anxiety, but it was with very great feelings of gratitude that they had managed to "live" within their income, which was not a thing an institution like theirs could always do. This was due in great measure to the generosity of some of the big works. The workmen's and the Hospital Saturday and Sunday collections were all up, while Alexandra Rose Day helped them to the extent of £877. The expenditure must continue to increase in consequence of the war. In milk alone the expenditure had increased by £500 a year. He alluded to the depletion in the medical, nursing and general staff of the institution on account of the war, and gave instances of the services that were being rendered to the country by the various members of the staff.

Health Visitors.

DR. E. C. THOMAS, medical officer, has informed the Carmarthenshire Public Health Committee that the cost of an ideal scheme to combat infant mortality would be prohibitive at present, for it would require a staff of at least 10 nurses at a salary of £100 each per annum. The question was an important one, for if the mortality continued at the same rate as that recently reported during the first week after birth for a period of 42 weeks, all the children born would have died. He attributed the majority of the deaths to neglect and ignorance.

Sir A. R. Simpson's Bequest.

SIR ALEXANDER R. SIMPSON has left the museum formed by his uncle, the late Sir James Young Simpson, the discoverer of chloroform as an anæsthetic, to the University of Edinburgh. He had previously given his uncle's and his own libraries to the Royal College of Physicians, Edinburgh.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations were granted the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery, and midwifery:—E. V. Beaumont, M. J. Byrnes, and E. N. Glover.

National University.—University College, Dublin.

The Examiners have made the following recommendations to the Senate:—

SPRING MEDICAL EXAMINATIONS.

Second University Examination in Medicine.—Honours:—First Class: Heffernan, Michael. Second Class: O'Brien, Michael F., M.A. Pass (in addition to the above): Carr, Connell; Cooney, Mark A.; Doyle, Wm. F.; Garry, Patrick T.; Healy, John J.; Macabe, John J.; M'Mahon, John R.; M'Nulty, Jas. P.; M'Nulty, Madeline A.; M'Grath, Daniel P., B.A.

Third University Examination in Medicine.—First Class Honours: Chanco, Alice B., B.A. Second Class Honours: M'Carvill, Patrick; Hickey, Richard; Macnamara, Donagh W. Pass (in addition to the above): Briscoe, Abraham; Byrne, Patrick J.; Clarke, Mary C.; Conlin, Patrick J.; Irvine, Maggie; Kelly, Eugene F.; Lawlor, Solomon; Maguire, John; Mullin, John J. A.; O'Dowd, Patrick J.; Rowan, Joseph H.; Shiel, Wm. F.; Swan, Harold J.

M.B., B.Ch., B.A.O., Degrees Examination.—Honours:—Second Class: O'Connor, John J. A.; Moran, John P.; O'Sullivan, Michael; Ryan, Andrew; Bouchier-Hayes, Eileen M. E. Pass (in addition to the above): Blake, Leo; Burke, Thomas J.; Carroll, James C.; Clements, Michael A.; Coyne, Edward P.; Curtin, Jeremiah; Doherty, Annie; Dooley, Annie; Dwan John; Hughes, Daniel; Morris, Wm. M.; Murphy, Philip; O'Connell, Patrick; O'Malley, David V.; Owens, Henry E.; Pollard, John. Exempted from further examination in the subjects set after their names: Lagan, B., Medicine; Murphy, Patrick D., Surgery, Ophthalmology, and Midwifery; O'Brien, John J.; Ophthalmology and Midwifery; O'Mahoney, Thomas, Surgery and Midwifery; Walsh, Edward, Surgery, Ophthalmology, and Midwifery.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

WOMEN'S WORKING HOURS.

IT is stated that hours for women and girls on munition work are not to exceed sixty a week.

PRICE OF COD-LIVER OIL.

THE price of cod-liver oil is now at least eleven times the pre-war figure, and is advancing almost every week.

GIFT OF LAND TO HOSPITAL.

AN anonymous donor has made the Royal Free Hospital, Gray's Inn Road, a gift of nearly an acre of land adjoining the hospital, which would be available for an extension of the buildings particularly needed in connection with maternity work and infant welfare.

THE FALLING BIRTH-RATE.

DR. A. E. HARRIS, Islington's Medical Officer of Health, reports that for the first quarter of this year the birth-rate, 21.45 per 1,000 was the lowest in the borough in any corresponding quarter.

INFANTILE MORTALITY.

MR. LONG gives the following figures as to the deaths of children under one year in England and Wales:—

Six months ended March 31, 1913	47,274
Six months ended March 31, 1914	48,965
Six months ended March 31, 1915	50,219
Six months ended March 31, 1916	41,971

"SYNTHETIC" CAVIARE!

OWING to the sale in Berlin of coloured herrings' roes as "genuine German caviare," the *Deutsche Tageszeitung* warns the public against the counterfeit goods, reminding it that "not even our brilliantly resourceful German chemists can make synthetic caviare."

CROWDED LONDON.

BOROUGH Council returns show that London is more crowded than ever before. Islington, which once lamented the flight of residents to other suburbs, now declares the number of empty houses to be continually decreasing.

THE CLOGS OF WAR.

OWING to the high price of children's boots, the wearing of clogs by school children is becoming quite common in South London, and one bootmaker in Walworth Road has devoted the whole of his window to a display of them.

GROWTH OF NATIONAL INCOME.

MR. MCKENNA, in a Parliamentary answer, says that the gross income brought under the review for income-tax of the Commissioners of Inland Revenue for the years mentioned was as follows:—

Year.	Amount.
1904-05	£912,129,680
1912-13	1,111,456,413
1913-14	1,167,184,229
1914-15 (estimated)	1,240,000,000
1915-16 (estimated)	1,380,000,000

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 26TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes):—5.30 p.m.: Prof. A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

FRIDAY, APRIL 28TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of Lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes):—5.30 p.m.: Prof. A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

MONDAY, MAY 1ST.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.—8.30 p.m.): The Annual Oration will be delivered

by Sir St. Clair Thomson, M.D., F.R.C.P., on "Shakespeare and Medicine." There will be an exhibition of portraits, books, and other items of Shakespearian interest. The exhibition will remain open for the next three days.

TUESDAY, MAY 2ND.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY, SUBSECTION OF ORTHOPEDICS) (1 Wimpole Street, W.).—5 p.m.: Annual General Meeting: Election of Officers and Council for Session 1916-1917.

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Annual General Meeting: Election of Officers and Council for Session 1916-1917. Communications: Dr. Andrewes. Dr. J. A. Murray: A Transplantable Tumour of the Guinea-pig. Dr. B. H. Spilsbury: Specimen Illustrating Toxic Hepatitis. Mr. Shattock: (1) Some Points in Connection with the Vermiform Appendix; (2) Some Specimens Illustrating Gun-shot.

Vacancies.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Manchester Northern Hospital for Women and Children, Park Place Cheetham Hill Road, Manchester.—Lady House Surgeon., Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38 Barton Arcade, Manchester.

Royal Berkshire Hospital.—House Surgeon. Salary £250 a year, with apartments, board and washing. Applications to Herman Burney, Secretary.

The Royal Infirmary, Sheffield.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.

Victoria Hospital, Burnley.—Female House Surgeon. Salary £160 per annum, with residence, board and washing. Applications to F. A. Hargeaves, 7 Grimshaw Street, Burnley.

St. Bartholomew's Hospital, Rochester, Kent.—Senior Resident House Surgeon. Salary £300 per annum. Applications to Charles Speyer, Secretary.

Winsley Sanatorium, near Bath.—Assistant Resident Medical Officer. Salary £250 per annum, with board, residence and laundry. Applications to Frederick Jones, Secretary.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence and washing. Applications to the Hon. Secretary, Infirmary, Bury, Lancs.

Putney Hospital (Chester, Bequest), Lower Common, Putney, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board and laundry. Applications to the Hon. Secretary, at 198 Upper Richmond Road, Putney, S.W.

Appointments.

ERSKINE, W. J. A., M.D. Edin., Medical Superintendent Isle of Wight Asylum, Newport.

FARRER, R. T., M.R.C.S., L.S.A., Certifying Factory Surgeon for the Brighouse District, co. Yorks.

PALMER, A. S. M., M.D. Cantab., Medical Officer of the Convalescent Home, Worthing, of the Kingston (Surrey) Union.

SMITH, J. H., M.B., C.M. Edin., Medical Officer of the Institutions and First District of Stockport Union.

Births.

FULLER.—On April 17th, at Milnthorpe, Westmorland, the wife of W. A. Fuller M.R.C.S., L.R.C.P., of a son.

WARD.—On April 17th, at Withycombe Lodge, Torquay Road, Paignton, to Dr. and Mrs. Ward—a daughter.

Marriages.

DARLINGTON—BACHELOR.—On April 20th, at Grange Road Presbyterian Church, Birkenhead, Captain G. Hellyar Darlington, R.A.M.C., son of Mr. and Mrs. J. Darlington, of Liverpool, to Ida M., elder daughter of Captain J. W. Batchelor (Liverpool Salvage Association), and the late Mrs. Batchelor, of Birkenhead.

DAVIES—EDMUNDS.—On April 18th, at Holy Trinity Church, Southport, Dr. L. E. Davies, son of the late William Davies, of Southport L.R.C.P., L.R.C.S. Edin., to Mary Constance, daughter of the late Richard Edmunds, J.P., M.R.C.S., L.R.C.P., of Pontnewydd, near Newport, Mon.

DRURY—BROWNSWORD.—On April 19th, at St. Bartholomew-the-Great, London, Alan Nigel Drury, Lieut., R.A.M.C., youngest son of Mr. H. C. Drury, M.V.O., and Mrs. Drury, of Northwood, Middlesex, to Daphne Marguerite, elder daughter of Mr. H. A. Brownsword and Mrs. Brownsword, of Rollesby Hall, Norfolk.

Deaths.

ELWIN.—On April 24th, at 23, Alwyne Road, Canonbury, Charles Jeken Elwin, M.R.C.S., for 37 years at 6 City Road E.C., in his 82nd year.

STEVENS.—On April 13th, at Southampton, after a long and painful illness, George Stevens, F.R.F.P.S.Glas., late of Norton, Suffolk, aged 75 years.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MAY 3, 1916.

No. 18.

AT THE PERIPHERY.

"*Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer.*"—BEAUMARCHAIS.

THE *Edinburgh Review*, which in spite of distinguished competition remains the greatest of the Quarterlies, contains in the current number two articles which hold a very particular interest for medical men. The first is on "The Psychology of the English," by Mr. Havelock Ellis, a writer who has contributed a great deal to our knowledge on some important subjects of which it would be a good thing if everyone knew more. The present article is, however, quite free from the reproach which has been levelled at some of his other writings by the prudes and the hypocrites, more eager for external righteousness than for inward grace, who are said by the French to constitute the majority of the inhabitants of these islands. "The Psychology of the English" is intensely interesting, and no medical man with a broad outlook should miss reading it. The other article is on "The Control of Venereal Disease": I shall return to it presently.

THE *Edinburgh Review* was started in 1802 by a few men, of whom at least three—Sydney Smith, Brougham, and Jeffrey—lived to be famous. The inception of the great quarterly was thus described by the first-named, who was probably the wittiest man that this country has produced: "I proposed that we should set up a review. This was acceded to with acclamation. I was appointed Editor, and remained long enough in Edinburgh to edit the first number of the *Review*. The motto I proposed for the *Review* was 'Tenui Musam, meditamur avena' (We cultivate literature on a little oatmeal). But this was too near the truth to be admitted; so we took our present grave motto from Publius Syrus, of whom none of us had, I am sure, read a single line." The motto referred to is "Judex damnatur cum nocens absolvitur"—which, being translated, means "The acquittal of a criminal displays the incapacity of the judge." Macaulay, most of whose Essays originally appeared in the *Edinburgh* thoroughly upheld the principle of this motto.

SOME of the stories concerning Sydney Smith and his *Review* colleagues are immensely funny. Of Francis Horner, one of these colleagues, he said that "he had the Ten Commandments written on his face, and looked so virtuous that he might commit any crime with impunity." At a much later period, seeing Brougham's carriage with "B." surmounted by a coronet on the panel, Sydney Smith said, "There goes a carriage with a B. outside and a wasp inside." One of the most amusing stories of the *Edinburgh* days is the following: "Leslie, the Scottish philosopher, had called upon Jeffrey just as the latter was going out riding, to ask him to explain some point concerning the North Pole. Jeffrey, who was in a hurry, exclaimed as he rode off: 'Oh! damn the North Pole!' This hurt Leslie's feelings, and he complained of it to Sydney Smith, who entered gravely into the matter, and told him in confidence that he himself had once heard Jeffrey speak disrespectfully of the Equator!"

FOLLOWING a tradition which used to be *de rigueur* in English magazine articles, the name of the contributor who deals with "The Control of Venereal Disease" is withheld. That does not prevent me from offering him my humble compliments upon the thoroughness and excellence of his work. After a brief but lucid preamble addressed to the lay reader upon some points in connection with venereal diseases which are alphabetical to all medical men, the writer inquires into the best means for preventing and ultimately stamping out these dread scourges, even as typhus, typhoid and small-pox have been practically stamped out. The result is a well-reasoned, clearly written article, full of tact and discretion, revealing the wide outlook of a far-seeing orderly mind. It is an article to which every medical man should give very careful attention, and, in so far as he is able, he should see to it that it is well read by the laity. It might very suitably be issued in pamphlet form for distribution by doctors among their patients.

An Obstacle to Progress. "ONE serious impediment to successful treatment," says the writer, "is the resort of patients to unqualified practitioners such as chemists and druggists and medical herbalists . . .

As regards resort to unqualified persons and the employment of quack remedies, much detailed evidence is given in a Parliamentary Paper issued in 1910 (Cd. 5422). It is there stated that in many of the great towns the treatment of venereal diseases is largely in the hands of unqualified persons. There can be no doubt as to the resulting mischief . . . Dr. Johnstone, a medical inspector of the Local Government Board who made a valuable report on venereal diseases to that Board just before the work of the recent commission began (Cd. 7029, 1913), stated that medical men in various towns informed him that they were rarely consulted until the patient had spent some weeks in the hands of a herbalist or chemist, or in trying some advertised cure." This is common knowledge to every medical man who is acquainted with the conditions of practice, especially in the smaller towns.

In spite of this, and indeed of much more which could be said on the subject, "the Royal Commission do not propose any direct action in regard to unqualified practice. Doubtless they have refrained from doing so because of the thorny character of the problem, and the apparent impracticability of securing, so far in advance of public opinion, the legislation which would be required to secure practical reform. They content themselves with strongly endorsing the recommendations of the Select Committee on Patent Medicines that all advertisements of remedies for venereal diseases should be prohibited."

Want of Training. A CURIOUS point which the Report of the Commission seems to emphasise is the alleged need for additional medical training in relation to venereal diseases. It is probably true that men trained more than twenty years ago have very antiquated notions about the diagnosis, prognosis and treatment of these diseases, and it would certainly be safe to admit that the gravity of gonorrhœa is not sufficiently recognised even by those who have been qualified more than ten years; but I think it is an exaggeration to say that the man whose qualification bears a date as recent, say, as 1910, is in any way behindhand in the knowledge necessary to the prompt diagnosis and adequate treatment of either of these diseases; and the more recent his diploma, the better equipped in such knowledge is a man likely to be. The teaching of the schools is certainly thoroughly up to date, and the attitude of the ordinary medical student is usually such as to cause him to assimilate such teaching with something akin to avidity.

A Quotation. THE Report of the Commission and its recommendations are very well and soundly criticised, in the real sense of the word, by the writer of this admirable article. What he has to say on the questions of notification (p. 369) and

prophylaxis (p. 371) are specially worthy of attention. I have already drawn freely on the text, but I cannot refrain from adding this further quotation as a sample of the spirit in which the matter is dealt with. "Even were it true that all venereal disease is due to immoral conduct, that none is inherited, none innocently acquired, it would still be difficult to understand how any thoughtful and humane person could deliberately prefer that mankind should continue to suffer from these terrible diseases rather than that a sinner should be speedily cured. The experience of the world proves conclusively that in no country has the dread of venereal disease ever prevented the existence of irregular sexual relationships. Few people who are able to look facts in the face can hold the belief that the world will ever reach a stage when the rules of monogamy are strictly and universally observed. But if that stage should ever be reached, it is certain that the change will be due to moral causes, not to a materialistic fear of specific diseases. Do the people who refuse to "condone vice" really think that it is justifiable to allow the race to be saturated with syphilis while waiting for an epoch of universal purity?"

In the *Contemporary Review* for April Sir Thomas Barlow deals "Contemporary" briefly, but effectively, with the "Review." Report of the Royal Commission.

He tells us that the Committee of the National Council for Combating Venereal Disease (Kingsway House), of which he is chairman, "was initiated shortly after the appointment of the Royal Commission, with a view to endeavouring to carry forward the recommendations of the Commission when they were issued, and to rouse the public conscience as to their urgency. Hitherto its efforts during the war have been specially directed to giving voluntary warning lectures by medical men to large bodies of soldiers, with the sanction of the War Office, and also to courses of lectures addressed to social workers. Whilst continuing this necessary work, it is hoped that an educational propaganda may now be initiated, specially addressed to municipal bodies, but appealing to all men and women of goodwill who desire to grapple with one of the most potent causes of national degeneracy." In this admirable work the Council can count upon the goodwill and, as far as is possible, the active co-operation of every member of the profession.

A New Gospel. IN the same, the April, number of the *Contemporary* there is an article by Mrs. Dew, entitled "Why Need We Be Poisoned?" which is deserving of more than a cursory notice. I shall hope to return to it later. It sets forth something in the nature of a new gospel on the already well-worn subject of dietetics. The high priest is Mr. William Aird, who seems in one sense at any rate to be a phenomenon, for he is completely disinterested. The gospel has the merits of extreme simplicity in exposition and of extreme cheapness in practice. "Live on foods that need no cooking—fruits, vegetables, nuts—until you feel

fit." Mrs. Dew closes her article, which amounts in reality to the testimony of a beneficiary, with the following essentially human and engagingly disarming words: "This appeal is not made to the shining ones of the earth, or to those who walk humbly in their footsteps. It is made to the weak, the self-indulgent, the greedy, the gluttonous, and the selfish, by 'One of Themselves.'"

I AM sometimes asked what the British Medical Association has done to me that I should continue to hold it up to obloquy. The reply is that the matter is not a personal one. As

The B.M.A.

an individual I have nothing against the Association. It has never done me any harm; though some years ago, fearing its proved capacity for bungling and bad faith, I deemed it wise, by resigning my membership, to deprive it of any power to affect me adversely. My case against the Association rests purely on public grounds. In the un instructed public eye, the British Medical Association represents the medical profession, and it is right that this eye should, if possible, be educated to see clearly in this matter; it must be taught to realise that the British Medical Association no more represents the profession than Upper Tooting represents the Empire. Of its unfortunate want of tact, taste and temper I have already given several examples in connection with the recruiting of the profession for war purposes; of its behaviour in connection with the Insurance Act I could say a great deal, and much that I could say (and intend on some future occasion to say) on this subject, would surprise even those who already hold it in small esteem. My present purpose is to call attention to the manner in which it "represents" the interests of the profession in a matter of no inconsiderable importance.

ON page 565 of the *British Medical Journal* of April 15th, 1916, under the heading "Notification Fees," there appears an account of the consideration in Committee of the House of Commons of the Local Government (Emergency Provisions) Bill, which included a discussion on the fees payable to medical men for notifying the diseases which under statute are compulsorily notifiable. These fees, as is well known, have hitherto been 2s. 6d. per notification, a sum which the authorities now proposed to reduce to one shilling. On grounds which must be perfectly obvious to any thinking member of the profession, this proposed reduction was resisted. What does the British Medical Association do? Does it support the resistance and object *in toto* to any reduction in the already meagre scale of fees for work which, while requiring skill, time and judgment on the part of the doctor, is of enormous value to the community? Let us see.

I QUOTE from its own report "The B.M.A.'s Part. A deputation from the British Medical Association admitted that one shilling would be sufficient for notifying measles, but urged that 2s. 6d. should be retained for all other diseases." To this

the authorities promptly replied that "they could not differentiate between different diseases, and that if 1s. was sufficient for the notification of measles, then 1s. was sufficient for drawing up a simple form with regard to other diseases notified." Now this retort, thus kindly put into the official mouth by the British Medical Association, is logically and scientifically unanswerable. "If you can do measles for 1s., why not scarlet fever? And if scarlet fever, why not all the rest?" To this thrust there is no possible riposte; and the weapon for the thrust is genially placed in the official hand by the British Medical Association, which claims to watch over and represent the interests of the general practitioner! Could there anywhere be found a better instance of the pettifogging, suburban spirit, the meanness of outlook, the paucity of imagination, and the dunderheaded diplomatic dabbling so characteristic of the Association and all its works, than is displayed in this, their own narrative of the brains and tact they brought to bear in negotiating with the Government?

Measles.

EVEN were it the case that the diagnosis of measles is a more simple matter than the diagnosis of any of the other notifiable diseases, the information would scarcely have been volunteered by any sane person negotiating to maintain the present scale of the notification fees. But it is not the case: the exact contrary is the case. Everyone outside the British Medical Association knows that in its most infectious—that is, its pre-eruptive—stage, the diagnosis of measles presents enormous difficulties. Except for the rare prodromal rashes, which are difficult to recognise, and Koplik's spots, which must be remembered before they are sought (and when present are not always characteristic) there is very little to guide the practitioner to differentiate between an ordinary harmless coryzal catarrh and a disease which, in its immediate results and late consequences, is now properly regarded as one of the most deadly and dangerous from which infants and young children can suffer. The disease, on which the British Medical Association elected to give the general practitioner away, was thus singularly, but characteristically, ill-chosen. This is how the interests of the profession are "looked after" by the self-satisfied bunglers at 429 Strand, London, W.C.

A CORRESPONDENT writes: "It may be true that in some 'Red Cross Hospitals' the wounded are being treated gratuitously by surgeons and physicians. It is certainly not so in all cases. While I am writing may I suggest that someone should lift up his voice to point out the egregious folly of making women 'Commandants' of Voluntary Aid Detachments, and thus placing them 'in command' of men?" The voices are there, ready to be lifted with a will, but to whom could such necessary protests be addressed with any prospect of success? SINAPIS.

The expenses of the Commission on Venereal Diseases were £3,585.

AVIATORS' SICKNESS.

THE translated article which appears in the columns of our present issue, under the title heading above transcribed, establishes the fact of the addition of a new item to our previously long-drawn-out roll of human maladies. It will also remind the thinking reader of the truth so invariably—and impressively—verified, at every forward step made by *Homo sapiens* in the advancement of intellectual culture, and in the promotion of physical enjoyment, something of counterbalancing evil never fails to present—*surgit amari aliquid*, to recall the highly applicable phrase of the most philosophic of all poets—which successfully discounts the value of the calculated gains; or even completely neutralises their anticipated value. Thus the air-plane, like the motor car, in its early stage of evolution, was found to function incidentally as the active sacrificial agent in the summation of the devotional rights of Nemesis after the joyous celebration of man's greatest mechanical conquest. To the abiding credit of the stimulus afforded by the last infirmity of noble minds, the enthusiasm of the inventive scientist and that of the practical voyager of the aerial ocean never faltered in presence of the inevitable physical dangers and drawbacks, and the astonished world was soon electrified by the respective single and duplicated cross-Channel flights of a Blériot and a Rolls.

The unprecedented rapidity of movement which has characterised the progress of aviation is most closely paralleled, perhaps, by the wondrous evolution of the "moving picture"—which, all so familiar as it has now become, can well sustain a claim quite as substantially based as that of the "wireless" or that of the air-plane, to the dignity of a modern miracle in its effective diminution of the measurements of our globe's latitude and longitude. Thus far has the rising generation of "our decadent race" been elevated on a spring-board of incalculable projecting power for the start on the Marathon cycle of human existence. The cinema takes no toll of life, and would seem to debit its votaries with nothing much worse than some nystagmic oscillation—and some pathological inoculation of juvenile morality, especially in the department of burglarious adventure, of which the possibilities are so frequently and meticulously displayed on the screen.

The features of aviators' sickness necessarily display a cousin-germanship with those of the *mountain sickness*, which has been so frequently rediscovered and redescribed since its original introduction to the expanding field of vision of Western Europe by the Spaniards, who had themselves been introduced to its intimate acquaintance for the first time on reaching the Peruvian Andes, and attempting to scale the previously unknown altitudes of the more inviting summits of the most majestic of all mountain ranges. There their Peruvian guides gave the newcomers an introductory description of the symptoms. There, too, the then benevolent and hospitable citizen of the community of the formerly graceful and glorious civilisation of the Incas made the ruthless "pale face" acquainted with the value of the *coca* prophylactic against the syndrome of

breathlessness and muscular fatigue with which the experiences of ages had made them familiar, and against which the benevolent Spiritual Father had furnished them a local vegetable prophylactic. Thus it was that Europe was furnished on the return of the Spaniards after the first trans-Andean expedition with a new and interesting *quasi*-clinical syndrome, and an effective and correspondingly interesting prophylactic: one of the relatively few loudly vaunted remedies which has been found to resist successfully the critical wear and tear of a series of centuries, and has continuously retained a place in the public eye—in some of its natural forms or modifying *Preps*: infusion, decoction, pill, lozenge, mixture, tincture, crystalline "active principle," or even stimulating wine. It is of practical importance, as well as historically interesting, to recall the fact that Southern America was then rapidly made to represent a new and teeming arsenal of the most powerful weapons for the conquest of disease. The druggist and the clinical physician were prominently in—very active—evidence, then as now; each was on the look-out for new and profitable material; each was already far too conscious that the reputation of many of the older infallible remedies had been worn threadbare at home, and that vast "business" prospects opened out in the far-off vistas of the then mysterious New World—with possibilities for the elaboration of new and unrivalled claims, which could be successfully discounted only after the expenditure of much and highly unprofitable laborious exertion. And here we find the illustrious physician, Monardes of Seville, the founder of the modern clinical reputation of therapeutic iron, furnishing the earliest armamentarium: Peruvian balsam, sarsaparilla, sassafras, guaiacum, tobacco (!), etc., etc. Many of our experienced readers have probably discovered for themselves, or through others, by this time, that the temptingly "convenient" use of preparations of active principles falls very short in the resulting clinical efficacy of that claimed for the old, crude, fresh preparations of the materials directly furnished by Nature. Some are still found, here and there, who are perverse enough to believe that of the now time-honoured quinine itself, attempts at the laboratory synthesis of which have hitherto failed in realisation—while producing innumerable interesting coal-tar by-products, which have been made to pay the expenses of those very costly procedures by the enterprising German firms who produced them accidentally; and had them certified in the rat-mouse-rabbit-guinea-pig hospital laboratory and thence transferred. . . ! Such is the history of the genesis and evolution of most of the synthetic products, the articles whose names terminate in an "ine"! This by the way.

The phenomena presented by the respective syndromes of mountain sickness and aviators' sickness are inevitably similar in many of their most characteristic features. The changes of atmosphere pressure and proportion of oxygen are the parallel factors in the two cases. The contrasting factors are: that in aviators' sickness we have the rapid transition to a highly modified medium, without any appreciable interval available for possible acclimatisation; while in mountain sickness we have a slow transition, which is very prone to be more than counterbalanced by the progressive muscular fatigue. It is gratifying to reflect, in conclusion, that the rapid scientific mastery of a novel and highly interesting syndrome is a characteristic feature of this rapidly moving age.

CURRENT TOPICS.

Torsion Injuries of Muscles of the Abdominal Wall.

IN the *New York Medical Record*, G. F. Boehme draws attention to the above. He defines the conditions described as being any injuries to the muscles or their attachments, caused by the sudden rotation of the body on its vertebral axis laterally, or the sudden extension of the abdominal muscles by a movement in the vertical plane. The four cases he has seen were brought about by the sudden throwing of a weight with the twisting of the body laterally. The traumatism was occasioned by the sudden contraction of the muscles of the abdominal wall against a resistance. There was a sense of something giving way with a sharp pain, and there was found to be an inability to repeat the attempt. In some instances breathing, where of the abdominal type, was painful and markedly limited. On examination a point of tenderness was made out, either in the rectus injured or in the oblique muscles (three cases). Sometimes a slight separation, as evidenced by a dimple-like depression on attempting to use the muscle, could be made out. Movements involving use of these muscles were much limited by pain at the site of the injury. The pathology of the process is simple. Apparently with the intense muscular strain certain fibres in the recti or oblique muscles are ruptured, and the tear creates a painful area within the muscle bodies. An adhesive plaster dressing was employed which has proved eminently satisfactory. An adhesive band, 2 inches in width, starting just external to the anterior superior spine of the uninvolved side, was carried around the body to the opposite side of the vertebral column. This was applied during complete expiration. From the opposite anterior superior spine a similar band was carried in the direction of the uninvolved external oblique, crossing the first band at the medium line and ending on the opposite in the back. As many bands were carried up the body as was necessary to immobilise the abdominal wall and to relieve the pain. The relief was instantaneous, the patient was able to resume work of a general variety, although torsion movements were interdicted. As a rule recovery ensued in about two weeks.

King Edward VII. Sanatorium.

WE have received a copy of the ninth annual report of the King Edward VII. Sanatorium, Midhurst, covering the year July, 1914, to July, 1915. It states that after the outbreak of war the number of applications for admission fell considerably, as did also the number of patients in residence. This is attributed to the uncertainty of the times, and to the prevalence of rumours that the military authorities were about to take over the institution. Gradually matters settled down, and the number of applicants approximated to normal. Reference is made to the reception, by arrangement with the War Office, of soldiers, mainly members of the Expeditionary Force, suffering from pulmonary tuberculosis. Fifty, and later seventy, beds were reserved for this purpose. The arrangement lapsed in June, 1915, when the National Insurance Commissioners became responsible for the care of consumptive soldiers. On account of the absence with the R.A.M.C. of the Pathologist and First Assistant Medical Officer, laboratory research has been suspended, though clinical work is still carried out. During the year 352 patients were discharged, of whom 258 were civilians, and 94 officers, non-commissioned officers and men from various branches of His Majesty's Forces.

The report states that three years of continuous

observation upon the use of tuberculin in diagnosis and treatment were completed at the end of the year 1914. It was then deemed advisable to discontinue this method of treatment until the immediate and subsequent results obtained at the Sanatorium since the adoption of tuberculin had been more fully worked out. Some years must necessarily elapse before the influence of tuberculin can be estimated with any certainty. The evidence as yet collected, however, does not suggest that the use of tuberculin increases, to any demonstrable degree, the efficiency of sanatorium treatment. On the recommendation of the Consulting Staff, a preliminary report upon treatment with tuberculin by the Medical Superintendent, Dr. Noel Bardswell, has been published. The difficulty of compiling statistics of ultimate results is emphasised. It is practically impossible to keep in touch, year by year, with every patient who has been discharged, and each year the task becomes more onerous. With the aid of a Government grant, an officer has been specially employed to make thorough search of old patients who have been lost sight of, so that the statistical returns are now more complete.

The Question of Milk.

AN evening paper remarks that "One of these days the people will rise in their wrath to demand something drastic in respect to their infants' food—milk. This topic grows old without growing respectable. While the limit of safety is put at 60,000 bacilli to the cubic centimetre, it is still impossible to get milk in London with a lower rate than a million bacilli, and in one district the rate is twenty-eight millions." At present milk costs 6d. per quart, which is the highest price, it is stated, within living memory. And worse remains, for there is general outcry that milk is dirtier and more adulterated than ever. A grave responsibility rests on Parliament in this matter. There is on the Statute Book an Act passed for the purpose of protecting the public against unscrupulous dairy farmers and milk dealers. This Act received the Royal Assent in August, 1914, yet has never been enforced. Parliament, in its wisdom, suspended its operation till six months after the war, the ostensible reason being the difficulty of obtaining the large staffs of inspectors necessary to carry out its enactments. The purpose of the Act is to make better provision with respect to the sale of milk and the regulation of dairies, and it was the opinion of the Local Government Board that the Act covers almost every point relating to the impurity and the impoverishment of milk. It enables the Board to make orders for the following:—

The registration with local authorities of all dairies.

The inspection by local authorities of dairies to see to the cleanliness of premises, the persons employed, and the utensils in use.

The prohibition of the addition of colouring matter, or skimmed or separated milk or water, or any other substance, to milk intended for sale for human consumption, or the abstraction from milk of butter-fat or any other constituent.

It is clear that an energetic use of the powers conferred by the Act will go far to check what can only be described as a flagrant scandal. With the approach of summer and the appalling prospect of widespread epidemic of "summer diarrhoea," the action of Parliament in suspending the enforcement of the provisions of this beneficent measure is to be deplored. Infant mortality, excessive now, must largely increase. The country's business at present is "killing Germans." We should see that we do not kill British babies. We know of no class of labour which can be less spared than that

required for the carrying out of the provisions of this suspended Act of Parliament. The whole question urgently requires reconsideration by a legislature which only meets three times weekly.

Worry and Insanity.

THE second volume of the annual report of the London County Council for 1914—"Asylums and Mental Deficiency"—contains a report by Dr. Mott, Pathologist to the Council, on the work accomplished in his laboratories during the year. An important investigation was that into the incidence of mental deficiency among the offspring of the insane in the London County Asylums. The families of 588 insane persons were investigated, and, according to reports received from the education authorities, only 15 (2 or 3 per cent.) of these had mentally defective children. Only 56 out of 573 parents had children after their first attack of insanity, and 106 children were born after the onset of insanity in the parent, whereas the remaining 1,259 children were born before the parent became insane.

Dr. Armstrong Jones, the Medical Superintendent of Claybury Asylum, emphasises in the report the influence of domestic trouble, stress, and anxiety on mental trouble. These factors justify the common belief "it's worry, not work, that kills." He has rarely, he states, seen insanity result from overwork alone—*i.e.*, apart from loss of sleep, fatigue, and ill-health.

Remedy for Street Accidents.

THE May number of the *Great Western Railway Magazine* points out that while street accidents in London caused by tramway-cars, motor-cabs, and private and commercial motor-cars were anything from 50 to 150 per cent. more in 1915 than in 1913, there was a decrease of 18 per cent. in the accidents caused by motor-omnibuses. This result is attributed in part to the reduction in the number of motor-omnibuses running, and also partly to the fact that the London General Omnibus Company have given their support to the "safety movement" initiated by the Great Western Railway Company two years ago, and have carefully coached their employees in "safety first" principles. By means of advertisements in the newspapers the company give useful advice to the public on the avoidance of street accidents. The cinematograph also is to be used, and it is hoped, with the assistance of the education authorities, to teach children how to avoid the traffic dangers of the streets.

The Treatment of Tetanus.

OUR French correspondent writes:—In cases of tetanus, Dr. Demmler (Academy of Medicine) uses much higher doses of chloral than the habitual 8 to 16 grammes per die. He pushes the doses to 20 and 25 grammes. He considers that in affections in which the nervous system presents a very marked hyperexcitability, the drug only becomes toxic when the nerve-cell has regained its normal functional state. He quotes in favour of this theory the high doses of opium (1 gramme and more) given in *tic-douloureux* of the face (Trousseau), of sulphate of strychnine (2 to 5 centigrammes) in delirium tremens (Luton), etc. Experience confirms his ideas on this subject. In tetanus he begins with a dose of 6 grammes of chloral, which is sufficient to induce sleep or analgesia. Six hours later he gives another dose of 6 grammes if the patient has not been calmed. He then increases progressively up to 20 or even 25 grammes. As soon as the patient sleeps soundly

enough not to be awakened by slight noises (people talking in a rather high tone or walking in the room) the doses are progressively diminished until they attain the amount usually employed, but they are immediately increased if nervous hyperexcitability reappears. The patient is placed in a separate room far from any noise, and the curtains are kept down. Dr. Capilan applied this treatment in a very serious case of tetanus, and although the patient had been considered as lost he made a complete recovery.

PERSONAL.

DR. H. LEIGH GILCHRIST has resigned his commission in the R.A.M.C. on account of ill-health and is resuming his practice at Carlisle.

DR. GEORGE PEARSON, resident house surgeon at the Victoria Central Hospital, Liscard, has resigned at the request of the committee in consequence of a protest by the honorary doctors against the employment of a single man, and a conscientious objector.

WE have been officially informed that the next Session of the General Council of Medical Education and Registration will be held in the new premises, 44, Hallam Street, Portland Place, London, on Tuesday, May 23rd, when Sir Donald MacAllister, the President, will take the chair at 2 p.m.

SIR WILLIAM MILLIGAN, M.D., consulting surgeon to Manchester Ear Hospital, and lecturer on Diseases of the Ear at the Victoria University, Manchester, suggests that the medical profession in this country express its disgust at the conduct of Dr. Aschenbach at the Wittenberg prisoners of war camp, by deleting from the honorary list of the Royal Society of Medicine the names of any Germans found thereon.

THE RIGHT HON. JOHN FREDERICK CHEETHAM, P.C., of Eastwood, Stalybridge, Cheshire, and Dukinfield Lodge, Manor Road, Bournemouth, Liberal M.P. for North Derbyshire 1880-85, and Stalybridge 1905-10, bequeathed £1,000 each to the Victoria University, Manchester, and the Ashton-under-Lyme District Infirmary. The woodland adjoining "Eastwood" he left to the executors to devote and set apart the same as a sanctuary or reserve for the fauna and flora of the district.

WE are glad to notice that Dr. Perry G. Goldsmith, who relinquished a large private practice in Toronto and came over to this country with the first Canadian contingent, has been promoted to Lieutenant-Colonel. He has done splendid service at Boulogne and Treport in France, and is now second in command at the Canadian Hospital, Folkestone. His compatriot, Dr. C. Cooper Cole, has, we regret to learn, been wounded whilst serving with Princess Patricia's regiment.

THE Queen has sent a contribution of £100 towards the special fund which is being raised by the Anglo-Russian Hospital Committee, 32, Victoria Street, for a field hospital of 100 beds and a fleet of motor ambulances to work with the Russian Army.

MR. WILLIAM COOPER, of Compton, Wolverhampton, bequeathed £100 each to the Wolverhampton and Staffordshire General Hospital and the Wolverhampton and Midland Eye Hospital.

DR. ALFRED LEWTHWAITE, late of Fulham Dispensary, has been appointed a tuberculosis officer of Essex County Council in place of Dr. W. R. G. Roberts, killed in action, at £500 per annum, with £120 a year for travelling and subsistence expenses.

CLINICAL LECTURE

ON

THE SYNDROME: "AVIATORS' SICKNESS." AN EXPERIMENTAL STUDY OF THE ARTERIAL TENSION DURING FLIGHT.

By M. G. FERRY, Aide-major de 2e Classe, Parc d'Aviation 6, France.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

WHAT are the sensations experienced in the course of their atmospheric ascents, by aviators, pilots and passengers? This is a question which everyone has asked himself on seeing one of those winged humans gliding across the azure vault of the heavenly canopy. The response is quite inevitably none of the easiest; and one of the special causes of the difficulty of answering is one which does not at once suggest itself. We find, on questioning the returned voyagers, the astonishing result that they form two groups of quite opposite views and facts of experience. The members of one of those groups freely avow the feelings of malaise with which they had been affected at the different altitudes—which had been attained more or less rapidly. The others, on the contrary, who would seem at first to form a much more numerous group, promptly erect the aviator's *amour-propre* into a defensive barrier against the intrusion of the curious; and accordingly, when questioned on the subject, formally and absolutely deny in definite fashion that they have at any time, or in any stage of aerial ascent, ever experienced even the slightest degree of malaise. So pronounced a degree of discordance obviously renders the matter of formulation of any general rules of practice in this connection a matter of extreme difficulty.

Being persuaded that even the most accomplished aviator must be quite incapable of analysing his own sensations during flight, wholly absorbed as his faculties must necessarily be in the supervision and management of his machine, and being ardently desirous to be able to make a choice of those two contradictory opinions, I determined at the time of my attachment as assistant physician to the Epinal centre of military aviation (summer of 1914) to take a flight as passenger. This fascinating experiment was repeated till I felt satisfied that I had accumulated a convincing series of data; and the reader will now, I trust, allow me to draw his attention to the resulting impressions—derived from sixteen ascents of variable duration, and reaching an altitude of 2,500 metres from the ground (= 2,850 m. above the level of the sea).

(1) *Subjective Study*.—During the stage of ascent—and varying with the velocity—the process of adaptation (slow or rapid) of the organism to the circumambient medium is punctuated by the development of various physiological troubles, which appear in irregularly serial order at variable planes of altitude. These, being often insignificant and transitory, may in many instances have escaped the notice of aviators who had not been warned of their occurrence. Of the serial items the principal are the following:—Headache, which frequently appears on passing beyond an altitude of 1,500 m. (Blériot), 2,000 (Farman); some *tinnitus aurium* at the same altitude—especially when the motor is placed behind the seat (M. Farman, for example), or when it is not rotatory; increasing difficulty of inspiration—associated with increased facility of expiration in the rarefied air; rapidity and tenacity of the pulse, according to the increase of altitude attained.

Those various unpleasant sensations seem to undergo a slight degree of attenuation on entering the horizontal plane of flight at the highest altitude attained. Nevertheless, when any disturbing incidents occur, such as results from the incidence of eddying currents, some slight repetition of the respiratory or cardiac troubles will be found to supervene—of emotional or reflex origin; subsidence, however, soon follows.

The descent is found to be productive of various sensations, which prove to be more sharply defined in proportion to the velocity and the degree of agitation during its course. The cephalalgia disappears—but at an altitude somewhat below that of its original onset. The respiratory movements return by degrees to their normal rhythm, the pulse becomes slower with a more vigorous stroke—although more gradually, as will be seen afterwards. On the other hand, the *tinnitus aurium* undergoes but a slight degree of subsidence, and persists even after reaching the ground for a period of which the duration varies with the form and situation of the motor (three to four hours when the motors are fixed at the back; half to one hour when the rotatory apparatus is arranged in front of the aviator). I can speak only from memory of the auriculo-tympanic shock produced by the act of deglutition during the course of the descent. It results, of course, from the brusque re-establishment of equality of pressure on the two faces of the tympanic membrane. The same factor also accounts for the disappearance of the painful sensation of throbbing strokes, in salvoes which synchronise with the pulse, and for the re-appearance of a clearer audition. When the descent is carried out in spirals of short radius and deep grades of descent, the machine being steeply inclined, palpitation of the heart sometimes appears which is apparently of emotional origin. In a case of this kind, I experienced two consecutive swoonings, which I had besides sought to provoke by watching successively the extremities of the two wings. They were of short duration, and disappeared when I was able to raise my eyes to the sky, and were reproduced during the course of other flights only under corresponding circumstances.

After returning to earth, a very obvious degree of nervous excitation succeeds the auricular tension and the other above-mentioned phenomena, which disappear pretty rapidly. This new development manifests itself:—

(a) Psychically, by a feeling of intense satisfaction, and one of enchantment of the voyage.

(b) In the sensory-motor apparatus, by a slight trembling of the extremities and muscular fibrillations (with frequently an impossibility of realising the amplitude with Dr. Pachon's oscillogometer, in the case of pilots who have just returned to earth); by a slight degree of inco-ordination of muscular movements, which seem to be uncertain and wanting in precision; and by a sensation of great lightness during the descent of the machine, sometimes accompanied by a sensation of titubation which rapidly disappears.

(c) In the cardio-vascular system, by flutterings of

the heart which quickly become calmed down; local congestions which are specially discernible on the face, notably in the eyes, the conjunctival membranes being markedly injected. I have never seen a development of nystagmus.

(d) In their other physiological apparatus, by an urgent desire to micturate, which often leads to a merely negative result; and by a distinct increase of appetite. All those phenomena disappear pretty rapidly, to be succeeded by a restorative sleep, which is profound in the majority of instances.

The question must now be discussed: In what proportion of other aviators have I met with those, the principal, sensations experienced by myself? Even if we can positively assure ourselves that all the passengers who have passed to a higher altitude than 1,500 m. in their respective first flights—a figure which, of course, increases with the progress of their training—have been affected at some period of their initial flight, we cannot calculate the proportion of pilots who feel corresponding symptoms at a proportion higher than 50 per cent. Among these, in fact, after every suggestion of the influence of *amour-propre* has been set aside, the inquiry is always one of the most delicate nature. Not merely the element of juniority, the element of variety of individual temperament counts for a great deal—inasmuch as the subjects of a nervous type are more sensitive than the apathetic. On the other hand, too, we have the facts that methodical training in regard to the duration and the altitude of flights; and also the degree of tranquillity, regularity and velocity—are all, individually and collectively, factors of importance in the training of each; and the gradual process of accustoming the candidate to the conditions and demands of his new vocation. The habitual use of one apparatus is also a factor of which the importance must be emphasised; and among numerous is the following typical example, observed by myself, which I here present to the reader: A certain biplane pilot, when flying as a passenger with a thoroughly expert monoplane, experienced—after a flight of half an hour at an altitude of 1,800 m., followed by a rapid descent—a series of novel sensations which he had never felt before.

II.—*Objective or Experimental Study.*—It was interesting to trace in the variations of arterial tension and of the pulse rate, at the different altitudes attained with more or less rapidity, an explanation of the physiological modification above referred to. I first undertook this investigation on two-seated machines, on the persons of some devoted pilots, but in the majority of instances the observations were made on my own person; and I trust that the reader will be able to bear with me while I lay before him a series of results which are inevitably much too personal.

A.—PULSE.—(a) On the Farman biplane (1913 model) and the Blériot monoplane, I counted my pulse at the entrance of each stage of 250 m., and have drawn the following general conclusions from the data so obtained: The number of pulsations per minute increases in proportion to the ascent with, upon the whole, approximate regularity. There is, of course, nothing surprising in this fact, since the strata of air traversed in the upward movement became gradually rarer and colder. This process of acceleration was at first very pronounced, from 0 to 750 m., appeared to subside from 750 m. to 1,250 m.; beyond the latter altitude it increased again and with greater rapidity. This result is explained by the fact that between the planes of 750 m. and 1,250 m. altitude, the air is usually more calm than in the inferior strata, while the wind is there more regular, the eddies are less numerous and always less sensible. Beyond the latter

altitude, with a wind current which is very often stronger, the degree of cold is above all a powerful factor in the new acceleration. On the other hand, I also noticed that every time the machine was roughly shaken by strong eddies, the pulse underwent a brusque acceleration, and again slowed down as soon as calm became re-established. A comparison of the results of my observations has also demonstrated the fact that, for the same altitude, the increase in the number of pulsations per minute was more pronounced in the ascents of a Farman than in those of Blériot.

MEAN DIFFERENCES.

Altitude between 0 and 1,000, Farman=17,
Blériot=14.

Altitude between 0 and 1,500, Farman=27,
Blériot=19.

As the Blériot ascended more rapidly than the Farman, the question here suggests itself: Did the heart experience a certain stage of retardation before accommodating itself to the environment of the new altitude which had been more rapidly reached?

(b) During the ascent to the maximal altitudes reached the pulse did not vary; and, as has often happened to me in a Blériot, very sloping evolutions during ascent—so-called Russian mountain exercises—produced no derangement of its rhythm.

(c) At the beginning of the descent, there appeared to develop, during an extremely short interval, a new period of acceleration; this was doubtless due to the slight degree of emotion provoked by the sudden cessation of the bruit of the motor, combined with the fact that the machine dived sharply at the same time. After this, the frequency diminished in regular progression, especially when the descent took place gradually and without any jerking movements. If the process was varied by very oblique elevations brusquely effected, shocks due to meeting with eddy currents (Obs. 9), the appearance of vertigo (Obs. 6: 2 slight successive swoonings taking place in the course of a rapid descent in spiral curves), glissades on the wing (Obs. 5: 2 glissades of about 100 m.)—a resulting acceleration was noticeable; of very short duration indeed, but sharply defined nevertheless. And after reaching the ground, the degree of diminution of the pulse-rate was less than that following a normal descent from the same altitude. Thus the degree of difference between the pulse-rate at the time of starting and that following the return to earth was more pronounced (Obs. 4: D=8; Obs. 5: D=14). As the experience of M. Cruchet had previously recorded, I always found the pulse-rate more rapid after the conclusion of a flight than it had been previous to the ascent; whether that had been carried out with regular gradation or been accompanied with acrobatic exercises (rising from 90 to 130 at the end of a quarter-hour's flight at an altitude of 800 m.).

Then another interesting fact must here be also noted: as the altitude reached increases during the ascent, the radial pulse becomes less perceptible, and becomes soft and unequal, while still retaining its regularity of rhythm. I have not, of course, been able to materialise those shades of distinction, inasmuch as any attempts at obtaining records by direct sphygmography or cardiography were out of the question—not only from the currents due to the velocity of the machine and the vibrations of the motor, but also from the difficulty of adjusting the inscribing style and maintaining its position in continuous contact with the registering cylinder, as well as that of the button on the radial artery.

B.—*Study of the Arterial Tension.*—The extreme readiness with which Pachon's sphyg-

momanometer lends itself to manipulation—the oscillations being but slightly disturbed by the vibrations of the air-plane—has enabled me to follow the variations of arterial pressure, both by itself and in association with those of the pulse-rate (Obs. 1 and 7), and during the respective stages of ascent (record taken every 250 m.) and descent.

(1) The graphic tracings thus obtained proved to be similar in all the cases, notwithstanding the fact that they were taken on various machines. A cursory examination of the tracings was then found to show that the curves of maximum and minimum pressure seemed to form the outline limits of an irregular spindle, the expanded portion of which corresponded to the maximum altitude attained, and of which the cone corresponding to the descent displayed a more rapid movement than that of the ascent. The question now suggests itself: Would there develop, in proportion to the altitude reached, a degree of more complete utilisation of the work of the heart—resulting from the diminished pressure exercised on the whole organism—with the effect of a facilitated systolic amplification of the general arterial system, especially throughout its peripheral segment, followed by a more complete cardiac depletion at each diastole? Or would the increased frequency of the cardiac movements explain by their associated phenomena of repeated excitation, and the integrated summation of the effects of the same, the increased amplitude and wider area of utilisation of the cardiac revolutions?

During the descent, which is always effected at a velocity greater than that of the ascent, the organism passes successively through strata of air of continuously increasing density. And, notwithstanding the persistent acceleration of the pulse, the range of separation, between the maximum pressure which goes on decreasing and the minimum pressure which goes on increasing, diminishes still more rapidly.

Another question here arises: Does the cardiac systole tend to diminish in vigour when it follows a cardio-vascular diastole of progressively increasing incompleteness? Or, would its normal effects be less vigorously sustained by the failing elasticity and retractility of the muscular tunics of the arteries? Would these also form the first symptoms of a cardio-vascular fatigue produced by the rapid descent?

(2) A detailed study of my tracings displayed the following data:—

A.—ASCENT.

DURATION OF ASCENT.

Machine: Farman ... Obs. 1 40 min.
 „ „ ... Obs. 2 35 „
 „ Blériot ... Obs. 7 30 „

INCREASE OF PRESSURE MAXIMA.

Between 0 and 2,000 = + $\frac{1}{2}$ cm.
 „ 0 and 1,750 = 0
 „ 0 and 2,000 = 0

DIMINUTION OF PRESSURE MAXIMA.

Between 0 and 2,000 = - $1\frac{1}{4}$ cm.
 „ 0 and 1,750 = - 1 cm.
 „ 0 and 2,000 = - $1\frac{1}{2}$ cm.

(1) The *pressure maximum* diminishes, at first, to a height of from 300 to 500 m. On passing beyond that elevation, the pressure displays a tendency to increase slowly and regularly, till it becomes equal or slightly superior to that recorded at the start.

(2) The *pressure minimum* diminishes continuously, rather rapidly from 0 to 500 m., and then less quickly. The diminution is more important, in every case, than the corresponding increase of the pressure maximum.

DURATION OF DESCENT.

Farman: Obs. 1 4 m. 48 s.
 Farman: Obs. 2 3 m. 30 s. or 3 m. 48 s.
 [time at 2,000]
 Blériot: Obs. 3 3 m. 10 s.

DIMINUTION OF PRESSURE MAXIMA.

From 2,000 to 0 = - $1\frac{1}{4}$ cm.
 „ 1,750 to 0 = - 1 cm.
 „ 2,000 to 0 = - $1\frac{1}{4}$ cm.

INCREASE OF PRESSURE MAXIMA.

From 2,000 to 0 = + $1\frac{1}{2}$ cm.
 „ 1,750 to 0 = + $1\frac{1}{4}$ cm.
 „ 2,000 to 0 = + 2 cm.

(1) Thus, the diminution of *pressure maxima* appears to become greater as the velocity of the descent is more rapid.

(2) The increase of the *pressure minima* appears to become greater as the velocity of descent is more rapid. This increase is, in every case, more important than the corresponding diminution of the *pressure maxima*.

Constant or Mean Pressure.—The study of this is easy:—

DURATION OF ASCENT.

Farman: Obs. 1 40 m.
 Farman: Obs. 2 35 m.
 Blériot: Obs. 7 30 m.

DIMINUTION OF MEAN PRESSURE.

From 0 to 2,000 = - $\frac{1}{2}$ cm.
 „ 0 to 1,750 = - $\frac{3}{4}$ cm.
 „ 0 to 2,000 = - $\frac{3}{4}$ cm.

DURATION OF DESCENT.

4 m. 48 s.
 3 m. 30 s. [3 m. 48 s. to 2,000]
 3 m. 10 s.

INCREASE OF MEAN PRESSURE.

From 2,000 to 0 = + $\frac{1}{2}$ cm.
 „ 1,750 to 0 = + $\frac{1}{4}$ cm.
 „ 2,000 to 0 = + $\frac{1}{4}$ cm.

(1) It is thus seen that it tends to diminish regularly during the period of the ascent; this diminution being more pronounced as the ascent takes place more rapidly (we know that during that period the pulse-rate continues to increase: the normal physiological association).

(2) During the descent it tends to increase. Nevertheless, the numerical equivalence of its increase at various periods does not enable us to make this augmentation a function of the time, and we cannot draw a definite conclusion therefrom. Then if specially a function of the altitude, should the gain be the same in Obs. 2 (at 1,750 m.) as in Obs. 1 and 7 (at 2,000)?

(3) *Collective Influence of an Ascent.*—What are the general modifications which an ascent in an air-plane can produce in an organism, of maximum, minimum, and mean pressure respectively?

A comparison of the measurements made at the respective times of starting and landing, and in the conditions most favourable to exactitude, furnishes the following results from cases of simple flights, of medium altitude and duration:—

	Duration.	Flight.	Altitude.
Farman: Obs. 1	44 m. 48 s.		2,000 m.
Farman: Obs. 2	38 m. 30 s.		1,750 m.
Blériot: Obs. 7	33 m. 10 s.		2,000 m.

Diminution of Maximum Pressure.	Increase of Minimum Pressure.	Diminution of Mean Pressure.
- $\frac{3}{4}$ cm.	+ $\frac{1}{4}$ cm.	- $\frac{1}{2}$ cm.
- 1 cm.	+ $\frac{1}{4}$ cm.	- $\frac{1}{2}$ cm.
- $1\frac{1}{4}$ cm.	+ $\frac{1}{2}$ cm.	- $\frac{1}{2}$ cm.

(a) Accordingly, there is a diminution of the maximum pressure, of a degree more marked as the flight has been of greater velocity: during the ascent and—more especially—during the descent.

(b) Increase of the minimum pressure under the same conditions.

(c) In all the cases there was diminution of the constant or mean pressure, and of the same order. (a)

Conclusion.—An ascent in an air-plane leaves after it a condition of arterial hypotension; and this is the more clearly marked as the ascent and, more especially, the descent have been more rapid. On the other hand, being called upon to adapt its systolic effort rapidly to circumambient circumstances, which are essentially and constantly changing, the cardio-vascular apparatus becomes quickly fatigued. This fatigue of helping to bring about at an early stage a degree of lassitude quite disproportionate to the amount of effort expended, as is observed in pilots after their circuits (who are sometimes found fast asleep near their machines in the open country). Why should we not attribute to the development of a certain degree of cerebral anaemia—the causation of which is referrible to two factors of clearly associated influence, cardio-vascular fatigue and arterial hypotension—the onset of those sensations of somnolence, fainting, and vertigo which are sometimes experienced by aviators, and referred, perhaps too hastily, to modifications of auricular tension: unequal degrees of pressure on the two faces of the tympanic membrane, hypertension within the labyrinth, or modifications in the conditions of the semi-circular canals? Should we not have also thus furnished a rational explanation of certain grave accidents of aviation, such as have occurred after rapid descents from places of very high altitudes (C—, after his crossing the Alps)? From these considerations, I regard it as highly necessary to advise all aviators to fly at a tranquil pace, and not fly too rapidly from one altitude to another. Not only will he avoid the development of the various forms of malaise referred to in the course of this communication, but he will also escape the fatigue of his cardio-vascular system, which tends to recur more rapidly with the frequent succession of flights; and, more especially, when such ascents, and more especially descents, have been effected too rapidly.

Then, on the other hand, in making choice of pilot pupils—putting aside all questions of candidates affected with any organic lesion of the heart, however slight, who should be systematically refused in every instance—it would be well to exercise a rigorous selection among those cases in which any visceral defect or diathetic blemish predisposes too easily to abrupt modifications of the circulatory régime.

MRS. HARRIET HARRIS, of Hackney, left estate of the gross value of £10,428, of which £10,262 is net personalty. She left the residue of her estate, subject to a few legacies and bequests, in equal shares to the Queen's Hospital for Children, Hackney, the Hackney Benevolent and Pension Society, the King's Nursing Home, and the Home and School for the Blind, Upper Clapton.

DR. ABRAHAM CROSS GODFREY, M.D., of Broom Hill, Dripsey, Co. Cork, formerly of Freemantle, Hants, late physician to the Southampton Dispensary, whose estate is valued at £48,365, left £1,000 each to the South Hants Hospital and the South Infirmary, Cork.

(a) Identical results were obtained in the cases of the pilots. As a typical case I may cite the hypotension of 0.25 c.m. in case of the aviator P. after a short ascent.

ORIGINAL PAPERS.

SOME POINTS IN CONNECTION WITH PUERPERAL ECLAMPSIA.*

By SIR WILLIAM SMYLY, M.D., F.R.C.P.

THE first point I wish to consider is what is puerperal eclampsia? How can it be defined. What does it include and exclude? The word eclampsia was, I believe, employed by Hippocrates, and signifies a lightning flash. Some say that it is derived from another Greek word which means to trick out. But to one like myself unlearned in the Greek language, and unfamiliar with the writings of Hippocrates, the origin of the word is of little interest. What does, however, seem to me to be of great importance is that when I use a word it should convey some fixed idea to those to whom I am speaking. Now, in general use, the word eclampsia is simply a synonym for convulsions, and in obstetric literature up to the latter years of the last century it signified convulsions occurring in a woman before, during or after delivery. But in 1893, Schmorl, and in 1895 Lubarsch published their epoch-making investigations into the pathological anatomy of puerperal eclampsia, and since that time the term has been used by obstetricians in a more restricted and technical sense, limiting its employment to those cases in which certain definite pathological conditions exist. When these conditions are present the case is one of eclampsia, even though the patient has no fits; and when they are absent it is not eclampsia, even though she may have convulsions. We now describe certain cases in which the patients became comatose and died, as eclampsia without convulsions, and others in which fits were due to uræmia, epilepsy, or other causes as convulsions, which were not eclamptic.

There is a condition which generally precedes convulsions, characterised by certain well-known symptoms: œdema, especially of the hands and face; diminished excretion of urine, associated with headache, nausea and vomiting. The urine on examination is found to contain albumin tube casts, renal epithelium, white, and sometimes red, blood cells. As the disease progresses towards its culmination in convulsions the patient complains of disordered vision and hearing, spots and splashes before the eyes, and, in some cases, complete blindness. The visual disturbance is generally associated with important anatomical changes in the eyes, such as retinitis and separation of the retina. A violent pain in the stomach is also not an infrequent symptom, and is generally a kind of aura ushering in a convulsion. Another symptom of great importance is a considerable rise in the blood pressure. In the text-books the condition I have here described is called either the pre-eclamptic state or toxæmia—both, in my opinion, bad and misleading terms. My objection to the first is that it suggests that the symptoms are merely a warning of danger to come, whereas they are in fact due to an actually existing and very serious disease which does not invariably, or even in the majority of cases, end in convulsions, and therefore the term pre-eclamptic appears to me to be wrong. The alternative term, toxæmia, is even worse, because it assumes what, though probably true, has never been established as fact, that the condition is due to a poison or poisons in the system. In my opinion these cases, whether they present the symptoms of the pre-eclamptic condition, convulsions, or coma without convulsions, are all examples of one and the same disease, and should be grouped under one name, whether it be

* Read before the Section of Obstetrics and Gynæcology, Royal Academy of Medicine in Ireland, 1916.

eclampsia or some new and better term. As far as we know at present, the essential facts connected with eclampsia are that it is met with only in women in the puerperal state or in the newly-born infants of eclamptic women. The blood is much thicker than normal, of high specific gravity, and contains, as Kollman discovered in 1897, an abnormal amount of fibrin, and, as Schmorl pointed out, a special tendency to coagulate in the blood-vessels. The anatomical changes found throughout the body after death by Schmorl and Lubarsch, appear to have been caused chiefly by this coagulation in the capillaries and the consequent necrosis and hæmorrhages into the tissues supplied by them.

The Kidneys showed thrombi in the veins and arteries of the small vessels, especially in the glomeruli with degenerative changes and necrosis of the tissues, especially of the secretory epithelium.

The Liver.—Thrombosis of the vessels with hæmorrhage and anæmic necrosis.

The Brain.—Thrombosis of minute vessels, with softening and minute hæmorrhages.

The Heart.—Thrombosis of vessels and muscular degeneration.

The Lungs.—Thrombosis and fatty emboli with hæmorrhages.

The same formation of thrombi with necrosis and hæmorrhages were found in all parts of the body, and are now generally accepted as the essential features of the disease; where they occur the case is one of eclampsia, and otherwise it is not. The hæmorrhages are usually minute petechiæ, but occasionally they are very extensive, and even cause death. We have long been familiar with apoplectic convulsions—that is, convulsions complicated by cerebral apoplexy—and I have seen very large effusions under the skin and into serous cavities, and I have no doubt that some at least of the cases of so-called accidental hæmorrhage are due to this disease. This opinion is founded upon the well-known fact that accidental hæmorrhage is generally associated with albuminuria, and also upon cases of which the following may serve as examples.

The first I have taken from Dr. Jellett's reports of the Rotunda Hospital. She was admitted on January 9, 1911, with a history of three eclamptic fits before admission. She had another fit after admission, and the usual treatment was carried out. Shortly after this she became collapsed, and respiration ceased. It was thought at the time, as I think very probably happened, that she had had another fit, and that respiration ceased during it. Her pulse rapidly became worse, and finally became imperceptible. Artificial respiration was performed, and stimulants, etc., administered without result, and it gradually became apparent that she was dead. *Post-mortem.*—Cæsarean section was performed as a chance of saving the child. On opening the abdomen it was found to contain sufficient blood to account for her rapid death. The blood had come from a ruptured mesenteric vein.

The second case was admitted to the Rotunda Hospital in March, 1915, under Dr. Tweedy's care. She was pregnant about seven months. Her face, legs and thighs were œdematous. She complained of intense headache, dimness of vision and vomiting; secreted very little urine, which contained numerous tube casts and became almost solid when boiled. The blood-pressure was 200 mm. hg.—in fact, a typical example of the pre-eclamptic state. The usual treatment was adopted, including purgatives and diuretics. All food was stopped, but she was allowed water *ad libitum*. Under this treatment she appeared to improve, but at the end of a week she suddenly complained of violent abdominal pain. A bloody discharge, which at first was slight

but gradually increased to a considerable hæmorrhage, escaped from the vulva; to check it the vagina was plugged, but though the external hæmorrhage was controlled her general condition grew steadily worse. The face became pale and cold, the features pinched, and her pulse rose steadily to 100 beats per minute. The abdomen appeared to be more distended, and the uterus was tender to pressure. The diagnosis was internal accidental hæmorrhage, and it was decided to extirpate the uterus as the only chance of saving the woman's life. On opening the abdomen, a considerable quantity of free blood was found in its cavity, the source of which was discovered in the right broad ligament, and a ligature thrown round the ovarian vessels on that side completely prevented all further loss. The blood already effused having been removed the wound was closed; the uterus not being removed. The patient made a complete recovery, and left the hospital in good health.

The third case came under my own care in December last. She had previously borne two children, one 12 and the other 10½ years ago. She was brought to me by Dr. Cecil Brew, of Bray, who informed me that he had first noticed toxæmic symptoms ten days previously, and that since that time she had been kept on an exclusively milk diet, but was steadily getting worse. When I saw her she had general anasarca, with puffy face and swollen eyelids, and the urine became almost solid when boiled with nitric acid. I ordered her to be confined to bed, gave her a cathartic mixture, reduced the milk to one pint in twenty-four hours, but allowed her to drink as much water as she desired. On the 29th, two days after, her condition was unaltered, her blood-pressure was 250 mm. h.g., and she passed 40 ounces of urine in twenty-four hours. I then stopped the milk altogether, but continued the water, and also allowed two teacupfuls of tea partly as a placebo and partly as a diuretic, and also some lemonade made with fresh lemons, which is supposed to favour the development of ante-thrombosis. From this time she appeared to improve steadily, the blood-pressure fell gradually, until, on January 12th, it measured 165 mm. The amount of urine excreted in twenty-four hours increased to about 60 ounces, and the albumin decreased very considerably. In a specimen examined by Dr. Éarl on the 14th he reported only one part in a thousand, and very few tube casts. The anasarca had entirely disappeared, and all her other symptoms had so markedly improved that I yielded to her earnest entreaty, and allowed her to go home. But only a short time afterwards Dr. Brew telephoned to me that there was some hæmorrhage, and that he would bring her into town at once. About half an hour later, on arrival at the nursing home, I found her weak and anæmic, but there was then no external hæmorrhage. Her general condition, however, became rapidly worse, and she fainted. On palpation the uterus felt hard and firm, and I could distinguish no fetal parts. There was evidently serious internal hæmorrhage, the symptoms indicating shock and loss of blood. To my great joy strong labour soon set in, and a dead infant, the placenta, and a large quantity of blood and liquor amnii were all expelled together. Pituitary extract was injected, and brandy and other restoratives administered, and as the uterus contracted firmly and there was no more hæmorrhage she gradually recovered, and has since gone on well. I think that in this case the premature detachment of the placenta was most certainly due to the disease of the mother, and I further hold that the disease was the same in all the three, though under the present nomenclature the first would be

classed under eclampsia, the second under toxæmia, and the third under accidental hæmorrhage.

The last point in connection with eclampsia to which I wish to refer is high arterial tension. It is an invariable symptom in this disease and the cause of some of its fatal complications, such as heart failure and effusion of blood. My attention was especially called to it by a case that I saw some months ago in consultation with Dr. Gibson. The patient was a primipara towards the end of pregnancy, who had albuminuria with other symptoms of the pre-eclamptic condition. These symptoms had been steadily growing worse in spite of her having been restricted to water for some days. Her urine was not only albuminous, but the chemical and microscopical examination pointed to serious degeneration of the kidneys. But what Dr. Gibson laid especial emphasis upon was that her blood-pressure measured 185 mm. h.g. We agreed that the pregnancy should be terminated without delay, and that the safest method under the circumstances would be Cæsarean section. That operation was accordingly performed by Dr. Gibson, with satisfactory results to both mother and child.

In this case I concurred with Dr. Gibson's views, because of the general symptoms and the history of the case, and was not at all influenced by the high blood pressure, about which I confess I knew very little. I did know that a high blood-pressure was a very constant symptom in eclampsia, and that 185 mm. hg. was a high blood-pressure. But whether it was unusually high in such cases, or what its prognostic value might be, I do not know, nor have I found much information upon the subject in obstetric literature. I therefore determined to utilise the opportunity which my present connection with the Rotunda Hospital affords to study it for myself. We had during the past year in the hospital thirteen cases of this disease, six of which were complicated with convulsions. In all the cases in which it was measured the blood pressure was very high, often up to 200 mm., and in some as high as 270 mm., but all recovered under the usual treatment systematised by Dr. Tweedy. A very high blood-pressure is not, therefore, a fatal complication, nor does it indicate the necessity for Cæsarean section. It is, however, one of the most important features in this disease, and one which requires most careful observation and treatment. Its reduction may be attempted in three ways. Firstly, by starvation combined with calloresis and diuresis. This was the method which we adopted with success in all our cases.

Another method for reduction of blood-pressure is by giving veratrium viride, but I have no personal experience of it.

The third method, and probably the most rapidly effective, is bleeding. This was the sheet anchor in the treatment of eclampsia by our forefathers, and was, in my opinion, abandoned upon insufficient grounds. Of late years it has again come very much into favour. Dr. Jardine practices it as a routine in all cases, and many excellent authorities in the United States, France and Germany most confidently recommend it. Commandeur, for example, declared that it was the most important remedy at our disposal, and Lichtenstein endeavoured to prove by statistics that all the benefits claimed for operations were due to the attendant hæmorrhage. In his tables he showed that after operative delivery convulsions ceased in one-third of the cases, and that those were the cases which had lost most blood. I myself believe that it benefits the patient not only by reducing the pressure but also by thinning the blood. We have not, however, bled any of our patients in the Rotunda.

My object in making this communication has not been to deal comprehensively with the subject of eclampsia, but rather to call attention to three points connected with it: Firstly that the pre-eclamptic state, convulsion, and coma without convulsions, are essentially one and the same disease, and should have one name. Secondly, to emphasise the connection between this disease and some cases of accidental hæmorrhage; and thirdly, to excite an interest in the study of the high blood-pressure in those cases, especially with regard to diagnosis, prognosis and treatment.

CARDIAC DISEASES AND DISORDERS IN WARFARE.

By CAREY COOMBS, M.D., M.R.C.P. LOND.,
Capt., R.A.M.C.(T.F.), 2nd Southern General Hospital, attached No. 32
General Hospital, British Expeditionary Force.

THE stress of work at the Southmead section of the 2nd Southern General Hospital has prevented any systematic investigation into the cardiac disturbances and lesions that have been encountered. Nevertheless, it may be worth while to report the most definite impressions that these matters have made on my mind.

First, there have been a fair number of cases of frank organic disease of the heart. I recollect but one example of the renal heart, in a man of about forty. His kidney lesion was obscure, and probably of long standing. His symptoms were cardiac, and it was on this score that he was invalided out. My own cases have only included one or two possible instances of cardiac syphilis, in the form of aortic valvular disease with some diffuse dilatation of the aorta. I have seen no case of aneurysm, though I believe one or two examples have been through the wards. Of post-rheumatic cases there have been quite a number. Many of these were obviously of long standing, but a few are traceable to rheumatic infection acquired, or at least manifested since the outbreak of war. With one or two exceptions they have been cases of moderate severity showing only a little enlargement of the heart and some mitral incompetence. The rheumatic group has also included several men with signs of aortic incompetence, and a few with evidence of mitral stenosis. I have seen no case of organic disease which can be directly traced to pure overstrain.

It might seem easy, at first sight, to decide what to do with these men. Anyone with organic disease should, it may seem, be discharged forthwith from the army. But since the prime consideration is whether or no the man is of most value to his country in the army or out of it, the problem is not quite so easy as it looks. Obviously men with pronounced cardiosclerosis associated with high tension are unfit for any kind of military service, and the same is true of cardiac syphilis. In both symptoms are almost sure to get worse quickly, and the man will become useless to the army, whereas he is still fit for years of work at home. In cases of rheumatic origin, most men with pronounced valvular lesions are of more service to their country out of the army than in it. Occasionally one meets with a case of aortic regurgitation or of mitral stenosis in a man who may be usefully employed at home in training recruits, or even in general home service. In arriving at such a decision as this, one is naturally influenced by the man's age, his term of service, and to some extent by his own inclinations in the matter. It is in patients with little or no dilata-

tion of the heart, and a mere systolic bruit at the apex, that most of the difficulties arise. Many of these men improve considerably in hospital. Those who have no symptoms, whose lesion is found accidentally, may be safely returned to duty. For others, who complain of dyspnoea on exertion, and in whom there is manifest cardiac enlargement, home service may be at least tried. The chief point is that no man should be discharged merely because he has *signs* of cardiac disease; *symptoms* are more significant than signs. Each case must be judged on its merits.

* * * *

A much larger group of cases consists of those who fall for the most part under the heading of "D.A.H." We have seen a great many of these, far more than in civil practice. Unfortunately, I have been able to get at my notes on only twenty-five examples of this syndrome. With these as a basis I will briefly describe the condition which they exemplify.

Ætiology.—The average age was 24, 76 per cent. of the men being 25 or under. A similar percentage was derived from infantry units. More often than not the patients are of slender physique. Various causes were assigned by the men themselves. Several had felt symptoms during training. In one or two some special effort or exertion was blamed, while others thought it was the outcome of the general stress, physical and emotional, to which they had been exposed. Here it may be remarked that the cases are more frequently met with among the Gallipoli men than among those from Flanders. In two cases the onset was directly attributable to shell shock, and in two others it was as certainly consequent on a wound. One man thinks his symptoms are due to excessive smoking during convalescence. This tobacco factor is not by any means discoverable in all cases. Yet it seems to me that many of these men, or boys, as some of them are still, are smoking too much in hospital. Finally, the symptoms appeared in some cases during convalescence from some acute infection, such as dysentery, from typhoid fever, or malaria. Some of the men seem to me to owe a fraction of their subjective discomforts to the attention which they bestow on their hearts after they have been told—unwisely as I think—that something is wrong with the heart.

Pathogenesis.—In the absence of any direct anatomical evidence, such data as are at present available must be pieced together. To begin with, there is no evidence in any of the cases I have seen of structural alteration in the heart itself, except of a mild, general dilatation, which—in some, at any rate—appears to be transient. On the other hand, there are distinct indications of a nervous or supracardiac origin. (1) The origin of the symptoms is often traceable to nervous shock or stress. (2) The pulse acceleration, which is so characteristic a feature of the syndrome, is subject in a majority to nervous excitation. (3) Certain of the more prominent physical signs, as will be shown below, are those associated in civil practice with states of nervous excitement. (4) The condition we are describing is often associated with other manifestations of an exhaustion neurosis. Of course, it is possible that there may be an intermediate toxic or even bacterial factor, and that nervous stress merely liberates some toxin or permits of some infection by which the symptoms are immediately provoked. Even so,

however, the nervous factor is by far the more important.

Symptoms.—The onset may be abrupt, and traceable to some definite event; or gradual, even coming on during rest in hospital or convalescent camp. There are three chief symptoms, dyspnoea with exertion or excitement, palpitation, pain or other forms of cardiac discomfort, also increased by nervous or physical stress, and giddiness. Headaches and sleeplessness are also complained of by some. In a few the hands are cold and blue, but this is by no means universal. In many cases there are no subjective symptoms. If a number of wounded, or convalescents from dysentery, be examined, the irritable pulse and other characteristic features of the syndrome are found in quite a large percentage.

The pulse variations constitute the most remarkable and constant feature of these cases. These variations may be noted under three headings: (1) The average rate is quicker than normal (over 80 per minute in over 80 per cent. of the cases). (2) The rate of the pulse varies widely from day to day, and even from minute to minute. The ward charts show this. In one of my cases the rates charted varied from 80 to 136, in another from 72 to 100, from 56 to 92 in a third, and so on. (3) The pulse is accelerated with notable readiness by comparatively trivial physical and psychical stimuli. The physical stimulus most easily applied is a change of posture. In one of my cases the following remarkable variations were recorded. The rate while the patient lay flat in bed was 132 per minute. When he sat up the rate increased at once to 156 and stayed at this rate for at least two minutes. When he stood up by the side of the bed it increased to 192 per minute, and a true alternation of beats became apparent, together with pallor and giddiness. For several minutes after he lay down again this high speed persisted. This is an extreme case, but the same increase of pulse rate with alteration in posture, persisting abnormally, is highly characteristic. Emotional or psychic stimuli are rather more difficult to improvise. The patients are, nevertheless, well aware of the fact that excitement causes a notable increase in the rate of the heart. One curious example of this is to be found in the fact that the pulse rate as measured by the medical officer during his round is invariably faster than the average rate in the chart—the interpretation, to which the patients themselves confess, being that the medical officer, with powers of discharge to duty, to subsidiary hospital, and so on, is a more formidable person than the sister, who is responsible for the pulse rates on the chart. The pulse is often irregular also, the arrhythmia being of the "sinus" type, *i.e.*, it is due to causes operating through the supracardiac nervous mechanism, and not inherent within the heart itself. In few cases extra systoles occur.

The *physical signs* are of some interest. The apex beat is forcible and diffuse, and extends too far to the left. Sometimes also it spreads downwards into the sixth interspace. There is, in fact, an apparently "inorganic" dilatation of the ventricles. Besides this there are limits of several kinds. These may be divided into three types: (1) A systolic murmur, brushing in quality, heard over a limited area, with its centre at or near the apex beat. This varies little with posture and respiration, but disappears after days, weeks or months. (2) A cardio-respiratory bruit heard at

the apex, along the left border of the heart, loudest during inspiration and with the patient in the erect posture, diminishing and even disappearing when the patient lies down and also during expiration. The resultant sound heard on auscultation is comparable to an interrupted jet of air or vapour during inspiration, dying off into silence during expiration. This is a very familiar accompaniment of nervous states in civil practice. I have described it fully elsewhere, and given reasons for assigning it to a pleuro-pericardial origin. The other types of limit, (1) and (3), own, I believe, a similar source. They tend to vary from time to time as type (2) does, and they have the same "near-to-ear" quality. In type (3) the bruit is also systolic, and as in (2) varies in intensity with posture and respiration; but it is heard chiefly along the left border of the sternum, and at the pulmonic cartilage. Types (2) and (3) may be heard at the same time, or they may alternate in the same case. In all three types the bruit is apt to occur later in systole than an ordinary mitral regurgitant murmur, and it may even have a "pre-diastolic" position in the cardiac cycle, running into and overlapping the second sound. In some cases no murmurs are heard at all. The first sound at the apex is nearly always accentuated.

Diagnosis.—The one great pitfall for the unwary is the case with which these conditions are misinterpreted as examples of organic diseases of the heart. Of the twenty-five cases spoken of here no less than seven came to us with a diagnosis of "V.D.H."—a fact of some importance in intensifying the patient's nervous instability. I have several times written down a case at the first rapid routine examination as organic, and likely to need a medical board, only to find, three or four days later, that the signs were already modified, and the condition manifestly "functional." To guard against mistakes of this kind the following points should be recollected. (1) No one should be condemned as a case of "V.D.H." on the strength of a murmur alone. To do so is an act of malpractice. (2) Every murmur should be studied in its relation to respiration, and in at least two postures, the erect and the recumbent. (3) Just as certain bruits are characteristically organic, others—such as those described above under (2) and (3) in "Diagnosis"—are characteristically "functional." (4) Often one examination is not enough. Diagnosis should be reserved till several have been made at intervals of three or four days or longer. (5) The presence of the "irritable pulse" is always suggestive of non-organic disturbance.

Prognosis.—Many of these men improve quickly in hospital. A few, however, persist in defiance of rest and all other attempts at treatment. Their ultimate fate is uncertain. Certain physicians who watched cases of the kind during the Balkan wars assert that if they are not cared for they drift into a state of permanent arterial thickening with cardiac hypertrophy. My own experience is not extensive enough in point of time to justify any statement, but it has at least shown me how obstinate and damaging to the soldier's career this condition of irritable heart may be.

Treatment.—So far I have failed to find any drug that is of use, with the possible exception of bromides. The one measure that has any effect is rest. This does not necessarily imply a long period in bed, though it is well to keep all such

men in bed for a few days if possible for the sake of observation. After this, if the average pulse-rate is not over 100, they may be allowed to get up gradually so long as they do not undertake any of the heavier ward work. The great point is to allow them a very long convalescence of some weeks or even months. It is the mental rest thus secured that helps them most. If at the end of their time they have improved sufficiently, they should be discharged to home service. Patients of this kind are never fit to go straight back to the nervous and physical stress of active service at the front. In some cases it is to be feared that they will never be fit for this. After a reasonably long probation they should be discharged from the army if shortness of breath still follows on moderate exertion and excitement. They will be more useful to the country making shells than being morally and physically knocked down by them.

One word may be said as to tobacco. On active service and during convalescence these men smoke a great deal. So far as is possible this should be controlled, especially in the case of the younger soldiers.

THE PROMPT CURE OF GONORRHOEA: PRINCIPLES AND PRACTICAL APPLICATIONS.*

By GEORGE A. WYETH, M.D.,
New York.

GONORRHOEA can be aborted, in the majority of cases, if seen within twenty-four hours after a purulent discharge has begun, except in primary cases. By "aborted" I mean cured within five to seven days, leaving the patient free of gonococci and all discharge, with urine clear, and able to withstand all provocative tests. Recent statistics as to the success of modern abortive methods vary widely, ranging from forty-five per cent, reported by Frank and Lewin, of Berlin, to ninety per cent, reported by Ballinger, of Atlanta. My own personal records of private practice show success in sixty per cent. of cases.

Gonorrhoea begins as a local infection and should be treated locally at the earliest possible moment. He who defers local treatment jeopardises his patient's chance of an early recovery. If progress is to be made in the cure of this condition, we must realise that, as in cancer, our best chances lie in early attack. The so-called conservative treatment, which postpones all local attention until the acute discharge has diminished, is a tacit confession that until the eleventh hour we rely upon Nature to rid the patient of gonococci. Such a procrastinating policy sacrifices the patient's most favourable opportunity of being rapidly cured by modern methods.

It is a peculiar thing that, in this country, in far too many instances, the term "abortive treatment" as used in the textbooks, appears to mean anaesthetising the urethra and the injection of some strong, highly irritating antiseptic, such as silver nitrate or mercury bichloride. Indeed, in the 1912 edition of Keyes, in the introduction to the subject of abortive treatment, I read, "In the production of chronic urethritis the abortive treatment has taken the place of the sound of our fathers." A little further on, in italics, appears, "the surest way to abort gonorrhoea is not to try to abort it." This is a very unfortunate teaching if it results in fixing in the

mind of the physician the belief that no patient who becomes infected with gonorrhœa can be cured within a few days. Whether or not the word "abortive" correctly describes the treatment, certain it is that a large proportion of patients with acute uncomplicated gonorrhœa, if seen within twenty-four hours after a frank discharge has been established, can be cured within five or six days, except in cases of primary infection.

In primary cases the infection makes more rapid progress than in secondary and later cases for the reason that the cylindrical epithelium of the virgin urethra once attacked by the gonococcus undergoes destruction. It is never regenerated as cylindrical epithelium, but always as pavement epithelium, which is less easily penetrated by the gonococcus.

From our studies of the pathology of acute gonorrhœa we know that the first effect of the entrance of gonococci into the urethra and their lodgment in the tissues is a simple inflammation with characteristic symptoms, and that the gonococci do not penetrate the stratified squamous epithelium of the fossa navicularis, but extend by continuity to the cylindrical epithelium of the pendulous portion, where they produce more marked changes. Here the mucous membrane is swollen and loosened, and covered by many layers of pus corpuscles. The capillary blood-vessels are markedly dilated, their lumen is filled to bursting with polymorph leucocytes, and their walls—except for the wandering out of leucocytes—show no changes. One of the striking features is that the inflammatory process is not distributed evenly over the entire surface of the urethra, but is predominantly lacunar and perilacunar. Another striking feature is that gonococci seen upon the surface of the epithelium and squeezed between the degenerated epithelial cells are practically all enclosed in the pus cells, while of those seen in the sub-epithelial spaces some are intracellular, but many more are extracellular.

Here, then, is Nature's battleground for her struggle against the invading enemy. She has dilated the blood-vessels to the utmost, and is sending forth her warriors, the leucocytes, to engulf the rapidly increasing army of gonococci by her usual means of defence, phagocytosis. The belief that the gonococcus is a parasite of polynuclear cells, in which it thrives, and that the extracellular ones are short-lived, I do not endorse. That the gonococci are found intracellularly is not due to any predilection of the gonococcus, nor is it a mere coincidence. It is a definite, specific act of Nature. If we incubate an emulsion of gonococci with washed human blood corpuscles for ten or fifteen minutes, after the method of Sir Almroth Wright, we find practically no gonococci within the leucocytes. But let us add an equal amount of fresh blood serum and incubate for a few minutes, and then we shall find the leucocytes filled with gonococci, just as happens with staphylococci, streptococci, etc. Again, gonococci are non-motile microorganisms, and it is fantastic to believe that they must depend for their existence upon some charitable leucocyte moving toward them to afford sustenance. The leucocytes that have performed their function of phagocytosis, and thereby contain gonococci, show no evidence of having been injured by the latter. Indeed, if gonococcal pus is stained with neutral red, the intracellular cocci are stained red, while the extracellular ones unstained. This procedure was used by Metchnikoff to demonstrate the secretion of an acid peptic fluid by the phagocytes, and the staining of the intracellular, and not the extracellular gonococci, shows similar secretion on the part of the gonorrhœal pus cells. As has been pointed out, gonococci seen on the surface of the epithelium are almost entirely intra-

cellular, while of those below the surface in the lower strata, some are intracellular, but many others extracellular. It is evident, therefore, that the gonococci are not dependent for their existence upon the protoplasm of the polymorph leucocytes. It has been my custom to examine microscopically the discharge of every patient at every visit, and it has been my observation that the new, well-developed cases, where no evidence of phagocytosis is shown, are invariably more stubborn in yielding to treatment than cases where the gonococci are mostly intracellular. It is in the latter group of cases that I feel vaccines are indicated, for I believe that the extent of phagocytosis and the degree of the opsonic index go hand in hand in this process. Finger failed to infect patients suffering from fever and general leucocytosis, and cases of spontaneous cure have been reported in attacks of pyrexia, to say nothing of cases that Nature herself has cured.

Since in the early stages of gonorrhœa Nature's mode of fighting the gonococci is by phagocytosis, the indication in treating this disease is to employ a remedy which, first, stimulates leucocytosis; secondly, acts as a mild gonococcicide; and, thirdly, cleanses thoroughly the urethra without injury to the tissues. Thus, in the early stages, the aim is to increase the discharge, and not to check it as has been the time-honoured custom. Nothing is more positively contraindicated than the prevailing use of astringents, which, by their constricting effect upon the mucous membrane and blood-vessels, hamper rather than assist Nature's remedial processes.

In my experience, after much experimenting chemically, bacteriologically, and serologically, the indications stated above are best met by the use of Neisser's own remedy, protargol, in a 0.25 to 0.5 per cent. solution, though I also advocate the use of any mild therapeutic agent, which fulfils the indications. Protargol itself so acts upon the urethra that its injection into a normal urethra produces a discharge macroscopically and microscopically identical with that of gonorrhœa, lacking, of course, the gonococci. In a two per cent. solution, however, protargol is astringent, like most of the popular silver salts, and in this strength is to be avoided so long as gonococci are present. The use of any strong astringent injection in this condition is to be condemned, as its mode of action is distinctly contrary to Nature's, and the effect is to predispose to complications as well as to chronicity of process.

If a patient is seen within twenty-four hours after a pus discharge has begun, a microscopic examination of the pus is made. Here at the outset we can determine the prognosis with a certain degree of accuracy by the microscopical findings, for it has been my observation that cases with a profuse purulent discharge, in which the leucocytes show that they are functioning by the pus corpuscles being filled with gonococci, invariably yield more kindly to this treatment than do cases with scant discharge in which gonococci are mostly extracellular. The patient is instructed to urinate into two glasses, passing most of the urine into the first glass and the last two or three teaspoonfuls into the second glass. If this second urine is clear and the patient gives no clinical evidence of a posterior involvement or other complications, we may hope to succeed with the so-called abortive treatment. By means of a Janet-Frank syringe with a Wheeler tip, the anterior urethra is flushed with 300 to 450 c.c. of a 0.25 to 0.5 per cent. solution of protargol, depending upon the intensity of the inflammation. The head of the penis is held firmly between the thumb and first finger of the left hand, the tip of the syringe is inserted into the meatus, and the solution slowly injected

until the anterior urethra is filled. The syringe is then slightly withdrawn, and the solution is allowed to flow out. Successive flushings are continued until the whole amount of solution is used, always with care that no undue pressure is exerted, as from the use of an elevated irrigator.

A hand syringe of at least two drachms' capacity is prescribed, and the patient is instructed how to inject the urethra himself every four hours, being told first to urinate and then slowly and gently inject the solution which is to be retained in the urethra for three minutes. This procedure is to be repeated, thus making two three-minute injections every four hours. Very often after such treatment, at the patient's visit the following day, I have found that the microscope showed no gonococci. In such cases a fairly encouraging prognosis may be made. Even if a few gonococci are still to be seen, there is no reason for discouragement as to the possibility of cure within five or six days. The initial treatment is repeated, and the patient reports on the following day, though more favourable results may be expected if the patient can be seen twice daily. No internal medicine is given, and no diet regulation is attempted, beyond the advice that the patient abstain from alcohol and highly seasoned foods. Exercise should be interdicted to prevent complications, and the patient is directed to drink freely of water.

After the third day, if no gonococci are found, the frequency of the patient's injections is decreased; and after the fourth day all treatment is discontinued, although the patient is kept under observation. Should he remain free of gonococci the case is said to be aborted. If, on the other hand, not all the gonococci have been eliminated, immediate treatment is again instituted and regulated by the microscope. Though our hope may not have been realised, yet we have at least the satisfaction of knowing that we have not unduly prolonged the attack, and that by continuing the treatment we can limit the duration of the gonococcal infection to from three to six weeks instead of the usual six weeks to three months.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CONSCIENTIOUS OBJECTOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is scarcely necessary to say that I do not "try to bolster up conscientious objectors." I do demand, and in good company, that the Tribunals expressly ordained to inquire into their minds should do so impartially. As the Bishop of Lincoln recently wrote to the *Times*, "the honest objector is safeguarded by the law, let him enjoy its protection." I merely echo the reasonable request of the Bishop that the law should do what it has undertaken to do. In many cases it has not done it. And its refusal to execute justice is naked Prussianism.

The more serious part of Dr. Claye Shaw's letter is its reiteration with little or no proof that "no such faculty exists as an innate knowledge of right and wrong." It requires some hardihood for Cambridgeshire to join issue with Weymouth Street, but I decline to receive Dr. Shaw's *ipse dixit*, traversing, as it does, the universal experience of the race. For the existence of conscience, in the Standard Dictionary sense, is far more than Christian dogma. I make no apology for adhering to the

Dictionary. Words mean what they pass current for, and I maintain that the volumes of that work have, in this case, carried out the aim expressed on their title-page: "to give . . . in the Light of the most recent Advances in Knowledge . . . the Meaning . . . of all the Words . . . in the Speech and Literature of the English-speaking Peoples." Nay, I will make myself yet more vile in Dr. Shaw's eyes, and appeal to the Smith's Latin Dictionary of our schooldays. Therein "conscientia" is illustrated by phrases, not from the Vulgate, but from Cicero. (*Vide in loco*, meaning III.) The conscientiousness of Divine guidance in critical times which Socrates claimed, was very different from the "conscientiousness" of Dr. Shaw. The ancient poets represented the terrors of conscience under such figures as the Erinnyes and the Furies, tracking down with swift and silent footsteps their guilty victims; the ancient myths had their Nemesis. All these have their modern counterparts in Tennyson's:

" . . . silent court of justice in his breast
Himself the judge and jury, and himself
The Prisoner at the bar, ever condemned;
And that drags down his life."

And to anyone who has read Dr. Paton's book, Dr. Shaw's explanation of the attitude of the cannibals is quite unconvincing. The last thing that would have occurred to Paton is that they regarded him as a *vis major*. Why, they were continually attempting the life of the *vis*, to say nothing of stealing from him and other annoyances. It was with them that the *vis major* lay, not with the missionary, and they showed in many ways that they were quite aware of the fact. The only adequate explanation lies in certain words of an older missionary: "The Gentiles, having no law, . . . show the work of the Law written in their hearts, the conscience witnessing with them, and their thoughts the meanwhile accusing, or else excusing, one another."

These words go to the root of the matter. In one way only can an adequate explanation be given of this universal phenomenon which men call conscience: that He Who made man put within him a sense of man's ultimate responsibility to his Maker. Training will modify, develop, enlighten, or darken it; the sense itself is a separate entity.

This will answer the case put by Dr. Shaw. City missionaries and others can testify that even in a child such as he describes, the sense of responsibility to a Higher Power is not entirely atrophied by years of warping and misdirection. The most remarkable instance of this is the very German nation to which Dr. Shaw alludes. "Brought up from their childhood to steal, to cheat, and to deceive," if so ordered by the state, they are manifesting in many cases, however tardily, decided doubt as to the rectitude of such conduct, as the letters found on dead German soldiers show. "That Germans as a whole will ultimately realise their national guilt is to my mind so sure that the contrary is almost inconceivable," wrote Mr. Arnold Bennett on May 13th, 1915; and although the time of figs is not yet, there are not wanting indications that his words will be fulfilled.

Moreover, there is a converse to Dr. Shaw's case. Instances have occurred during the Tribunal sessions where a parent has appeared with his son to explain that while entirely dissenting from his son's belief, he (the parent) was convinced that the belief was honest. Yet the son would have received his training from that parent.

And what of those crises in life when new sins tempt, and new virtues attract the soul? Will its response be conditioned merely by "modes of training, by emotion of fear, and by ideas of self-conservatism"? Such factors may have their

place, but they will be dominated by that volitional attitude whereby the man will embrace the lower or aspire to the higher—he will be true or false to his conscience. In other words, he will be governed by his innate knowledge and judgment of right and wrong. To which will follow either the “witness of a good conscience” or remorse, the latter being by no means proportionate to the emotion of fear. In support of this I cite from a host of modern witnesses a poet not specifically or aggressively Christian. I mean Mr. William Watson. No one who has read his verses on “Retribution” can forget the mingling of austerity and passion in the stanza following that wherein he sings how “We shape our deeds and then are shapen by them” :—

“They come upon our peace with sound of weeping,
They find us though we hide in clefts and caves.
They are with us waking, they are with us sleeping,
And rend us in our graves.”

It is a true word, and Mr. Watson’s plummet goes farther down into the depths than Dr. Shaw’s. Those emotions which we call guilt and remorse do not have their spring in training and environment, however they may be influenced by such.

I contend that a man making appeal in honest and good faith on the ground of the tremendous moral force which men call conscience, should receive what the law has promised him; and that, in the words of a recent protest by certain men of eminence, “Conscience, however mistaken, ought not to be a subject for public ridicule.” To quote once more from the Bishop’s letter, “the will or capacity to take an enemy’s life is not the only element in good citizenship.”

I am, Sir, yours truly,

Histon, Cambs., L. GWILLIM DAVIES.
April 27th, 1916.

MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The topics discussed in my previous letters form merely parts of the great question of Medical Law Reform, and if I am to be allowed to go on it will be under that heading. By Medical Law Reform I mean amendment of existing Acts and construction of new legislation which shall suppress the trade in fraudulent quack nostrums and appliances; which shall prevent practice by quacks under the cloak of that traffic, and shall prevent unqualified pretenders from assuming titles or by the use of misleading language in their advertisements palming themselves off upon the public as educated medical men.

Quackery in every phase is merely a system of getting money under false pretences. Much of this fraud might be put an end to by the appointment of an efficient department of public prosecution. This was proved in the now leading case tried before Mr. Justice Lawrence at the Lewes Assizes about six years ago. I do not now discuss the more subtle forms of quackery, some carried on under the mask of religion; nor do I write of fraudulent quackery within the profession—happily not more than a negligible quantity—with which I may deal later. I write now of forms of fraud as coarse as the coarsest of those amenable to the Foods and Drugs Acts, the Merchandise Marks Acts, and similar statutes. The Select Committee on Patent Medicines formulated a scheme of legislation which would deal with the worst abuses of the quack nostrum trade. It recommended that a great section of this trade should be stamped out by the sale and advertising of a large number of secret remedies being forbidden by law.

The question which has been suggested as to whether the Government of a civilised State is ethically justified in taking revenue from a fraudulent trade deeply injurious to the public welfare admits surely of only one answer. Patent medicines have been taxed for many years, but since they have been for the greater part now condemned by a special Government tribunal, they are evidently not fit to be touched for revenue purposes. Unless Mr. McKenna should himself tell us that he was aware of the findings and recommendations of the Select Committee when proposing to double the previous impost, no one who knows the facts will believe it. It is almost incredible that the necessary knowledge was not imparted to him by permanent Government officials, who were examined before the Select Committee. To raise taxes from a trade in great part fraudulent is to give sanction to the worst of that trade; and when the subject of Medical Law Reform comes within the sphere of practical politics this unfortunate slip will be made the most of in obvious ways by the enemies of reform.

It would be well if Mr. McKenna’s attention could be called to this deplorable business.

The Select Committee, large in number, was taken from among representative men belonging to every Party in the House, and its Report was unanimous.

After an enquiry extending over two years the Report was published in August, 1914. Its issue unfortunately synchronised with the outbreak of war, and the Report, among many other more and less urgent matters, was put aside until Parliament should resume its normal functions. The Report forms the most powerful weapon ever put into the hands of the profession for the promotion of reform, and if brought forward with proper backing at the right time, must at least force the question into the sphere of practical politics. It is possible that the task will be taken up by members of the Select Committee, but it is evidently most desirable that the medical profession should be made fully alive to the facts of the case, so that they may be able to speak with a voice the outcome of knowledge and inspired by real feeling. I would once more urge members of the profession to make themselves sufficiently acquainted with the Report of the Select Committee; its cost is only 3d. The large appended Blue Book, the “Minutes”—the evidence of witnesses verbatim, costs 6s. 7d. It is a volume which in human interest is, I am convinced, as amusing and instructive as any literary work of any class issued since it appeared, and is more than worth reading for its intrinsic qualities. The parenthetical observations which compose this letter have taken up as much space as I am entitled to to-day. I have still to finish my examination of the conduct of the newspaper Press and to discuss other topics which I have previously touched upon. With your permission I will return to these next week.

I am, Sir, yours truly,

The Old Rosery,
Earlswood Common.
HENRY SEWILL.
April 27th, 1916.

As prices are still rising, the Metropolitan Asylums Board, which maintains consumptive cases sent by the London County Council, has increased charges by $\frac{1}{2}$ per cent. Six months ago the charges were raised 10 per cent.

A HOSPITAL has been opened under the auspices of the Order of St John of Jerusalem at 87, Eaton Square. Offers of assistance should be made to the Administrator of the hospital.

SPECIAL REPORTS.

POOR LAW PAYMENT FOR "EXPENSIVE MEDICINES."

At a Council meeting of the Poor-Law Medical Officers' Association on April 14th, a letter was read from the Local Government Board in answer to an enquiry by the Honorary Secretary (Dr. Major Greenwood), as to whether drugs that had risen in price greatly during the war did not come under the description of "expensive medicines," and whether they should not be included among those that Boards of Guardians were required to furnish in accordance with the Circular of the Board, dated April 12th, 1865.

The following was the answer of the Board:—
Whitehall, February 24th, 1916.

Sir,—I am directed by the Local Government Board to advert to your letter of the 4th inst., and in reply to state that while they have recommended that "expensive medicines" should be supplied at the cost of Boards of Guardians, they have not issued any Regulations on the subject, and that the arrangements to be made in individual cases would depend on the terms of the agreement between the Medical Officer and the Guardians. The Guardians would no doubt be willing to take into account any case of an exceptional nature, if brought to their notice by the Medical Officer.—I am, your obedient servant,

E. A. ROWE (for Assistant Secretary).
Dr. Major Greenwood, Hon. Secretary,
Poor-Law Medical Officers' Association of
England and Wales.

The Hon. Secretary said that it was clear from this that the provision of "expensive medicines" was not compulsory on Boards of Guardians, and appeared to be only an act of grace on their part. That being so, they could not be compelled to provide the cost of drugs that had become expensive through the war. It would appear that the Guardians generally throughout the country had for many years agreed to pay the cost of certain drugs, and by raising the salaries of Medical Officers in not a few cases, during the war, had practically met the additional cost of drugs due to the war. It seemed to him that no further pressure could be put on them to do more at the present time.

The Council agreed with this, but thought that the Local Government Board ought to have made some regulation on the subject, and that a duty of this kind should be compulsory, and not merely permissive. If the recommendations in their Memorandum on the present Poor-Law Orders were carried out, all difficulties would be removed by the Guardians being obliged to find the drugs used in the treatment of their sick poor.

STATE-AIDED TREATMENT OF VENEREAL DISEASES.

MR. LONG, President of the Local Government Board, on April 14th received a deputation from the National Council for Combating Venereal Diseases, which presented a petition urging the importance of giving effect to the recommendations of the Royal Commission on Venereal Diseases, particularly as regards the provision of adequate facilities for diagnosis and treatment.

Mr. Long was accompanied by Mr. Hayes Fisher, M.P., Sir Horace Monro, Mr. F. J. Willis, Dr. Newsholme, Surgeon-General Sir A. May (Admiralty), and Colonel Barrow, R.A.M.C. (War Office).

The deputation was introduced by Lord Sydenham, President of the National Council, and it included Sir Thomas Barlow, Sir Malcolm Morris, Dr.

Frederick Taylor (President of the Royal College of Physicians), Sir Rickman Godlee, Major Darwin, Dr. Charles Porter, Dr. Helen Wilson, and Dr. O. May. Amongst the members who spoke were Dr. Frederick Taylor, Sir Malcolm Morris, and Dr. Helen Wilson.

Mr. Long congratulated Lord Sydenham and the distinguished members of the Royal Commission on the successful conclusion of their labours, and assured the deputation that so far as he and the Department were concerned they were pushing an open door. He informed the deputation that he had communicated with the Treasury, and they were prepared to provide the necessary grant to carry out the recommendations of the Royal Commission with regard to the provision of facilities for diagnosis and treatment. These grants would cover 75 per cent. of the cost incurred by local authorities. It was not proposed to create special hospitals for the treatment of venereal diseases, as it was felt that treatment would be carried out more efficiently and with less danger of prejudice at the existing general hospitals. In conclusion, Mr. Long stated that he welcomed an assurance given by the Bishop of Southwark that the movement would receive the full support of all the religious and social organisations of the country.

Mr. Long's announcement gives effect to the most immediate and practical recommendation contained in the Final Report of the Royal Commission on Venereal Diseases—namely, a comprehensive scheme for free diagnosis and treatment in general hospitals organised by local authorities and subsidised as to 75 per cent. of the cost by the Imperial Exchequer. Of the major recommendations this is the only one practicable through Departmental action only. The others—such as confidential registration of causes of death, legal protection for medical men in making certain confidential communications, and the making of venereal disease an incapacity for marriage—would, of course, require legislation.

A HOSPITAL AUTHORITY.

A STRENUOUS conflict on hospital management is recalled by the death, on April 16th, at Sydenham, of Mr. Burford Rawlings, at the age of 76. In 1866 Mr. Rawlings was appointed secretary to the National Hospital for the Paralysed and Epileptic, Queen's Square, W.C. When the new buildings (the Albany Memorial) were completed in 1885 he was given the additional title of general director. Mr. Rawlings's uncompromising insistence on the supremacy of lay control in hospital administration brought him into conflict with the medical staff, and a long controversy between the board of management, with Mr. Rawlings as protagonist, and the medical staff, resulted in the resignation in 1901, both of the board and of its secretary, who thus brought to a close his 35 years' service. The controversy was of more than local interest, and was kept before the public by a long correspondence in *The Times*. Mr. Rawlings was in some ways in advance of his day, as, for instance, in his contention that patients should pay for hospital treatment according to their means. He saw this at first strenuously opposed, and then adopted.

Mr. Rawlings contributed articles to the leading reviews, and was also author of "Gardens of Light and Shade," published under a pseudonym; of "The Waters of Argyra," "The Wooing of a Goddess," and other volumes of verse; and of "A Hospital in the Making." The last named is more than a history of a particular institution, and forcibly sets forth its writer's creed that "No greater misfortune could be suffered by the sick

poor than the severance of hospital work from its religious and benevolent bases, and its subjection to purely economic and scientific ends."

WITTENBERG MEDICAL HONOURS.

It is announced that the King has been graciously pleased to give directions for the following appointments:—

C.M.G. (ADDITIONAL MEMBER).

Major Harold Edgar Priestley, R.A.M.C. In recognition of his distinguished service and devotion to duty at the Camp at Wittenberg, Germany, during the typhus epidemic which prevailed there from February to June, 1915.

D.S.O.

For their share in the same work of devotion, the King has been pleased to appoint the following officers to be Companions of the Distinguished Service Order:—Capt. Alan Cunliffe Vidal, R.A.M.C., and Temp. Capt. James La Fayette Lauder, R.A.M.C.

The revolting story of the crime of Wittenberg Camp, where British and other prisoners of the Allied nations suffered terrible privations owing to the inhumanity of the German military authorities, was told in a report published by the Government Committee on the Treatment by the Enemy of British Prisoners of War.

OBITUARY.

DR. FREDERICK LEVER, M.B., B.S., M.R.C.S., HARROGATE.

THE death of Dr. Frederick Lever, of Montpellier Lodge, Harrogate, occurred on April 16th, in his 69th year. Dr. Lever had been observed recently to be in somewhat failing health, and for a few days suffered from dyspeptic symptoms, which resulted in acute cardiac failure. He was a member of an old medical family, his grandfather and father being prominent members of the profession. The son of the late Mr. Benjamin Lever, surgeon, of Blakesley, Northamptonshire, he was educated at the Royal Epsom Medical College, and received his special medical education at Guy's Hospital, where he took the Sands-Cox Scholarship in Physiology in 1882. He became a B.S.Lond. in 1882 and M.B., B.S.Lond. and M.R.C.S. in 1885. He commenced practice in Harrogate 30 years ago, and from the commencement was a prominent member of the Harrogate Medical Society, of which he was twice elected president. He always took a great interest in the advancement of Harrogate as a spa, and especially in comparison with the watering-places of Europe, and joined heartily in all efforts in the welfare of the health resort in that direction. Although somewhat retiring, he was an extremely genial and courteous gentleman, well informed, and possessed a good scientific knowledge. He devoted himself to the interests of his profession, refraining from participating in the public life of the town. He leaves a widow, son and daughter.

LIEUT.-COL. W. WOODFORDE-FINDEN, M.R.C.S., L.R.C.P. LONDON.

LIEUTENANT-COLONEL W. WOODFORDE-FINDEN, brigade surgeon in the Indian Medical Service, died on April 27th, in a nursing home after a long illness. The only son of the late George Corfield Finden, he received his medical training at King's College Hospital, qualifying M.R.C.S.Eng. in 1865, and L.R.C.P.Edin. in the following year. He obtained his first commission on October 1st, 1866, and afterwards did duty with the 94th Foot, the 11th Bengal Cavalry, the 2nd Gurkhas, the 13th Bengal Infantry, and the 7th Bengal Cavalry. He was on Lord Lytton's staff at Simla in 1876 and on Sir Donald

Stewart's Staff in Afghanistan, 1878 to 1880. Colonel Woodforde-Finden took part in the march from Kabul with Lord Roberts to the relief of Kandahar and the battle of Kandahar, was mentioned in despatches, and was awarded a medal with clasp and the bronze star. He served in Burma, 1887 to 1888, and on the North-West Frontier of India, second Miranzai Expedition, 1891, obtaining another medal with clasps for these undertakings. He retired on December 21st, 1891.

DR. W. ALLAN JAMIESON, M.D., LL.D., F.R.C.P., EDINBURGH.

DR. WILLIAM ALLAN JAMIESON, President of the Royal College of Physicians, Edinburgh, in 1909-10, has died at his residence in Edinburgh at the age of seventy-seven. Educated at the Universities of Edinburgh and Vienna he graduated M.B., C.M.Edin. with honours in 1865. Devoting himself to the study of dermatology, Dr. Jamieson attained a high position in his profession. A successful teacher, he was for many years lecturer on diseases of the skin at Edinburgh University, and dermatologist to the Edinburgh Royal Infirmary. He was surgeon to the King's Body Guard in Scotland, the Royal Company of Archers, was an LL.D. of Edinburgh, and a Knight of Grace of the Order of St. John of Jerusalem in England. He held the Royal Household Jubilee medal of 1897, and the Coronation medal of 1911. Dr. Jamieson was the author of a "Manual of Diseases of the Skin," which has passed through several editions, and of the "Care of Skin in Health," and had contributed various papers to professional publications on dermatology and its allied subjects.

DR. JOSEPH W. SMITH, M.R.C.S., L.M., L.S.A., J.P., NORTHWICH.

THE death occurred suddenly at Northwich, on April 13th, of Dr. Joseph William Smith, at the age of seventy-five. Dr. Smith was the doyen of Mid-Cheshire men. After a medical training at King's College Hospital, he qualified M.R.C.S.Eng., L.M., and L.S.A. in 1866. He had been in practice in Cheshire for many years, and in addition to his professional duties, had taken a prominent part in public affairs. He was appointed a magistrate of the county in 1895, and had been a county councillor. He died in harness, as it was on his return from a meeting of the Cheshire Appeal Tribunal that he had a seizure which resulted in his death. Dr. Smith was the Union Medical Officer, and had held the posts of Surgeon to the Northwich Infirmary and of the Northwich and Weaverham Provident Dispensary. He was held in high esteem, and a few years ago the inhabitants of the district presented him with a motor car and garage.

DR. JAMES BROWN BIRD, M.D., CARLISLE.

ON Saturday, Dr. J. B. Bird, one of the leading practitioners in Carlisle, died suddenly of pneumonia. He was a native of Newcastle, and took the degrees of M.B., C.M., in 1890 at Edinburgh University, where he was Stark scholar. In 1897 he graduated M.D. After acting as house physician to the Brampton Consumptive Hospital and assistant medical officer to the Crichton Institution at Dumfries, he became house surgeon at the Cumberland Infirmary and subsequently started general practice in Carlisle. He was physician to the Cumberland Infirmary. He took a great interest in the Association for the Prevention of Consumption, and was one of those who greatly assisted in the establishment of the sanatorium at Blencathra. Dr. Bird was one of the founders of the Carlisle Burns Club, to which he contributed papers. He was 50 years of age, and is survived by wife and family.

DR. JAMES MORRISON, M.D., M.R.C.S., L.R.C.P., LONDON.

DR. JAMES MORRISON, of Weymouth Street, Portland Place, London, W., died at his residence on Good Friday, and on Easter Monday the death occurred of his widow, Mrs. Morrison. Dr. Morrison

studied at St. Bartholomew's Hospital and in Berlin, and qualified M.R.C.S., L.R.C.P., in 1892. In the following year he graduated M.B. London, and took the M.D. degree in 1894. He had been tutor in midwifery at St. Bartholomew's Hospital, Resident Medical Officer of Queen Charlotte's Hospital, and honorary Physician Accoucheur to the Queen's Jubilee Hospital, and also held the latter position at the Farringdon Dispensary and Lying-in Institution.

DR. CHARLES JOHN GRELLET, M.R.C.S., L.S.A., HITCHIN.

THE death occurred on April 26th, at the age of 73 years, of Dr. Charles John Grellet, a prominent medical practitioner in Hitchin. Dr. Grellet received his medical training at St. Bartholomew's Hospital, and qualified M.R.C.S. London and L.S.A., in 1864. He had practised in Hitchin for many years, latterly with the assistance of his two sons. He was consulting surgeon to the North Herts and South Bedford Hospital at Hitchin.

DR. FRANK C. P. HOWES, M.D., LINCOLN.

DR. FRANK CHARLES PLUMPTRE HOWES, who has died at Lincoln, was a son of the late Rev. T. G. F. Howes, rector of Belton, Suffolk. He studied for the medical profession at King's College Hospital, London, and at the University and Royal College of Surgeons, Edinburgh. In 1863 he qualified L.S.A. London, and graduated M.D. Edinburgh in 1864. He was admitted M.R.C.S. Eng. in 1865 and L.R.C.P. Lond. in 1868. He had been resident medical officer at the Eastern Dispensary, Bath, resident surgeon at the Aston Branch of the General Dispensary, Birmingham, house surgeon at the General Dispensary, Lincoln, Bradford Infirmary, and Kensington Dispensary.

MEDICAL NEWS IN BRIEF.

West London Medico-Chirurgical Society.

A RECEPTION will be held at the West London Hospital by the President and Council of this Society on Wednesday next, May 10th, at 8.30 p.m. An interesting programme of music and other entertainment will be provided by members of the Savage Club and others. Mr. James Cantlie, F.R.C.S., will give an address on the work of the British Red Cross Society. There will be exhibits of Red Cross methods and appliances by the Hammersmith Division of the British Red Cross Society, and by Messrs. E. and R. Garroul, of Edgware Road, W. Skiagrams and scientific instruments will be shown by Dr. Reginald Morton, assisted by Messrs. Newton and Wright. Light refreshments will be provided. Members are asked to bring guests, and ladies are particularly invited. Tickets 5s. each person, and the whole of the proceeds after paying expenses will be given to the Officers' Families Fund to be specially devoted to the families of Officers of the Royal Army Medical Corps.

Preservation of Food.

DR. HOWARTH, the City of London Medical Officer of Health, in a report to the Corporation on the tendency to put boric acid in food products without any form of control, says there is a conflict of opinion as to the harmfulness of boric acid. He suggests research work by the Local Government Board to clear up this uncertainty. If boric acid is harmful to human beings, a statement, he says, should be made definitely to that effect.

Teachers' Conference and Child Health.

AT the Conference of the National Union of Teachers, at Buxton, on April 27th, Mr. T. P. Sykes (Bradford), a former president, moved that "This Conference, considering the physical development of young children is a matter of supreme national importance, and that any present neglect of necessitous or delicate children must result in permanent injury to the individual and to the State, urges local

authorities to see that such children are in no way neglected." Notwithstanding present demands consequent on the war, he said, Bradford was already showing in a practical manner what really ought to be done all over the country.

Miss E. Phillips (Cardiff), who seconded, said it was impossible to walk about the large towns and villages without seeing signs of hunger and preventable disease. They saw little children with pinched faces, weak bodies, scantily clothed, badly nourished, and it was their place to see that such children were properly clothed and fed, whatever the cost.

The motion was carried.

Royal Waterloo Hospital Centenary.

In commemoration of the 100th birthday of the Royal Waterloo Hospital for Children and Women a great meeting of its supporters was held on April 27th afternoon at the Mansion House. The Lord Mayor presided.

During the 100 years of its existence the Royal Waterloo Hospital has, the Lord Mayor stated, treated over a million patients, the great majority of them being children. It has now over 100 beds, and last year there were nearly 1,200 in-patients and about 40,000 out-patients.

At the conclusion of the meeting the Lord Mayor announced that the amount so far received in response to the Duchess of Albany's appeal was £1,807 4s.

Royal College of Surgeons of England.

THE following demonstrations of specimens in the Museum will be given in the Theatre of the College in Lincoln's Inn Fields, by Mr. S. G. Shattock, the Pathological Curator, at 5 o'clock p.m. each day. Monday, May 1st, 5 p.m., Fractures. Monday, May 8th, 5 p.m., Foreign Bodies. Monday, May 15th, 5 p.m., Results of Inflammation.

The demonstrations are open to medical students and practitioners. First-aid and ambulance students desirous of attending, will also be admitted.

Tubercular Patients and Sanatorium Treatment.

AT a meeting of the London Insurance Committee, Dr. J. E. Squire, medical adviser, reported that although the number of contributors had diminished owing to enlistment of healthy young adults, the candidates for sanatorium treatment had not diminished in anything like the same proportion. He suggested that tuberculosis officers should avoid keeping early cases under dispensary treatment before putting them forward for sanatorium admission, and that an endeavour should be made to persuade medical practitioners to recommend early cases at once rather than keep them under domiciliary treatment. At the same meeting it was decided that the sub-committee dealing with the recruiting of panel practitioners should submit to the military representative a list of persons whose services in dispensing medicines are indispensable to the need of the general population.

Lady Kelvin's Bequests.

AT the Court of the Glasgow University on April 27th, it was stated that by her will Lady Kelvin bequeathed £5,000 to be applied for promoting research and the teaching of physical science in connection with the Chair of Natural Philosophy at Glasgow University, where Lord Kelvin was Chancellor at the time of his death. Lady Kelvin also bequeathed to Glasgow University all the decorations and medals conferred upon the late Lord Kelvin. This is a rare collection, and will prove a valuable addition to the University museum. The gifts were gratefully acknowledged.

Carlisle School Doctors.

THE point as to whether the services of the two medical officers of Carlisle in the medical inspection and treatment of the school children of the city is more essential in the national interest than their services in the Army was the subject of considerable discussion at the meeting of the Carlisle Education

Committee on April 26th. In response to an inquiry from the Board of Education, a sub-committee recommended that the Board be informed that having regard to the importance of the service of the two doctors, they should be retained in their present position until the utmost urgency existed for their withdrawal.

Mr. F. Ritson moved that the recommendation be deleted from the minutes. He said the doctors could be more advantageously employed in the Army Medical Department than in compiling a mass of statistics as to how many children had ringworms or itch. The sub-committee's recommendation was adopted by six votes to five.

Bolingbroke Hospital.

At the annual meeting of the Bolingbroke Hospital, held on April 28th, some concern was expressed with regard to the financial position owing to the increased prices of many articles. The report showed that expenditure had exceeded revenue by £1,487. The chairman (Mr. E. J. Thorne) urged that friends of the hospital should, if possible, increase their subscriptions, and he expressed the hope that the people of the neighbourhood would rally to its support. The Vicar of Battersea (the Rev. H. Foster Pegg) was elected a Governor.

St. Paul's Hospital.

THE annual meeting of St. Paul's Skin Hospital was held on April 28th. The chairman, Mr. Frederick Cowper, explained that five of the surgeons had gone abroad on war service, and that three of the staff were also engaged on military hospital work in London. In view of the possibility, anticipated by the Royal Commission on Venereal Diseases, that the curative resources of the hospital may be heavily taxed for many years after the war, the chairman solicited the support of the charitable public in order to equip the hospital for such an eventuality, as well as to enable the Committee to clear off the debt of £2,000 and to secure larger premises. In accordance with the recommendation of the Royal Commission, the Committee had been able to secure a public source of revenue for the supply of remedies to necessitous patients.

Infant Welfare.

In the House of Commons, on April 13th, Mr. Long, replying to Mr. King, who asked whether he would issue instructions to local authorities that an expenditure not exceeding $\frac{1}{2}$ d. in the pound might be judiciously undertaken, even in war-time, on promoting infant welfare and combating infant mortality, said:—I have already encouraged local authorities to undertake work for the promotion of infant welfare, and Parliament has been asked to vote money for furthering their efforts. I do not think that anything would be gained by an instruction such as is suggested.

Royal College of Surgeons of England—Prizes.

THE subject for the "Triennial Prize," consisting of the John Hunter Medal executed in gold to the value of fifty guineas, or, at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of fifty pounds, will be "The Development of the Hip-Joint and the Knee-Joint of Man." That for the "Jacksonian Prize" (the amount of the dividend, £15, received from the Trust), is, for 1916, "Methods and Results of Transplantation of Bone in the Repair of Defects caused by Injury or Disease," and for next year, 1917, "The Causation, Diagnosis, and Treatment of Traumatic Aneurysm, including Arterio-Venous Aneurysm."

Conditions:—Candidates must be Fellows or Members of the College, not on the Council; the dissertations should be addressed to the Secretary and be *typewritten* in English, the number and importance of original facts will be considered principal points of excellence: *cited cases to be placed in an appendix*. Each dissertation to be distinguished by a motto or device; and accompanied by a sealed

envelope containing the name and address of the author, and having on the outside a motto or device corresponding with that on the dissertation. Those dissertations which shall not be approved, with their accompanying drawings and preparations, will, upon authenticated application within the period of three years, be returned together to the respective authors. The dissertations for the Triennial Prize must be delivered at the College not later than 4 o'clock p.m. on Tuesday, December 31st, 1918. Those for the Jacksonian Prize for the present year, 1916, before December 30th; and those for the Jacksonian Prize for the ensuing year, 1917, must be delivered at the College before December 31st, 1917.

American Red Cross Work in Germany.

THE question of the shipment by the American Red Cross of hospital supplies to Germany is again discussed. It is asserted that, in default of permits to pass the blockade, the American Red Cross is obliged to notify its branches that no more supplies can be received for Germany. It is believed that Great Britain will continue to refuse to allow shipments unless the American Red Cross should establish units in Germany, in which case supplies would, of course, be allowed to reach these units.

Herb-Growing for Profit.

THE Herb-Growing Association, of which Miss Alice Sandford is chairman, and whose offices are at No. 7, Queen Anne's Chambers, S.W., has issued its first monthly circular. It gives information of use to people who have the time and the necessary botanical knowledge to undertake the gathering or growing of common herbs.

Among the most useful herbs to cultivate or gather are the dandelion, the roots of which are washed and dried; coltsfoot, whose yellow flowers now gleaming on railway banks and waste places will be soon followed by the leaves which are dried for medicinal purposes; broom tips, the male fern, and the autumn crocus. The association has established a drying shed and warehouse at Bridge Farm, Weybridge, and will undertake to dry the herbs for members. It will also sell them on commission. As much as 60s. a hundredweight is offered for dried dandelion roots and 23s. for a similar quantity of male fern root.

A Year's Infectious Disease.

A LOCAL Government Board return, issued on April 10th, shows the total number of cases of the chief notifiable diseases in England and Wales during 1915. The following are the principal figures:—

Tuberculosis (pulmonary) 73,358, ditto (other forms) 22,864, scarlet fever 127,086, diphtheria 53,597, enteric fever 6,364, puerperal fever 2,057, erysipelas 23,382, cerebro-spinal fever 2,566, poliomyelitis 517, ophthalmia of the newly-born 6,806 (being 8.34 per 1,000 births).

Of the 90 cases of small-pox, 31 cases were notified from towns connected with ports. Of 45 cases of typhus fever, 37 were notified in Liverpool. Of cerebro-spinal fever the highest numbers of cases in administrative counties were notified in—Middlesex 115, Southampton 110, Wiltshire 108, and Kent 106. In London 624 cases were notified.

Harrogate Baths Development.

At a meeting of the Harrogate Town Council Mr. J. S. Rowntree emphasised the importance of the Harrogate bath treatments being kept up to date, particularly when Continental spas were closed, and said the Baths and Wells Committee were now introducing a shallow bath for the Harrogate peat massage treatment, which was not being given anywhere else in the world. A bath which would enable rheumatic patients to adopt different attitudes and relieve their pains whilst bathing was being installed, and also a whirlpool bath for softening parts of the body requiring massage. The committee were also awaiting the development of the Simpson light, which would form a new development of the X-ray treatment.

Bad Teeth and Tuberculosis.

DR. A. M. HEWAT, tuberculosis officer for Preston, in his annual report deals with the question of the dental treatment of patients attending the tuberculosis dispensary, and says it is a sheer waste of money to send patients to the sanatorium or to give them drug or vaccine treatment at the dispensary if their teeth are in a condition of decay and there is septic absorption.

Hospital for Canadians.

A CONVALESCENT hospital in London for Canadian officers will be opened shortly. It will have twenty-five beds. The building overlooks Putney Heath, and from its windows the patients will be able to see a memento of their own country in the shape of the Canadian flag-pole on Wimbledon Common. Another feature of special interest is North House, at one time the residence of the Marquis of Dufferin, a former Governor-General of Canada, and now occupied by the present Marquis. In the immediate neighbourhood may also be seen the home of William Pitt and of Oliver Cromwell. The new hospital has been presented to the Canadian Government by Mr. William Perkins Bull, K.C., whose residence adjoins the hospital, and who will co-operate with the Government in the management and upkeep of the institution.

Fined for Careless Diagnosis.

THE Insurance Commissioners are reported to have fined a panel doctor £10 for not taking sufficient care in diagnosing a case of consumption. In this connection the London Insurance Committee states that such fines for breaches by panel doctors are generally excessive and disproportionate, and beyond what the justice of the case requires.

Wittenberg Horrors.

A FRENCH sergeant, released from Wittenberg last February, thus records his memories of his sufferings:—

Free! from Wittenberg and its prison; free! from those long hours of bitterness and loathing. Wittenberg is now only a nightmare and an indelible memory of anguish. Wittenberg, a camp of misery where, last April, I suffered tortures from hunger which brought on two heart-attacks; where our humble parcels were pilfered and our tins of preserved food were prised open by German bayonets—I can tell this now. Wittenberg, the home of brutality, where police dogs were let loose unmuzzled among us in the barracks, where scourge and lash and knout were current change, and where the posts to which we were tied caused many an illness. Wittenberg, a camp of death, where 800 of my comrades perished either from lack of care or from cowardly rifle fire; where, on the eve of my departure, they brought in the corpse of a poor little private, only 22 years old, electrocuted in a factory where he was forced to do dangerous work, and where, with hateful cynicism, they performed the *post-mortem* before our eyes in the hospital. These are my "souvenirs" of a hellish experience now happily at an end.

Royal Institution Lectures.

At the Royal Institution on Saturday, May 6th, Professor W. H. Bragg will begin a course of lectures on "X-rays and Crystals." The Friday evening discourse on May 5, at 5.30, will be given by Sir J. Mackenzie Davidson on "Electrical Methods in Surgical Advance."

New Welsh Tuberculosis Hospital.

At Carnarvon, on April 26th, Mrs. Lloyd George opened a tuberculosis hospital of 40 beds which has been established by the King Edward Welsh National Memorial Association. Among those present were the Hon. Violet Douglas-Pennant and Dr. Meredith Richards, two of the Welsh Insurance Commissioners, and Mr. D. W. Evans, general director of the association. Mrs. Lloyd George said she looked on the tuberculosis campaign much as she did on the war. The fact that so many military huts about the country were merely of a temporary character made

her think the war would be over some day, and so, in having hospital buildings which were not too substantial she hoped we were going to overcome consumption as surely as we were going to win the war.

PASS LISTS.**Royal College of Physicians.**

At a meeting of the Royal College of Physicians of London held on April 27th, the President of the college, Dr. Frederick Taylor, occupying the chair, members of the college were elected fellows, a number of gentlemen were admitted members, and others received licences to practise physic:—

FELLOWS.—J. A. Arkwright, M.D.Camb., E. A. Cockayne, M.D.Ox., Michael G. Foster, M.D.Camb., C. E. Lakin, M.D.Lond., H. L. McKisack, M.D.Roy. Univ., Ireland, J. M. H. MacLeod, M.D.Aberd., C. H. Miller, M.D.Camb., and H. W. Wiltsnire, M.D.Camb.

MEMBERS.—A. G. Anderson, M.D.Aberd., R. Hill, M.D. Queen's Univ., Belfast, W. MacAdam, M.D. Glasg., and H. H. Scott, M.D.Lond., L.R.C.P., M.R.C.S.

LICENTIATES.—*Hannah K. Alton, K. D. Atteridge, J. Aydon, A. J. Bado, H. J. Bensted, D. S. Brachman, J. P. Bracken, I. R. R. Brogden, A. S. Carter, H. H. Castle, L. A. Célestin, G. E. Chissell, *Hester Mary Church, *Mabel Campbell Clark, A. H. Clarke, P. S. Clarke, H. M. Cohen, W. H. Coldwell, W. M. Crombie, R. C. Davenport, S. G. Dunn, F. Dunphy, M. Dwyer, W. F. Eberli, A. W. F. Edmonds, P. O. Ellison, G. I. Evans, H. S. Evans, L. W. Evans, W. Farquharson, G. Fehrsen, E. A. Fiddian, S. W. Fisk, M. R. V. Ford, A. R. Fuller, D. H. A. Galbraith, G. T. Garraway, Sures Chandra Ghose, C. C. Goodall, F. H. S. Greenish, *— Haigh, J. C. H. Harris, S. F. Harris, A. N. Haworth, N. N. Haysom, W. A. Hotson, E. G. Howell, G. P. B. Huddy, E. C. Hudgell, S. Hutchinson, T. H. Jackson, Bhopatsinhji Bhugvatsinhji Jareja, W. G. Johnston, A. M. Jones, T. Jones, V. Kameneff, Teng Liang Kan, R. P. Langford-Jones, E. E. Lightwood, C. W. B. Littlejohn, H. B. Logan, P. G. McEvedy, Showkiram Sahijram Malkani, P. S. Marshall, F. C. Mason, Adeline Mabel Matland, B. H. Mellon, H. W. L. Moesworth, T. D. Morgan, A. G. Morris, G. Moulson, Sinnethamby Muttiah, Kathira Velu Muttukumar, F. F. Newey, D. C. Norris, A. J. Orenstein, F. C. Ormerod, P. E. D. Pank, G. E. Paul, R. R. Powell, Jagan Nath Puri, H. M. Quackenbos, Raghavendra Rau Damodar, M. Schwartz, C. R. Reckitt, B. T. Rose, P. G. Russell, D. M. Smith, W. Steadman, H. G. Stormer, G. C. Swanson, D. G. C. Tasker, H. W. Taylor, G. B. Wild, R. W. Willenberg, G. C. Williams, A. Williams-Walker, C. E. Wise, R. S. Woods.

*Under the Medical Act, 1876.

The English Conjoint Board.

At a meeting of Comitia of the Royal College of Physicians of London on Thursday last, licences to practise medicine were conferred upon 99 candidates (including six ladies) who have passed the final examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board:—

Hannah K. Alton, K. D. Atterbridge, J. Aydon, B.A.Cantab, A. J. Bado, H. J. Bensted, D. S. Brachman, M.D., B.A., J. P. Brachen, I. R. R. Brogden, B.A.Cantab, A. S. Carter, L.D.S.Eng., H. H. Castle, L. A. Celestin, G. E. Chissell, Hester M. Church, Mabel C. Clarke, A. H. Clarke, P. S. Clarke, H. M. Cohen, M.D., W. H. Coldwell, W. M. Crombie, R. C. Davenport, S. G. Dunn, F. Dunphy, M. Dwyer, W. F. Eberli, B.A.Cantab, A. W. F. Edmonds, P. O. Ellison, G. L. Evans, B.A.Oxon, H. S. Evans, B.A.Cantab, L. W. Evans, W. Farquharson, G. Fehrsen, E. A. Fiddian, B.A.Cantab, S. W. Fisk, M. R. V. Ford, A. R. Fuller, D. H. A. Galbraith, G. T. Garraway, S. C. Ghose, C. C. Goodall, F. H. S. Greenish, M.A.Cantab, Ethne Haigh, M. B., B.S.

Durham, J. C. N. Harris, B.A.Cantab, S. F. Harris, A. N. Haworth, N. N. Haysom, W. A. Hotson, E. G. Howell, G. P. B. Huddy, Edith C. Hudgell, S. Hutchinson, T. H. Jackson, B. B. Jareja, W. G. Johnston, A. M. Jones, T. Jones, B.A.Cantab, V. Kameneff, Moscow, T. L. Kan, R. P. Langford-Jones, E. E. Lightwood, C. W. B. Littlejohn, H. B. Logan, P. G. McEvedy, S. S. Malkani, P. S. Marshall, F. C. Mason, Adeline M. Matland, B. H. Mellon, F.R.C.V.S., H. W. L. Molesworth, T. D. Morgan, B.A.Cantab, A. G. Morris, G. Moulson, S. Muttiah, K. V. Muttukumar, M.B., B.S.Madras, F. Newey, D. C. Norris, A. J. Orenstein, M.D., F. C. Ormerod, P. E. D. Pank, B.A.Cantab, G. E. Paul, M.B., B.S.Madras, R. R. Powell, B.A.Cantab, J. N. Puri, H. M. Quackenbos, R. R. Damodar, Madras, C. R. Reckitt, B. T. Rose, B.Sc., P. G. Russell, M. Schwartz, D. M. Smith, W. Steadman, H. G. Stormer, G. C. Swanson, H. W. Taylor, D. G. C. Tasker, B.Sc., G. B. Wild, R. W. Willenberg, L.M.S.Ceylon, A. Williams-Walker, G. C. Williams, B.A.Cantab, C. E. Wise, M.D. Lausanne, and R. S. Woods, B.A.Cantab.

The Royal College of Surgeons of Ireland.

The following candidates have passed this examination, Spring 1916:—

First Dental Examination.—Mr. Redmond J. Keating, Mr. Joseph B. McNamara Moorhead.

Final Dental Examination.—Mr. Ernest S. Brabazon, Mr. John W. Daunt, Mr. Thomas Edwards, Mr. Maddison B. Fisher, Mr. Thomas G. O'Connor, Mr. Israel Sharpe, Mr. Bernard Scher.

Primary Fellowship Examination.—Mr. James F. Seale, Mr. Alan G. Wright.

Final Fellowship Examination.—Mr. Arthur T. Thurston.

Conjoint Examinations in Ireland.

The following candidates have passed the Examination of the Royal College of Physicians and the Royal College of Surgeons, Spring 1916:—

Preliminary Examination.—Thomas Brady, Dominick J. Browne, Stephen E. Brown, Wm. H. Browne, Joseph A. B. Clarke, Dermot P. Doyle, Charles J. C. Earl, Maxey Elyan, Isaac W. Ginsburg, Charles P. Hearty, George Horkan, Lillian V. Johnston, Michael J. Kelly, Maurice Levy, Michael J. McDonnell, John D. McNery, Herbert O. Mackey, Michael J. Mallon, Mary R. Nolan, Gerald C. O'Grady, Joseph Shannon, Wm. Smyth, John Tehan, Lynda Wilkin.

First Professional Examination.—L. S. Clifford, J. L. Courtney, A. L. Dempsey, J. A. Flynn, J. E. Hudson, P. Kelly, T. J. Kerr, C. Kidd, J. F. Lyne, J. J. Lee, W. H. Mosbery, P. J. Osborne, W. P. Reynolds, T. J. Ryan.

Second Professional Examination.—M. Barden, Joseph Cockburn, B. Epstein, S. J. Halpin, B. F. Honan, J. McAleer, B. T. McMahon, R. H. Newman, J. Pousner, J. Power.

Third Professional Examination.—J. J. Brennan with honours, S. J. Healy with honours, R. J. Bassett, J. P. Brennan, J. J. Campbell, E. M. Lloyd Dodd, D. J. M. O'Flanagan, L. Finnegan, J. A. Hamilton, F. B. Harrison, J. K. Holland, D. B. McEniry, J. A. McSweeney, B. F. O'Reilly, J. C. Smyth, D. E. Young.

Final Examination.—John F. Coffey, King Elmes, Hugh Gerrard, James Magner, Charles A. R. McCay, Daniel McCormack, John A. McKinnon, Alan J. Neilan, Joseph P. Pegum, George C. L. Woodroffe.

Royal Colleges of Physicians and of Surgeons, Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.

The following is a list of candidates who passed the examinations of the Conjoint Board for Scotland:—

First Examination.—The following passed: Joseph Campbell, James Innes Coventry, Agnes Macilwraith Hill, Evan Robert Lloyd, James Charles Meek, William Muirhead Reid, Frederick James Stevenson, Marguerite Martha Isobel Swanson.

Second Examination.—The following passed: Richard Gordon Bell, Sidney Hill Waddy, Maurice Jul us Woodberg.

Third Examination.—The following passed: Robert Austin, Alexander Balfour Black, Donald M'Kenzie Black, James Calder, Jean M'Murray Crawford, Robert Phillips Crawford, John Thomas Dier, George Alexander Grandsout, Reginald Douglas Howat, Lloyd William Hughes (with distinction), Edward Glyn Jones, Joseph Michaelson.

Final Examination.—The following candidates having passed the final examination were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.: Final List—William Paterson Hay Lightbody, Glasgow; John Park Mathie, Bilston, Staffs.; John Robert Beith Robb, Glasgow; Alexander Morrison, Glasgow; Thomas Jackson, Wishaw; Andrew Smith, jun., Wickham, Co. Durham; John M'Cartney, Girvan; Ronald Harley Rattray, Melbourne; Thomas Marshall Metcalfe, Glasgow.

University of Glasgow.

At the graduation ceremony on April 25th the following degrees were conferred:—

Doctor of Medicine (M.D.).—Dagmar Florence Curjel.

Master of Surgery (Ch.M.).—Robert Buchanan Carlsaw.

Among the University prizes and special class prizes gained were the following:—

Thesis for M.D.—Matthew Young, M.D., Bellahouston Gold Medal.

Research in Anatomy.—Matthew Young, M.D., Struthers Gold Medal and Prize of £20.

Chemistry.—John B. Sandford, George Roger Muirhead, prize of £2 5s.

Laryngology and Rhinology.—Kenneth J. T. Wilson, Asher Asher Gold Medal.

Physiological Physics.—William Napier, Arnott Prize of £25.

General Physics.—William L. Templeton, Arnott Prize of £15.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE WELLCOOME HISTORICAL MEDICAL MUSEUM.

We are asked to announce that this institution will be reopened to-day (Wednesday, May 3rd). A special exhibition has been arranged in the Hall of Statuary, of Japanese charms and amulets of medical interest, which have been collected and kindly lent by W. L. Hildburgh, M.A., Ph.D. The collection is an exceptional one, especially to those interested in medical folk-lore, and visitors will be admitted on presenting their visiting card.

The museum will be open from 10 a.m. to 6 p.m. daily, and from 10 a.m. to 1 p.m. on Saturdays until further notice.

J. LAURENCE GREEN.—Your letter reached us too late for insertion in present issue; it will appear in our next.

INCREASED HOSPITAL EXPENSES.

The additional expenditure at St. Bartholomew's Hospital last year, due to the advance in the prices of provisions and fuel and to new charges, such as aircraft insurance, war bonus, allowances, etc., was roughly £9,447.

Dr. T. C. S. is thanked for the communication, for which we hope to find space in our next.

GAOL AS HEALTH RESORT.

REFUSING an application for bail, Mr. Hedderwick, at North London said: "I would recommend anybody who wishes to have a healthy holiday to go to prison for six weeks if he can get admission to a British gaol. It is much better than going to a foreign spa."

TWA OR TROIS.

TOMMY (to Jock on leave): What about the lingo? Suppose you want an egg over there what do you say?

JOCK: Ye juist say "ool."

TOMMY: But suppose you want two?

JOCK: Ye say "twa ooffs," and the silly auld fule wife gies ye three, and ye juist gie her back one. Man, it's an awful easy language.—*Punch.*

AMBULANCES AT THE FRONT.

SUPPLEMENTING the recent magnificent gift of a fleet of motor ambulances by the colliery proprietors and working miners in Nottinghamshire and Derbyshire, a motor ambulance, for which subscriptions had been obtained by the Mayoress of Nottingham, has been handed over to the Red Cross Society for use at the front.

W. S. M. (Newcastle).—The deaths registered last week from all causes were 17.2 per 1,000 of the population of your city; these were somewhat under the average, whilst the birth-rate was fortunately above the weekly average. Only one death is officially referred to as from infectious disease.

ROYAL COLLEGE OF PHYSICIANS.

SIR THOMAS BARLOW will deliver the Harveian Oration on St. Luke's Day, October 18th. In November Dr. Hector Mackenzie will deliver the Bradshaw Lecture, Dr. H. R. Dean the Horace Dobell Lecture, and Dr. W. H. Rivers the FitzPatrick Lectures.

CARITAS (Wimbledon).—For the administrative county including the City of London in the week ending 22nd April there were 1,866 births and 1,323 deaths registered. The annual death-rate from all causes, which had been 17.7, 17.9, 17.3 per 1,000 in the three weeks ended April 1, 8, and 15, fell to 16.0. Different forms of violence caused 42 deaths, all of which were the subject of coroners' inquests.

TO LEARN FROM GERMANY.

PROFESSOR SULCUMAN NUMAN PASHA, chief of the Turkish Army's Sanitary Corps, has arrived in Berlin accompanied by high military functionaries, "in order to study the sanitary institutions of the German Army."

BEE DISEASE.

MR. A. E. STONE, a beekeeper, of Tiverton, Devon, claims to have discovered a remedy for the Isle of Wight bee disease. He feeds the bees on sugar cane syrup, medicated with a solution of phenol and formaldehyde.

J. J. S. (Edinburgh).—We understand that the book is reprinting, hence the report of your bookseller is correct. As you are in immediate need of it, you would probably get a copy at a second-hand bookseller's or from Lewis's Library.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 3RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY) (1 Wimpole Street, W.).—5.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917.

ASSURANCE MEDICAL SOCIETY AND MEDICO-LEGAL SOCIETY (Conjoint Meeting) (House of the Royal Society of Medicine, 1 Wimpole Street, W.).—5.30 p.m.: Paper—Sir John Collic: The Effects of Recent Legislation upon Sickness and Accident Claims.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes):—5.30 p.m.: Prof. A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

THURSDAY, MAY 4TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Short Communication—Dr. Herbert Spencer: A Short Case of Primary Carcinoma of the Fallopian Tube. Specimens—Dr. Russell Andrews: Primary Carcinoma of the Fallopian Tube, Dr. Cuthbert Lockyer: Early Tubal Carcinoma arising in the Displaced Epithelium of Nodular Salpingitis. Papers—Dr. Henry Briggs: Unilateral Solid Primary Adenoma of the Ovary. Mr. John D. Malcolm: Second Case of Pneumo-peritoneum; Release of Gas; Recovery.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—5 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Discussion.

FRIDAY, MAY 5TH.

WEST LONDON MEDICO-SURGICAL SOCIETY (West London Hospital, Hamersmith Road, W.).—8.30 p.m.: Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of Lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes):—5.30 p.m.: Prof. A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

Vacancies.

Birmingham and Midland Eye Hospital, Church Street, Birmingham.—Resident Surgical Officer. Salary £200 per annum, with residence and board. Applications to the General Superintendent and Secretary.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North-street, Leeds.

Croydon General Hospital.—House Surgeon. Salary £200 a year, with residence, board and laundry. Applications to J. Jones, Secretary.

Northampton General Hospital.—House Surgeon. Salary £150 a year, with apartments, board, washing, and attendance. Applications to C. S. Risbee, Secretary-Superintendent.

Sheffield Royal Infirmary.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.

Victoria Hospital, Burnley.—Female House Surgeon. Salary £160 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon. Secretary, 7 Grimshaw Street, Burnley.

St. Bartholomew's Hospital, Rochester, Kent.—Senior Resident House Surgeon. Salary £300 per annum. Applications to Charles Speyer, Secretary.

Westmorland Consumption Sanatorium and Home, Meathop, Grange-over-Sands.—Second Assistant. Salary £200 per annum, with apartments, board, and laundry. Applications to C. F. Walker, M.D., B.S.Lond., D.P.H.Manch.

Dorset County Council.—Assistant Medical Officer of Health. Salary £300 per annum. Applications to Archdall Ffooks, Clerk of the County Council, County Offices, Dorchester.

Appointments.

MACKENZIE, H., M.B., Ch.B.Vict., Assistant Medical Officer of the Booth Hall Infirmary of the Manchester Union.

Births.

HANDLEY-READ.—On April 21st, (Good Friday), at 67 Brunswick Place, Hove, to Quartermaster-Serjt. Instructor (M.G.C.) E. H. Handley-Read, R.B.A., and Eva M. Handley-Read, L.D.S., L.R.C.P. and S., of Harley Place, W.—a son.

HODGES.—On April 26th, at Moorlands, Dumpton Park Drive, Broadstairs, the wife of Arthur Noel Hodges, M.B., of a daughter.

MACTIER.—On April 22nd, at St. Mary's Place, St. Andrews, the wife of W. B. MacTier, M.B., of a son.

Marriages.

BATCHELOR—KEMPTHORNE.—On April 26th, at Wyck Risington, Henry Washington Batchelor, Captain, R.A.M.C., son of the late H. T. Batchelor, of Cape Colony, to Kathleen Mary Kemphorne, younger daughter of the Rev. P. H. and Mrs. Kemphorne.

BEATTY—HANDFORD.—On April 27th, at the Parish Church, Hampstead, John Colley Pounden Beatty, Lieut., R.A.M.C., third son of the late Maj.-General R. Beatty, H.M. Indian Army, and of Mrs. Beatty, 3, Templemore Avenue, Rathgar, Dublin, to Isabella Emily Claudia, younger daughter of the late Rev. J. W. Handford and of Mrs. Handford, 14 Elierdale Road, Hampstead.

BEVEN—BREAKEY.—On April 26th, at St. Giles's, Reading, John Osmonde Beven, M.A., M.R.C.S., etc., youngest son of Mr. and Mrs. Francis Beven, of Ceylon, to Iris Marie Carew, elder daughter of Major A. J. Breakey, R.G.A., and Mrs. Breakey.

EVANS—EAMES.—On April 26th, at Twrgwyn, Bangor, Griffith Ivor Evans, Lieut., R.A.M.C., son of Mr. and Mrs. G. T. Evans, Haulfryn, Abergele, to Dilys, daughter of Mrs. Eames and the late Mr. William Eames, Moss Bank, Bangor.

GEMMELL—KELLETT.—On April 26th, at St. Mary's Church, Dalton-in-Furness, Lancashire, Captain Reginald W. Gemmell, R.A.M.C., of Upton, Cheshire, to Norah Winifred, younger daughter of the late William Kellett, J.P., of Portland Bank, Southport, and Dowdals, Dalton-in-Furness.

WILLANS—MANBY.—On April 27th, at East Rudham, Dr. Frederic Jeune Willans, of West Newton House, Sandringham, eldest son of the late Dr. W. Blundell Willans, of Much Hadham, Herts, to Wynfred, only daughter of Sir Alan and Lady Manby, of East Rudham, Norfolk.

Deaths.

CENTER.—On April 28th, at Naval Hospital, Malta, Fleet-Surgeon William Rudolf Center, of H.M.S. Russell, son of the late Surgeon-Col. William Center, I.M.S., and stepson to Mrs. Center, 7, Carlton Road, Ealing, aged 45.

GRELLET.—On April 26th, at Orford Lodge, Hitchin, Charles John Grellet, M.R.C.S., L.S.A., aged 73.

HOWES.—On April 25th, at Lincoln, Frank Charles Plumtre Howes, M.D., M.R.C.S., second son of the late Rev. T. G. F. Howes, rector of Belton, Suffolk.

ROUE.—On April 15th, William Barrett Roue, M.D., 2 Buckingham Place, Clifton, Bristol, aged 66.

WHARTON-HOOD.—On April 27th, after a short illness, at 5d, Montagu Mansions, Portman Square, Wharton Peter, M.D., elder son of the late Peter Hood, M.D., of 11, Seymour Street, Portman Square, in his 82nd year.

WOODFORD—FINDEN.—On April 27th, at a nursing home, after a long illness, Lieutenant-Colonel Woodford-Finden, Brig.-Surg., I.M.S., of 45, Portland Court, aged 71.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MAY 10, 1916.

No. 19.

AT THE PERIPHERY.

"*Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer.*"—BEAUMARCHAIS.

It is time that the medical profession began to take note of the undercurrent **The** **Medico-Political** concerning itself which is flowing strongly beneath the billows of the present absorbing and insistent distractions. **Outlook.** With our eyes and hearts intent upon the war, with added work, financial anxieties and domestic solicitude, there is scant leisure for the consideration of those questions of medical politics which at the best excite but a languid interest in the mind of the general practitioner. The attitude of nearly all previous governments towards the profession has been one of *laissez-aller*. Until the Insurance Bill was framed, legislative enactments affected portions only of the profession, medical officers of health, parish doctors, and the like, leaving the vast majority entirely untouched and for the most part completely apathetic. The coming of Mr. Lloyd George's breathless benevolence at the expense of the profession ought to have awakened us to a sense of our position as a whole; it has unfortunately done nothing of the sort. The working of the Insurance Act has certainly provoked a vast amount of individual and personal discontent, but that discontent, deep though it be, is for the most part inarticulate and therefore ineffectual. And it is inarticulate because it is unorganised.

Cave! THE absence of organisation of the medical profession is a by-word among the politicians, who see in it an opportunity for exploiting the doctors in any and every scheme which may present itself to their ingenuity. Now, it must be clearly understood that, in spite of the war, the brains of the politicians are full of new schemes which are to take effect after the war; schemes in which the doctor, according to ancient custom, is to be used while being abused, and the present absence of organisation is to be the factor which will surely place him pinioned at the foot of the vote-catching legislator. On April 25th there was a very instructive paragraph in the *Times*. It appeared at the close of an article entitled "A Health Army," in which it was suggested that the Central Medical War Committee should be utilised after the war. Here it is:—

A **Quotation.** "ONE of the weaknesses of the medical profession has been its lack of organisation. Its voice in public matters has been weak, and its counsels have often been divided.

From this cause the public and the public health have suffered. Is it too much to hope that organisation will not merely be for war purposes, but that it will lead to new conditions? The days of rigid individualism are ended. Doctors must come out into the open, and must address themselves to a world for the health of which they are responsible. They have many evils to fight—the evil of infant mortality, the milk evil, the scavenging evil, the venereal disease evil—and they will only fight these successfully when they take the public into their confidence. Meantime, the confidence of the public is largely enjoyed by quacks. Unorganised, the profession must shun publicity because of its natural and proper fear of self-advertisement, but organised it need no longer shun it. In the light the quack perishes. The time has come to defeat superstition with truth, and to enlist public sympathy for the great aims of modern medicine. Here, then, in the shape of this new medical organisation, a new opportunity presents itself."

Its **Meaning.** WITH the sentiments and reflections expressed in this quotation we must all agree. It expresses the situation admirably. But it is not very difficult to read between the lines an appeal for a re-rally to the British Medical Association, a body which is seeking to rehabilitate itself by taking credit for the more or less successful organisation of the profession for war purposes. But the profession has had enough of the British Medical Association, and not all the King's horses and all the King's men will ever put the Humpty Dumpty together again. If medical men have agreed to make the work of the Central Medical War Committee a success, they have done so in spite of the fact, and not because of the fact, that the Committee was born of the British Medical Association, which sold them for a mess of pottage over the Insurance Act. Medical men must organise; but with the Central Medical War Committee after the war, or with the

British Medical Association at any time, they must have nothing to do. The British Medical Association has blundered us into complete and ignoble impotence on more than one occasion. It must never be allowed another opportunity of so doing.

I HAVE already pointed out in these **State Medical Service.** columns that there is a strong case for the establishment of a State medical service. Such an idea is discernible in the above-quoted paragraph from the *Times*. The question is discussed whenever two or three are gathered together, and it is quite certain that as soon as the pre-occupations of the present crisis permit a move will be made in that direction. In principle, a State medical service has much to recommend it; but a thing which is excellent in principle may be altogether detestable in practice unless the details are freely negotiated and equitably arranged. Now, it is quite obvious that there can be no such thing as freedom of discussion or equity of arrangement if one of the parties is from the outset obliged to submit to any terms which the other chooses to impose. And that will be the position of the Medical Profession *vis-a-vis* the Government if the latter formulates its proposals before the profession is sufficiently well organised to present a firm and united front to proposals which it may deem unjust. The moral of this is that we must set about organising, and set about organising at once. The enemy is busily engaged upon sapping and mining operations, and unless we are prepared with a counterblast there is nothing but an inglorious and unconditional surrender before us.

Medical Women. ONE of the known subterranean manœuvres, which is being freely commented upon, is the ill-concealed endeavour to "rush" the profession by swamping it with women. The idea is, by this means, to drive a female wedge into any defensive male organisation. From what I know of women doctors, this scheme is very unlikely to succeed. Women have honourably fought for, and as honourably attained to, a position of practical equality with men inside the profession, and I think it most improbable that they will consent to jeopardise the fruits of their hard-won battles, and forfeit the recognition and respect of their male colleagues by betraying their "cloth" for a few inadequate pieces of Government silver. My own experience teaches me, on the contrary, that women doctors are exceptionally loyal colleagues, and I believe that they would eagerly join any organisation whose object was the defence of medical rights and the furtherance of medical interests. The British Medical Association has failed them, even as it has failed us. We must both look elsewhere.

The Consultant. AND what of the consultant? By setting class against class in the profession, by persistently representing the interests of the general practitioner as essentially and inevitably antagonistic to those of the consultant, the British Medical Association has done its best to

estrangle the latter, to turn him aside from anything in the nature of cohesion and combination, and unfortunately it has succeeded. This was not wilful wickedness; it was merely the bungling of breedless bounders seeking personal aggrandisement. But the result is the same. The consultant will have nothing to do with an Association which misrepresents and villifies him, which, if he should decline to conform to its suburban standards, arrogates to itself the right to brand him as guilty of unethical conduct, and which plays fast and loose with solemn pledges given in good faith. Nevertheless, the consultant must not imagine that he and his class are either above or outside the need for organisation. The schemes which are being secretly and surreptitiously hatched for nationalising and sweating the profession include drastic changes in the management and staffing not only of the large general hospitals, but of all hospitals.

The Hospitals. THESE institutions will no longer be supported by voluntary contributions; they will be financed by the State, and the State will dictate the terms on which it will be graciously pleased to accept the services of the staffs. To throw dust in the eyes of the unwary, there will be talk of payment for services which are now gratuitously rendered; the pay will, of course, be inadequate, but the accompanying conditions of service will be onerous, and the discipline summary. Are the younger consultants prepared to walk into this "bargain" with their hands tied? If not, they must bestir themselves. They must recognise that although we are fighting Prussianism abroad, there is, especially where the profession is concerned, a strong spirit of Prussianism at home, and if they are not prepared to be Prussianised, they must be ready—and able—to resist. The only way in which they can offer any effective resistance is by joining an organisation with the brains and energy to defend their interests. Such an organisation the British Medical Association is not, never was, and now never can be.

I may reasonably be asked what existing organisation there is which can be trusted to do what is necessary. To which my only reply is that I am not at present prepared with a satisfactory reply. On the principle that an empty house is better than a bad tenant, so it seems to me that it is much better that the profession should be wholly unrepresented than that its representation should be in the hands of incompetent self-satisfied noodles. To change the metaphor, a clean slate is preferable to an ill-written phrase; its very barrenness seems to invite and stimulate accurate caligraphy. It is a pity that the Panel Medico-Political Union appears so to have restricted its scope as to exclude those who are not panel doctors. There are other members of the profession who might suitably be included within the fold of its activities. If these cannot be included they ought to consider the propriety of having an organisation of their own. In any case, let them organise. **SINAPIS.**

DR. HAWKESLEY ROCHE HAYES, J.P., of Basingstoke, left £22,055.

MEDICAL ASPECTS OF THE DUBLIN RISING.

WHATEVER failings there may have been on the part of the authorities both before and during the latest Irish rebellion, the medical and nursing professions have every right to feel proud of their members who were in Dublin in Easter week. Many medical men were absent for a brief holiday when the outbreak occurred, but most of them took whatever means was in their power to return to what they considered their post of duty. As no trains were running into Dublin the journey had to be made by motor-car, or, in some cases, by relays of post-car. Most of those who were in Dublin on Easter Monday lost no time in getting to their various hospitals, where they remained without intermission or release until the following Saturday. Transit through the streets during the week was in all cases dangerous, and in many impossible. One hospital was invested by the insurgents, who kept several members of the staff as prisoners, carrying in their wounded for treatment and removing them immediately, whatever their condition. From Monday to Saturday the various medical staffs worked almost incessantly. Willing hands bore stretchers under the heaviest fire and carried the wounded—soldiers and civilians alike—into safety. Some dead were carried in—many lay unremoved for days. As our readers know, Dublin has ten general hospitals, which are scattered in all quarters of the city. This distribution of the hospitals—which has so often been regarded as a fault—proved a blessing in Easter week, since if the road to one hospital was blocked, it was usually possible to make way to another. The ten general hospitals were supplemented in their work by the King George V. Military Hospital, the Dublin Castle Red Cross Hospital, the various special hospitals which speedily provided beds and threw their doors wide, and by two Red Cross Hospitals equipped and opened with great despatch in Merrion Square and Lower Fitzwilliam Street respectively. It is impossible to suggest any estimate of the number of casualties dealt with during the week. Some two hundred and fifty dead bodies lay in the hospitals at the end of the week, and there were probably at least as many more outside. The casualties must have run into thousands. The majority both of deaths and lesser casualties was probably among harmless civilians who had the misfortune to be resident in the neighbourhood of the strongholds of the insurgents. They suffered severely from the somewhat indiscriminate military measures adopted by the authorities. Even the hospitals had their anxious moments from this cause. One suffered from several rounds of machine-gun fire, the edifice being mistaken for a neighbouring stronghold of the rebels. The workers in another hospital were alarmed at finding a big gun trained on the upper storey of the building, which was erroneously supposed to harbour a sniper. However, as far as we can learn, no medical man nor nurse was injured during the entire disturbance. It is true that ambulances were occasionally hit by bullet fire from

both sides, but this does not appear to have been intentional, and we have heard no evidence of ambulance workers being deliberately fired on. Perhaps the hottest fighting was that in the Northumberland Road area, by which the Sherwood Foresters, on the march from Kingstown, were permitted to approach the city by the only entry on the south-eastern side, which was in the hands of the rebels. The area involved is equidistant from the City of Dublin and Sir Patrick Dun's Hospitals, and these institutions had their resources thoroughly taxed. No praise is too high for the bearers, medical and lay, who exposed themselves time after time to the hottest fire in their search for the wounded. In particular, the nurses of Sir Patrick Dun's Hospital deserve special mention. When, owing to darkness, men-bearers were unrecognisable and were fired on, the nurses, time after time, ran out with stretchers and carried in the wounded. The workers in Jervis Street Hospital suffered many anxious moments, not only from the firing which for days was incessant, but from the danger of fire. The immense fire which has devastated Sackville Street—one of the finest thoroughfares in Europe—crept gradually nearer and nearer to the hospital, which was overwhelmed with showers of sparks. It was not till Saturday that the cessation of the fire gave relief to the inhabitants of the hospital. For the whole week the Royal College of Surgeons was in the hands of the insurgents. We are glad to hear that no wanton damage was done, and the building and equipment suffered little.

CURRENT TOPICS.

Shakespeare and Medicine.

THE past week has seen the celebration of St. George's day, which is also the anniversary of the birth and death of Shakespeare. On that day, 300 years ago, died "the greatest intellect who, in our recorded world, has left record of himself in the way of Literature." So writes Carlyle. In a week when universal tribute has been paid to Shakespeare's memory, on the tercentenary of his death, it was fitting that the medical profession should fall into line, and that it should be shown that the "myriad-minded man" may be classed as a master of medicine.

We welcome, therefore, the choice of orator and subject for the 141st annual oration of the Medical Society of London. Scientist and scholar, Sir St. Clair Thomson is eminently fitted to deal with such a subject as he selected for his oration on May 1st, viz., "Shakespeare and Medicine." The address displays a wealth of erudition and a felicity of expression which stamp the orator as a worthy spokesman of a liberal profession.

Sir St. Clair referred to the common-place book of the Rev. John Ward as showing that Shakespeare died of one of the low fevers prevalent at Stratford-on-Avon after a river flood, modern sanitation being unknown. He explained the poet's great grasp of medicine by his profound knowledge of life and human nature. In Shakespeare's time, medical science was but emerging from the chaos of unlicensed and irregular practice, and the marriage of his eldest daughter, Susanna, to Dr. John Hall, of Stratford, afforded his keen observation the requisite opportunity to

note the habits and ways of thought of medical men. Quacks, male and female, flourished then as now, and such practice was indeed encouraged by the fact that the regular physician was apt to cease attendance on a case he considered incurable, to save his reputation. Physic failed to minister to a mind diseased, to pluck from the memory a rooted sorrow, and to raze out the written tablets of the brain (Macbeth), and an allusion to auto-suggestion may be read into the recommendation of the patient to "minister to himself."

The works of Shakespeare contain references to ague, rheumatism, plagues, pestilence, fever, measles, "the sweat," leprosy, apoplexy, bone-ache, colic, consumption, convulsions, cramps, dropsy, ecstasy, epilepsy, gout, green sickness (chlorosis), heartburn, hemiplegia, hydrophobia, itch, jaundice, palsy, sciatica, sea-sickness, somnambulism, and visual spectra.

The poet shared the common belief that vital spirits dwell in the arteries, and that wound trouble is attributable to the access of air, an interesting observation regarding sepsis which recalls Lister's carbolic spray. His references to the circulation of the blood (in "Hamlet" and "Measure for Measure" notably) are prophetic, seeing that Harvey did not reach his famous conclusion until a week before Shakespeare's death. The social disease on which a Royal Commission has recently reported was known in Shakespeare's day variously as "the French disease," and "the Neapolitan disease." Great as was his belief in the benefits of fresh air, he still regarded night air as harmful:—

"And will he steal out of his wholesome bed

To dare the vile contagion of the night."

The passage in "Macbeth":—

"... Macduff was from his mother's womb

Untimely ripp'd."

seems to indicate the practice at that time of Cæsarean section.

Shakespeare was deeply interested in mental pathology. He shows surprising knowledge of the mental confusion preceding an epileptic attack, and of the ensuing maniacal excitement. He alludes to the value of music in sickness, but hints the influence is not always beneficial, for he states that enuresis may result from the sound of the bagpipes. We believe this is not unknown in enemy ranks when Scottish regiments get to work. And the untutored Southron says there is no music in the bagpipes! The genius of our greatest Englishman is clearly revealed in his insight into mental and nervous disorders, as witness the neurasthenia of Hamlet, the melancholy of Jaques, the coxcombry of Malvolio, the hallucinations of Macbeth, the insane ambition of Lady Macbeth, the insanity of Ophelia, the maniacal misanthropy of Timon of Athens, the blind fury of Othello, the frenzy of Constance, the mania of King Lear, and the foolish imbecility of Simple, Shallow, and Speed. In "As You Like it" we get a good idea of the way in which bad cases of madness were treated (the mild cases were not segregated):—

"Love is merely a madness, and, I tell you, deserves as well a dark house and a whip as madmen do."

In "Much Ado about Nothing" we find a foreshadowing of the principles which underlie the modern and kindly treatment of the mentally afflicted:

"Fetter strong madness in a silken thread,
Charm ache with air, and agony with words."

Mr. Stephen Coleridge will be interested in Sir St. Clair Thomson's statement that vivisection is proposed by a woman, the Queen, in "Cymbeline."

The orator concluded "The science of medicine

progresses, but human nature remains the same. Shakespeare's plays will be read by physicians when every medical treatise of the present year will have been completely eclipsed."

The address is a worthy exposition of the medical-knowledge of that master mind aptly described by the Sage of Chelsea as "an eye for us all, a Heavensent bringer of light."

Daylight Saving.

It is difficult for the ordinary man to understand the opposition which the daylight saving proposal appears to have excited in some quarters. It is, of course, obvious that an essential to the success of the scheme is that it should be universally adopted—and simultaneously. Imagination reels at the state of chaos which would ensue if these conditions were not observed. But, given their observance, the scheme seems to us not only free from disadvantages, but full of benefits. The commercial and economical aspects of the matter have been sufficiently exposed in the lay press; we are concerned here with the medical and hygienic. That daylight, especially bright sunlight, when admitted into rooms has some health-giving properties, or rather disease-preventing powers, is well known, and it is obvious that daylight saving will give a larger field to these beneficent activities. Oculists have agreed that artificial light is much more trying to the eyes than daylight, so that the "saving" proposal, if adopted, will save not only the use of electricity, gas and oil, but also the strain on the eyes of workers. Another aspect of the matter is provided by the psychical effect of working by day rather than by night. There is a sub-conscious feeling that so long as daylight lasts work should last, that when daylight fails, work should cease. Work done during daylight is therefore in most cases better done than work done by artificial light. A doctor's work is never done, but even he is human enough to prefer that his work should be done by the light of Heaven rather than by that which comes from a "main."

War Surgery in Germany.

THE second war conference of German surgeons has just been held in Berlin, the first having taken place a year ago in Brussels. The President, Prof. von Schjerning, discussing the achievements of the past year, put first the "entire disappearance" of tetanus. He was enthusiastic with regard to the results of fractures, claiming that they had established a regular treatment—we take this to mean a routine treatment—which avoided joint stiffness. He emphasised the importance of prompt medical attention, and said that especially in trench warfare German surgeons were able, even in the front line, to deal better with scalp and abdominal wounds. Life often depended on prompt surgical interference at the front. The Professor went on to repeat—what has been received with scepticism by many medical authorities—the German official statement that 86.6 per cent. of all the men treated in field hospitals, and 90.1 per cent. of all the men treated in hospitals in Germany, are able to return to service. He asserted that the death-rate is "only 1.5 per cent. of the wounded and sick." He gave the number of Army nurses as 6,800.

Flies and Refuse Heaps.

A DISCUSSION on the above subject was opened by Dr. W. H. Symons, medical officer of health, Bath, at a meeting of the Royal Sanitary Institute, held in that city on April 15th.

Dr. Symons showed how it had been proved that flies were responsible for the spreading of typhoid

fever, infantile diarrhoea, and enteritis, and said they had therefore to wage war against flies in times of peace as well as in wartime. Descriptions were given of many experiments, to ascertain the effects of chemicals in keeping down fly life. He considered there was little danger from a well-packed manure heap if it was not near milk or other food, but where manure was loosely packed and exposed to weather on the roof of a shed or in a yard, so that it might be partially freed from filth and used again in the stable, there was great danger to the public. Yet that practice was permitted in some towns, and one could see the manure so exposed as one passed along public thoroughfares.

Dr. M. Harper, medical officer of health, Bath rural district, said until the authorities gave them the power to act they could do very little in the matter. There was no order to have stable manure removed every seven days, and there ought really to be laid down some rule as to what should be done to abate that nuisance. Open dustbins should not be permitted. The treatment of garbage was defective, the mixing of liquid and dry together being harmful. Owing to shortage of labour, there was difficulty in getting refuse removed, and until incinerators were adopted he feared they would not do much to combat the fly peril.

Professor Kenwood described the anxiety of the Army Medical Advisory Board with respect to the fly peril in France and Belgium, where the system of intensive manuring was conducive to fly breeding, and said all the information available for methods of keeping flies under was collected. Touching on Dr. Symons' experiments, he said the use of borax on manure heaps probably did check fermentation, and this made the heaps unsuitable for the breeding of flies. Borax also did not destroy manurial value.

In reply, Dr. Symons said he did not think the application of borax to manure heaps checked fermentation for more than one day.

Tuberculosis in Hertfordshire.

In his annual report for 1915 the county of Herts tuberculosis officer, Dr. H. Hyslop Thompson, states that the result of the war has been to postpone the erection of the county sanatorium and hospital, and to interfere with the complete organising of the scheme for dealing with tuberculosis within the county. The dispensary system now consists of five dispensaries and nine visiting stations, and provides means for the diagnosis of the disease, for the spread of knowledge with regard to the prevention of infection, and for the treatment of early and quiescent types of the disease. One definite result of the dispensary system, with the facilities which it offers for the examination of sputum, is that cases of tuberculosis are now detected in a much earlier stage of the disease, and an increase in the proportion of early cases which come under treatment is therefore one of the first results to be obtained. The accommodation available for the sanatorium treatment of insured patients has been restricted owing to financial considerations, but notwithstanding 161 insured patients have received sanatorium treatment during 1916 some increased accommodation will in all probability be available. The postponement of the erection of the county sanatorium and hospital has called for the consideration of measures to be adopted for the provision of hospital treatment of acute and advanced cases of pulmonary tuberculosis. Such accommodation is most essential if preventive warfare against the spread of the disease is to be efficiently carried out. The County Council has

brought forward a scheme for renting and equipping a suitable house to provide accommodation for those for whom hospital treatment is most urgently required. During the continuation of the war and for some time after its termination it will be necessary to conserve efforts in connection with tuberculosis round the dispensary and tuberculosis hospital, as it is important to hold the balance equally between the requirements for treatment and the call for prophylactic measures.

Pensions for Army Nurses.

We note with satisfaction that a Royal Warrant published on May 4th with Army Orders, contains particulars of provision for members of Queen Alexandra's Imperial Military Nursing Service in the event of their being disabled during the war. A member of the service who has become disabled may be granted a pension at not less than the following annual rates:—If the earning capacity is totally destroyed, for a principal matron or matron-in-chief, £60; matron, £50; staff nurse or sister, £40; if seriously affected, the rates are respectively for the grades mentioned £50, £40, and £30; when impaired only, the rates specified are respectively £40, £30, and £20. In cases of slight impairment, a gratuity not exceeding a year's pay may be granted on retirement, while a totally disabled member who has sufficient service for pension may be granted, in addition to that pension, the following annual sum:—Staff nurse or sister, £15; matron, £20; principal matron or matron-in-chief, £25; but the pensions shall not in any case exceed the maximum pension of the rank.

PERSONAL.

DR. PERCIVAL S. HAY has been elected honorary ophthalmic surgeon to the Sheffield Royal Hospital, in succession to the late Dr. Stanley Riseley.

THE death is announced, at Chertsey, of Harriette Anne, widow of Thomas Henry Wakley, F.R.C.S., for many years editor and part proprietor of the *Lancet*.

DR. MACDONALD, the Northampton School Medical Officer, has enrolled for war service if emergency demands, and his appointment is to be kept open for him.

SIR RICHARD HAVELOCK CHARLES, M.D., F.R.C.S.I., Sergt.-Surgeon to H.M. the King and President of the Medical Board of the India Office, has, at the request of the Secretary of State for India, accepted an invitation to become Dean of the London School of Tropical Medicine.

WE learn that certain adverse rumours concerning Dr. Maurice Hayes, Hon. Secretary of the Irish Medical War Committee, were in circulation in Belfast, and probably in other parts of Ireland, last week. Dr. Hayes was spending Easter at Newcastle, Co. Down, when the rebellion broke out in Dublin. He returned to Dublin with all speed, and was engaged in the Mater Misericordiae Hospital for the rest of the week, giving attendance to the wounded. He is not related to any other Dr. Hayes in Ireland.

MR. JAMES MURRAY TULLOCH, of Otford, Kent, left £500 to the Scottish Hospital in London, to be payable on the death of his wife.

MR. ALFRED RECKLESS, of Sheffield, retired surgeon, at one time President of the Sheffield, Medico-Chirurgical Society, and House Surgeon at the Liverpool Dispensary, left £23,672.

FRENCH CLINICAL LECTURE

ON

OCULAR SYMPTOMS IN NEPHRITIS.*

By PROFESSOR F. WIDAL,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HERE is a woman, *æt.* 70, who comes to us with an interesting clinical history. This I shall describe to you in some detail, and no doubt it will strike you as simple enough, but I would remind you that not so many years since it would almost certainly have been correctly interpreted.

She is sent to us by an oculist whom she recently consulted on account of certain troubles with her eyesight. She complained of sight being "misty," as if she were peering into a fog, or, to make use of her own expression, as if she were looking through a veil. This disturbance of normal vision had been troubling her for some time, but it became more pronounced about six months ago, since which date it has steadily got worse. The oculist, on examining the fundus, saw traces of retinal hæmorrhage, and at once came to the conclusion that there must be renal disease, so he advised her to come to this hospital.

It is only a comparatively short time that we have learned to connect certain disturbances of the ocular apparatus with a constitutional disease, and the credit of having elucidated the bearings of nephritis on retinal semiology belongs in great measure to the French school. The diagnosis is based, partly on the ophthalmoscopic appearances and partly on the pathogenic division of the particular variety of nephritis.

As you are aware, it is now customary to classify cases of nephritis in three groups—(1) the hypertensive, (2) the chloridæmic, and (3) the azoturic.

Now, if you feel this patient's pulse, you cannot but be struck by its volume. By means of the Pachon sphygmomanometer, we find that the blood-pressure is 110 minimum and 280 or 300 maximum. The heart is very big, and its apex, much lowered, is found in the sixth interspace, beating strongly and forcibly, as shown by the pulsation of the thoracic wall. On percussion we find a vertical increase in the area of cardiac dulness, but no "gallop" sound on auscultation. These are all the signs of heightened blood-pressure that can be elicited.

The patient does not complain of any tingling in the limbs, though she displays some very similar phenomena. For the last two years she has suffered from cramp in the calves. Though she does not seem to get typical "dead linger," she has, however, noticed on awakening a certain numbness of the right hand, but this may conceivably be due in some measure to retraction of the palmar fascia which is present on this side.

No other signs of renal disease are present, and in particular she does not suffer from headache. It is true that she used to have sick headache when younger, but, as she says, it is now a long time since she has been troubled with anything of the nature of a headache.

We find, however, that there is some degree of pollakiuria, of frequency of micturition, most marked in the morning on getting up. She passes rather a lot of urine, probably about three pints in the twenty-four hours. The urine contains about

2.25 gm. of albumen per litre, with a few granular casts.

There are no tangible signs of chloridæmia. At most, about six years ago, did the patient notice that for two or three days her face was puffy, but it was fugitive, slight, and did not amount to much; then, too, there has been no repetition of the occurrence. Her eyelids are never puffy, nor is there any swelling of the lower limbs even when she is tired.

We may add that there is no sign of azotæmia. Her appetite is good, she is never sick, and suffers from neither somnolence nor itching. Her mental state is quite normal, she concentrates her attention on our remarks, and replies normally to questions.

We have ascertained that each litre of blood serum contains 57 centigrammes of urea. Ambard's constant is high—*e.g.*, 0.16.

Her personal history comprises an attack of measles when 20 years of age, after which she remained in good health until she reached the age of 58. Something happened at this juncture. The patient became very thirsty, and this led to her urine being analysed, whereupon it was found to contain 28 grammes of sugar per litre. At this time she was passing two litres of urine daily.

It was therefore a mild case of diabetes, to the extent of passing 60 grammes of urinary sugar in the twenty-four hours. Recent analyses, however, failed to reveal the presence of any sugar, and to-day's analysis shows merely a faint trace.

Four years ago she noticed that her sight was becoming impaired. This might be due to incipient bilateral cataract or to presbyopia. She was given spectacles, which improved matters somewhat, but for a year past her visual troubles have steadily got worse. At the present time she can barely read the newspaper—in fact, she can only make out the title. The gradual loss of visual acuity led her to consult an oculist, who found traces of retinal hæmorrhage. The patient, by the way, complains of occasional attacks of giddiness.

We find, then, in this case, certain well-marked symptoms of heightened blood-pressure, without chloridæmia or signs of azotæmia. In arriving at our prognosis, we can safely put aside the diabetic episode that dates twelve years back, when she was 58 years of age, because it only amounted to a slight, mild attack of glycosuria, such as we often meet with in elderly persons. Moreover, it seems to have altogether disappeared, since there is now not much thirst, and the test for sugar only gives a trifling reaction.

We are dealing, then, with a patient complaining of visual disturbances, which have been especially troublesome during the last six months. The disturbance consists in the fact that the patient sees objects "as through a glass darkly," and it is steadily getting worse.

She is 70 years of age, and, speaking generally, in pretty good health, though rather run down and short of breath, but she never suffers from palpitation. The heart is very forceful, but there is no galloping sound, even when the patient exerts her-

* Lecture delivered at the Hôpital Cochin.

self; no trace of œdema. There is nothing wrong in the liver or lungs.

She does not complain of feeling ill, she has a good appetite and is in good spirits. Symptomatically, the only thing that is wrong with her is failing eye-sight. The ocular symptoms consist of neuro-retinal hæmorrhages, hæmorrhagic neuro-retinitis, and this put us on the track of her albuminuria. For that matter, the patient became aware, four months ago, that her urine contained albumen, since this had been noted in the course of the analysis of the urine for diabetes. In this case the albuminuria is well tolerated since, apart from the eye trouble, the patient presents no signs of Bright's disease.

It behoves us to carry the ophthalmological examination a step farther, in order to ascertain whether she presents any white patches indicative of retinitis. That is a thing always to be looked for in such cases. When a patient presents the signs of hæmorrhagic neuro-retinitis we know that he has bright's disease, and if, in addition, we find the white patches of retinitis it is evidence of azotæmia. Hæmorrhage alone merely shows high blood-pressure.

The ocular symptoms enable us to differentiate the various forms of nephritis, hypertension, azotæmia, and also chloridæmia. This is the rarest, but it is sometimes met with. I recently saw such a case in a lad suffering from acute nephritis. The eye is congestive, œdematous.

It may not be without interest to remark that hypertensive nephritis, which gives rise to retinal hæmorrhage, is often associated with other hæmorrhages, such as epistaxis and cerebral hæmorrhage. Chloridæmia, which can be recognised in the fundus by œdema of the papilla, also causes œdema in other parts of the body.

In such a case as this we must look for albumen, but this is not all. We must examine the patient from the threefold point of view—chloridæmia, hypertension, and azotæmia. Inasmuch, however, as this patient has never had œdema in any part of the body, we can dismiss the question of chloride retention. Nor does she seem to have presented any of the signs of hypertension, except, perhaps, a tendency to cramp in the calves. We have, however, only to feel her pulse to be made aware that it is in very pronounced hypertension. As a matter of fact, Pachon's instrument gives 300 mm. maximum and 110 mm. minimum. You see then that there is a tremendous difference between the minimum and the maximum, just as there is in aortic subjects. This hypertension alone would explain the retinal hæmorrhage, but as there is a suspicion of white patches of retinitis we must also look for azotæmia.

She does not present any functional disturbances which would lead us to suspect azotæmia; the appetite is good and her mind is quite clear. But we find that she has 0.56 gm. of urea per litre of blood serum, and when we obtain this result at a first examination, it should lead us to make further observations in order to find out whether the mischief is progressive. Ambard's constant is not always or necessarily of much significance. It possesses particular interest to us precisely when the proportion of urea is only slightly above the normal. When this is the case, the constant is enough to decide the question in one or the other direction. In the case under consideration this constant is very high, so that it points to azotæmia.

But the result of ocular examination must confirm that arrived at by chemical means. The fundus may afford convincing evidence of incipient azotæmia as yet only producing uncertain chemical changes.

When a subject of Bright's disease only has from 0.57 to 0.60 centigrammes of urea per litre of serum this may be taken to indicate commencing azotæmia. Whether it is going to be progressive, culminating, in three or four months, in major azotæmia, is a question that can only be answered by repeated examinations of the blood.

When we find white patches of retinitis, even should there be not more than 0.57 centigrammes of urea per litre of serum, we are in a position to assert that the patient is azotæmic and that the azotæmia is likely to prove progressive.

It is of the greatest interest to know this relationship between azotæmia and retinitis. Not only may we meet with retinitis in pronounced cases of azotæmia with 3 or 4 grammes of urea, which mark the terminal phase, and in less marked cases in which we get 1 or 2 grammes, but even in incipient cases of azotæmia.

So far, this interpretation of the significance of azotæmia has never been belied. Retinitis is the symptom which betrays the certain advent of progressive azoturia at a stage when it may be practically impossible to obtain any chemical evidence of its presence.

If we only get retinal hæmorrhage, then no conclusion can be arrived at in respect of the azoturia, because the very marked hypertension displayed by this patient of ours *per se* suffices to explain much. The prognosis depends entirely on the result of examination of the fundus of the eye.

The physician cannot be of service to his patient, or hope to formulate a trustworthy prognosis unless he be familiar with the valuable information to be drawn from examination of the eye in Bright's disease. This statement is borne out by the case before us, for the woman presents no flagrant symptoms: œdema or pronounced visceral disturbances; in fact, she is leading her ordinary life, and only came to consult on account of a veil before her eyes. To ascertain whether her state is due purely to hypertension, or to azotæmia as well, no evidence is more convincing than that drawn from examination of the fundus, because chemical examination does not enable us to say whether or not she is the subject of progressive azotæmia. Confirming, as it does, the results of chemical examination, the ocular examination enables us to conclude that it is a case of commencing progressive azotæmia, and this even had no examination of the blood been made.

As for treatment, we shall apply the usual treatment for hypertension:—

Nitrate of soda 1 gramme.

Spirit of lemon 2 grammes.

Water 3 grammes.

Simple syrup 100 grammes.

A teaspoonful night and morning for ten days.

At the same time lactate of strontium 2 grammes a day, to control the albuminuria, and in presence of white patches of retinitis give 20 drops of tincture of squill daily during the ten days following the administration of nitrate of soda.

WILLESDEN Guardians have refused to grant a licence for a home for babies to be fed on milk from goats kept on the premises.

MR. HENRY SMAIL, of Donhead Lodge, Wimbledon, left £1,000 each to the Wimbledon Hospital and the Nelson Hospital.

DR. HERBERT WILLIAMS, Medical Officer of the Port of London, left £7,363.

THERE are four British Red Cross units in different sections of the Italian lines.

ORIGINAL PAPERS.

THE TREATMENT OF BACKWARD DISPLACEMENTS OF THE UTERUS.*

By FREDERICK J. McCANN, M.D. EDIN.,
F.R.C.S. ENG.

Surgeon to the Samaritan Free Hospital for Women,
London, N.W.

INTRODUCTION.

DISCIPLES of the Healing Art are not infrequently taunted by the laity that their treatment of common ailments is far from satisfactory.

That this is true to a certain extent cannot be gainsaid, for what is of common and everyday occurrence seems not to stimulate the ardour of the scientific investigator who looks further afield to discover amidst the rarer morbid processes some fruitful source of enquiry. There is a tendency, too, in clinical work, to spend more time and thought over what are termed "interesting cases," and to treat common ailments on a routine plan. Yet such ailments are all important to the patients, the more so because of their frequent occurrence.

Backward displacement of the uterus is a common ailment which, from its frequency and importance, demands the closest investigation and study in order to decide what measures of relief may be afforded to the unfortunate sufferer.

Happily, the treatment has markedly improved in recent years owing largely to the advances made in gynæcological surgery, and to a better understanding of the causation and sequelæ—so that women can now be promised a restoration to health, which was not attainable in former years.

When a backward displacement is discovered it is necessary to determine the cause, for this often affords important guidance to correct treatment.

CONGENITAL DISPLACEMENT.

The displacement may be congenital, for it has been discovered in the newly-born.

I have found undersized retroflexed uteri not infrequently amongst Polish Jewesses of the hospital class, who seek treatment for sterility, and in whom there were no symptoms pointing to any uterine trouble.

The association of under-development of the uterus, antelection, dysmenorrhœa and sterility is well known, but I have rarely found small-sized retroflexed uteri amongst British women. Such examples represent the true congenital backward displacement, and although fully developed uteri, displaced backwards may be found in young girls, it is more than probable that the displacement is acquired. In another type met with in the newly-born the cervix is much elongated, the uterine body small and the organ is retroverted; and in yet another type the uterus is retroverted and antelected. Needless to say, unless symptoms result, no treatment is indicated.

EXCESSIVE UTERINE MOBILITY.

Again, excessive mobility of the uterus may be encountered, so that it may at one examination be found displaced backwards and at another occupying an anterior position.

TRAUMATIC DISPLACEMENT.

The part played by traumatism in the production of backward displacement has been variously estimated from time to time, but from a close study of this subject I have come to the conclusion that in the causation of backward displacements in virgins and nulliparæ and in parous women, too,

the possibility of traumatism as an ætiological factor must constantly be borne in mind.

I have seen backward displacement of the uterus result from accidents in the hunting field, falls on the buttocks, strenuous exercises at school, and recently after strenuous "war work."

When the extreme mobility of the normal uterus is remembered it is indeed surprising that this accident does not happen more frequently. Yet it is stated to be very rare and has even escaped mention by many writers.

The acute displacement is an example of a true intraperitoneal hernia in which the body of the uterus becomes incarcerated in the pouch of Douglas.

The symptoms suggesting the possibility of an acute traumatic backward displacement may be thus briefly summarised.

Pain is referred to the lower sacral region and coccyx. If the woman attempt to stand there is slight nausea and vague distress in the epigastrium. Pain is often localised over the sacro-iliac synchondrosis or down the sciatic nerve. Defæcation may be painful, and headache, generally occipital in type, may be a prominent symptom. Added to these there may be distressing vesical irritability whilst the menstrual type becomes altered. Uterine hæmorrhage may follow the accident or menstruation becomes painful, prolonged and too frequent. Amenorrhœa has been noted. If treated promptly there is no change in the menstruation. There is a characteristic posture and gait like traumatic lumbago. The shoulders are stooped forwards, the head carried slightly forwards, the dorsal and lumbar portions of the spinal column being held in a position of slight kyphosis.

The treatment consists in replacing the uterus under anæsthesia followed by rest in bed for at least a fortnight.

The majority of backward displacements in virgins and nulliparæ are, however, encountered in what may be termed the chronic stage.

TREATMENT OF BACKWARD DISPLACEMENTS IN VIRGINS.

When symptoms suggesting some pelvic disorder are met with in a virgin a recto-abdominal examination, preferably under anæsthesia, should be made. If a backward displacement be discovered it is necessary to determine whether the displacement alone is the cause of the symptoms. A careful abdominal examination should be made to make sure that there is no visceral ptosis (stomach, intestine or kidney) at the same time noting the condition of the abdominal wall and the general muscular development.

If the woman be of the thin neurotic type exhibiting various so-called reflex nervous phenomena, pains of various kinds, fatigue after slight exertion, gastric troubles, and constipation with feeble muscular development and visceral ptosis, the uterine trouble is only a small part of her disease and treatment by pessary or operation will do little good.

For such women local treatment should be avoided and massage, exercises, fresh air and appropriate employment will be most helpful.

For those in whom the displacement is not associated with visceral ptosis I believe surgical treatment affords the greatest relief.

It is often urged that the woman should be told to forget about her displacement, or if it is not causing marked symptoms, it should be left alone, or if discovered accidentally the knowledge should be withheld from her, or, again, she may be told she is neurotic and fanciful, when her sufferings are very real. Indeed, much depends on the attitude the medical attendant adopts when confronted with disorders of this kind.

* A paper read before the Harveian Society, April 13, 1916.

That a backward displacement of the uterus has a profound influence on a woman's health and well-being is evident from the extraordinary benefit which follows its cure by operation. And although in my earlier days I approached this subject with a sceptical mind, I am now convinced of the far-reaching effects produced by a backward displacement, and can fully credit the importance given to this subject by our medical forefathers.

Further, it is frequently advised that nothing should be done if symptoms are absent. To this I reply that sooner or later a backward displacement will cause symptoms, and that as a spontaneous cure is not to be expected, the sooner the displacement is remedied the better for the patient.

Apart from prevention, the trend of all modern treatment is to apply the remedy in the early stages of disease in order that the malady may be effectually checked. The same principle should therefore be applied in the treatment of backward displacements.

The modern gynæcological surgeon has had the great advantage of being able to inspect the pelvic organs through an abdominal incision and so obtain a knowledge of living pathology which was denied to his forefathers, who relied solely on clinical or *post-mortem* evidence.

From actual inspection on the operating table I have satisfied myself of the frequency with which tubal inflammation accompanies a chronic backward displacement, how the appendages become congested and adhere to neighbouring bowel or pelvic peritoneum, and how the uterine body becomes enlarged and congested.

It is assumed by some writers that the uterine congestion is due to the body of the uterus being gripped by the peritoneal folds bounding Douglas' pouch. I have paid some attention to this subject by observing the actual conditions when the abdomen was opened. I have seen the uterine body deeply congested, dark, purple in colour, on many occasions lying perfectly free from the folds of Douglas, and also uteri whose colour closely resembled the normal being "gripped" by these folds. Moreover, these folds are easily stretched, and the distance between them varies considerably in different individuals whilst child-bearing exerts an important influence.

I believe the uterine congestion is due to the torsion of the broad ligaments tending to retard the venous return, and that where this congestion is only slight in amount, the torsion is not so marked and the circulation better able to accommodate itself to the altered conditions. Needless to say, when the uterus is infected another factor comes into play.

Slow and insidious changes occur in the uterus and appendages, which sooner or later will cause symptoms both local and general.

For all these reasons a backward displacement should not be left alone, but should be promptly remedied.

In a virgin it is much better to remedy the displacement by an operation than to introduce a pessary. It is surely better for her to have a neat abdominal scar than a torn hymen and a stretched septic vagina.

TREATMENT OF BACKWARD DISPLACEMENTS IN NULLIPARÆ.

In the nulliparous married woman the problem is a little different, for should she become pregnant this may lead to the cure of her displacement. Unfortunately, however, although pregnancy may occasionally occur in a uterus displaced backwards, as a rule the displacement hinders conception, and for this reason the woman may present herself for examination.

When an examination is made and a backward displacement is discovered, then the mobility of the uterus should be tested.

Can it be replaced into the normal position, or is it fixed?

A useful clinical division of backward displacements is into three classes:—

1. Those in which the uterus is replaceable without anæsthesia.

2. Those in which the uterus is replaceable with anæsthesia.

3. Those in which the uterus is fixed.

The uterus may be movable to a certain extent without being replaceable in its normal position. Such movement is permitted when the adhesions are not numerous and are filamentous in character. Again, the woman may resent any attempt at moving the uterus owing to the tenderness of the uterine body or the prolapsed appendages. Such uteri are readily replaced under anæsthesia. If, in addition to tenderness, the adhesions are numerous and strong, the uterus remains fixed even under anæsthesia.

To determine if the uterus be replaceable is the first step in treatment. If replaceable, treatment by pessary may be tried, whilst if the uterus be fixed a pessary will cause pain through pressure on inflamed or sensitive structures.

METHOD OF REPLACING THE UTERUS.

(a) *Bi-manual Replacement.* The uterus may be replaced by the internal fingers pressing the fundus upwards and forwards until it is further assisted by the external hand, the internal fingers being then used to press the cervix backwards and upwards.

(b) *Replacement by the Aid of the Vulsellum.* Where there is difficulty in carrying out bi-manual replacement the anterior lip of the cervix should be seized with a vulsellum and the uterus pulled downwards and then the cervix pushed upwards and backwards thus causing the fundus to rotate forwards. As a rule, this alone will suffice, but if there be any difficulty the finger or fingers may be used in addition, to push the fundus forwards.

(c) *Replacement by the uterine sound.* The usual method recommended is replacement by means of the uterine sound. With the sound you may infect the uterine cavity, you may perforate the fundus, or you may produce abortion in a gravid uterus. For all these reasons the sound should be avoided. Nothing can be more reprehensible than the repeated straightening of the uterus by means of the uterine sound, for the risks of infection are very real and tubal inflammation may follow.

TREATMENT BY PESSARY.

Having replaced the uterus, it is maintained in position by a pessary. The capacity of the vagina will have been gauged by the former examination and a pessary of suitable size should be selected or a cast of the upper portion of the vagina may be taken by means of a thin rubber ring previously immersed in boiling lotion to make it soft, and a pessary of corresponding size can be procured, or, if necessary, made.

The most suitable variety of pessary is the Hodge or Albert-Smith, made of hard glass or vulcanite. It should be introduced in the antero-posterior diameter of the vulva, the index finger pressing the upper bar backwards and upwards into the posterior fornix. The pessary should be grasped by the vaginal vault and should not cause pain or discomfort. Before leaving the examination couch the woman should be asked to "bear down,"

in order to see whether or not the pessary can be pressed out.

It is well to request her to report herself in three or four days to ascertain if the pessary is causing any pain or interference with micturition or defæcation.

During the wearing of a pessary a daily vaginal douche is necessary, and for this purpose warm saline solution is useful as it does not interfere with conception.

The pessary should be changed every two or three months when the opportunity may be taken to see if its use may be discontinued or if a smaller or larger size be required.

When asked the question, "How long has the pessary to be worn?" the answer is until the uterus can maintain itself in the normal position. That may be months or years, or it may never maintain itself in the normal position.

Women are often told that they will be cured at the "change of life." This is true when the uterus becomes smaller and the upper portion of the vagina contracts, or when, from an increased deposit of fat, the retentive power of the abdomen is increased. But in parous women with a relaxed vagina and a gaping vulva the condition becomes worse.

I think, therefore, that the prospects of pessary treatment should be put before the patient and let her decide whether she will endure the inconvenience of wearing a pessary or have surgical treatment.

A vaginal pessary is an unclean thing, requiring constant attention, and as it acts by stretching the vaginal vault, it is in reality favouring the condition it is supposed to remedy, and as cures by pessary treatment are not numerous, I believe the interests of the patient are best served by advising appropriate surgical treatment. Moreover, the social status is an important factor, for the hard-worked woman has not the time to give the attention and care which treatment by pessary demands.

The uterus may be found tilted slightly backwards in association with a congenital hypertrophic elongation of the cervix, a condition frequently mistaken in practice for a uterine prolapse. A supra-vaginal amputation of the cervix followed by accurate suture cures the condition and successful pregnancy has followed this operation. When met with in a virgin the same treatment is employed.

TREATMENT OF BACKWARD DISPLACEMENT WHEN PAIN AND TENDERNESS EXIST.

When the body of the uterus is tender and any movement of it is resented, before attempts at replacement are made, treatment should be applied. The best is the "Ichthyol treatment."

For its successful application, the patient should rest in bed for a fortnight or three weeks during which time tampons of glycerine and ichthyol 10 per cent. are inserted into the vagina every other day and a saline douche given once a week to clear away the excess of ichthyol. Ichthyol vaseline 10 per cent. is rubbed into the flanks, and ichthyol pills 2-3 grs. given three times daily. It will be found that after this treatment the uterus can be easily replaced and a pessary inserted.

When the uterus is enlarged and there is excessive and irregular menstruation, probably indicating that there is some adenomatous growth in utero, the curette should be employed to remove this growth under anæsthesia, and after all discharge has subsided a pessary may be inserted.

It is here that the operation of curetting may be usefully employed, but only if the menstrual loss is markedly increased, as it is an operation whose indications are very definitely limited, and it is far too frequently done at the present time.

From a series of cases collected by the late Dr. Herman, he estimated that in 40 per cent. menstruation was increased, sometimes in quantity, sometimes in frequency, sometimes in both. Occasionally it is diminished. What is frequently noted is a "relative retention" of the menstrual flow so that it is prolonged as a brownish discharge for two or three days, and in the intervals between menstruation a uterine discharge mucoid or mucopurulent comes away in gushes.

All these symptoms disappear when the uterus is kept in position and no curetting is required. They prove, however, the evil effects which result from a backward displacement.

The wearing of a pessary is only a part of the treatment of women with backward displacements, and general treatment should always be adopted. For this purpose tonics, exercise in the fresh air, graduated exercises, massage and dieting are most helpful. The appropriate exercises should be written down and carried out by the masseuse under medical supervision.

The somewhat narrow outlook possessed by many of those who attempt to treat these disorders in women has been the means of diverting countless numbers of patients into the hands of various types of unqualified practitioners. Many patients seem to take a delight in informing medical practitioners that they have tried many doctors, without obtaining any benefit, and that they have been cured by massage and exercises. It behoves us all to take the hint and "set our house in order," and remember that to strengthen the abdominal muscles and to favour the deposition of fat is the best way of increasing the retentive power of the abdomen.

THE TREATMENT OF FIXED BACKWARD DISPLACEMENTS IN NULLIPARÆ.

The fixation of the uterus is produced in the great majority of instances by adhesion of the appendages, although the uterus itself may also be bound down. It follows, therefore, that the position of the uterus is secondary to some infective inflammatory process spreading from the uterus and appendages to the pelvic peritoneum or spreading from the bowel.

The primary purpose of treatment must therefore be to deal with the effects produced by the pelvic inflammation.

Where there is a history of previous attacks of pelvic peritonitis with pain and fever, and on examination, a fixed mass, or fixed masses, found behind the uterus, it is suggestive of the presence of pus, and operation is imperative.

In the more chronic or sub-acute infections, pus may not be present, or if it is, the amount is small, and for these palliative treatment by tampons, douches, counter-irritation, etc., is usually recommended.

Here, again, I believe the interest of the patients is best served by an early resort to surgical treatment conducted on conservative lines. Delay means destruction of the value of the Fallopian tube as a channel for the passage of ova or spermatozoa and insidious and destructive changes in the ovaries. To speak of cure by medical treatment is only to fog the vision, for the so-called cure means too often the destruction of the fertility of the individual, the destruction of the function of the tubes and ovaries. Moreover, if surgical treatment be too long delayed a secondary infection from the bowel is not uncommon, which may be so severe as to necessitate for its eradication the removal of the greater part of the genital organs. The policy of "wait and see" should be abandoned, and that of "look and see" adopted.

(To be concluded in our next.)

THE DIFFERENTIAL DIAGNOSIS OF MILD THYROID TOXÆMIA AND INCIPIENT PULMONARY TUBERCULOSIS.*

BY C. G. JENNINGS, M.D.

Detroit.

CERTAIN cases of mild thyroid toxæmia with cough and chronic pyrexia bear so close a resemblance to incipient pulmonary tuberculosis that a differential diagnosis may require a very close analysis of all the clinical and laboratory findings. Writers generally have not given attention to this subject. In the presence of the physical signs of an active lesion in the lungs, with or without tubercle bacilli in the sputum, the question of diagnosis between tuberculosis and mild thyrotoxicosis would not arise. Nor would it arise, on the other hand, in a case with well-defined thyroid hypertrophy, tremor, tachycardia and nervous irritability without physical findings in the lungs.

An early, small, central focus of infection may fail to yield signs that to the average physician are sufficient to justify a positive diagnosis of tuberculosis. The X-ray may help, but will not differentiate between an old and an active process, and a positive tuberculin reaction is not always convincing. A negative sputum finding is frequent. Such cases, with the results of physical examination uncertain, and showing constitutional symptoms suggestive of both early tuberculosis and thyroid disease, may give great difficulty in diagnosis. To differentiate the two conditions will demand a thorough familiarity with all the minor clinical distinctions.

It is foreign to the object of this paper to discuss the pathology of these cases of mild thyroidism. It is enough to say that they cannot be classed either as incipient myxedema or incipient Graves's disease. They appear to be cases of perverted thyroid function, the exact nature of which has not yet been determined. From strictly clinical studies I have thought that this disturbance is primarily a fatigue sub-activity of the gland, followed by a compensating hyperactivity with the elaboration of a toxic secretion. The recently published "Pathological and Clinical Studies," by Wilson and Plummer, show that such a toxic goitre, distinct from exophthalmic goitre, is a pathological and clinical entity. Further, the symptoms of this disturbed function respond to treatment by mental and physical rest, and by the administration of a suitable thyroid preparation.

Mild cases of thyro-toxicosis are seen chiefly in women at two periods of life; in early adolescence and between the ages of 40 and 50. Several cases have come under my observation in young men of neurotic type who have been subjected to prolonged mental over-fatigue, or who have been reduced by acute infections or surgical operations.

For discussion of the differential diagnosis the symptoms of the two conditions naturally fall into three groups.

(1) The symptoms distinctive of thyroid toxæmia: (a) Enlargement of the thyroid gland, (b) tremor, (c) vaso-motor phenomena, (d) insomnia, (e) nervous irritability.

Inspection and palpation of the thyroid gland is a part of the routine of every complete physical examination. Enlargement of the gland would immediately suggest further inquiry for thyroid symptoms. This may, however, early in the disease, be slight or absent, and the examiner thus led astray. Tremor may not be marked and, unless

sought for, is apt to escape detection; when noted it gives a clue to the nature of the trouble. It is not present in tuberculosis, and it is one of the most important symptoms differentiating the two diseases. Vaso-motor ataxia causing patchy blushing of the face and neck is a suggestive symptom, and not present in tuberculosis. Insomnia and nervous irritability are not often seen in early tuberculosis, but are frequent and distressing symptoms of thyroid disturbance. Not rarely they are the symptoms for which the patient first seeks relief.

(2) The symptoms and signs distinctive of pulmonary tuberculosis: (a) Tubercle bacilli in the sputum, (b) physical signs of an active pulmonary lesion, (c) the X-ray findings, (d) the tuberculin reaction, (e) loss of weight. The first four of this group need no detailed consideration; they are always sought for and, when found, fix the diagnosis. Loss of weight, however, is an important symptom, as it is not often seen in the mild thyroid cases we are discussing: in fact, these patients with their restricted activities often gain in weight.

(3) The symptoms common to both conditions: (a) Debility, (b) tachycardia, (c) pyrexia, (d) cough and dyspnoea, (e) derangement of digestion and metabolism.

Debility, or the more expressive term fatigability, is an almost constant symptom in both conditions under discussion, and is the one that often first attracts attention to the illness.

Thyroid fatigability is apt to be more pronounced than the loss of strength of tuberculosis, and is more distinctly a nervous symptom. It is easily excited by mental exertion or by emotion. It often shows itself in an uncertainty in walking or an unsteadiness in rising from a sitting posture. It seems to be the symptom that is back of the apprehension these patients often have on the street or in crowded cars. Another distinction of great significance is, that the loss of strength in thyroid toxæmia is not attended, as noted above, by loss of weight. In two recent cases under my observation, when I have strongly suspected an early tuberculosis, the fact that the patients did not lose weight first put me on the track of thyroid disease.

Acceleration of the pulse to 100 or 110, accompanied or not by a mild pyrexia, is a symptom of the greatest significance in the diagnosis of tuberculosis.

Thyroid toxæmia practically always shows a similar tachycardia. Thyroid tachycardia is, however, erratic. Trifling emotional disturbances excite and increase it. The rate will vary twenty beats or more in a brief period of observation. The wave is small and jerky, and the blood-pressure often elevated. The pulse of tuberculosis is steadily above normal, maintains a uniform rate under observation, and the blood-pressure is usually low. In thyroid disease the rapid heart tends to be turbulent in its action. The patient is conscious of the condition, and is distressed by it. In other words, there is palpitation.

Mild chronic pyrexia is one of the most characteristic symptoms of early pulmonary tuberculosis. Of this symptom Hawes, of Boston, says: "Combined with a loss of weight and strength and other suspicious constitutional symptoms, a slight afternoon fever up to 99.2° or 99.4°F., or a constantly subnormal temperature with rapid pulse, may be considered an almost positive symptom of tuberculosis, whether or not definite signs are found in the lungs." This expresses the general medical opinion of the importance of this symptom.

* From *Transactions of the American Climatological Association*, Vol. XXX.

A pyrexia almost identical in its course is met with in many cases of mild thyroid toxæmia. I have been unable to determine to my satisfaction any well-defined distinctions that can be made in this symptom in the two conditions. The range is about the same and the diurnal variations are very similar. Perhaps, the early morning subnormal temperature so frequent in tuberculosis is not often in evidence in the thyroid pyrexia.

Pathological conditions of the upper respiratory tract are noted with great frequency in thyroid toxæmia. Hypertrophied and infected tonsils are found to be present in about 30 per cent. of the cases and it is not improbable that absorption from chronically infected tonsils is an important ætiological factor in thyroid toxæmia. An associated pharyngeal and laryngeal catarrh usually is present, and chronic cough is a frequent result. There is very little to distinguish this cough from that of incipient tuberculosis. It may, however, be paroxysmal in character, or plainly due to excessive pharyngeal secretion.

Disturbances of digestion and assimilation require but a word. They are frequently observed in both conditions. The relation of a persistent indigestion to an incipient tuberculosis is well recognised, and when accompanied by debility, rapid pulse, and fever, always arouses suspicion of infection. There is nothing distinctive, however, in the character of either a tuberculous or a thyroid dyspepsia.

FOLK CURES BY CONSTRICTION AND RINGS, WITH A DIGRESSION INTO THE NATURE OF THE SOUL.*

By DAN MCKENZIE, M.D.

ONE of the fascinations in the study of folk-medicine consists in ferreting out the primitive medical practices which passed into orthodox medicine to linger on, some of them, even as late almost as our own days.

Some of these practices are discernible in the constriction cures so common in primitive and ancient medicine, an example of which is still prevalent in England in the popular practice of tying a tight garter round the leg to prevent cramp. In addition to constriction cures proper, we may also take this opportunity of referring to band and ring cures, like the anti-rheumatic finger-ring, which is still obtainable for one shilling at any chemist's.

At first sight, cures like these seem as if they had originated simply in charms, and there can be no doubt that some of them did actually begin in this way. But a closer acquaintance shows us that many of them have a much more complex and interesting origin than that. Of course, as in other departments of folk-medicine, the idea of the charm or amulet is met with even in this group also, but it is not, as I hope to be able to show, the sole origin of the custom.

To begin with the ligature remedy for pain, as in the garter cure for cramp. Here, it is obvious, we are dealing with what, in the first instance, is a simple and rational practice, seeing that pressure and constriction do actually relieve pain. And instances of ligature cures of this kind are plentifully to hand from all countries, savage and civilised. For example, in Sumatra, as Bartels points out, as well as in Western Europe, a band or cloth twisted round the head is a common cure for headache.

In addition to this simple and rational type, however, there are others of which the meaning is not so readily apparent.

First of all, still keeping to the purely physical varieties, there is the large group in which a constriction is applied with the definite object of forcibly restraining growth in bulk, and of these the best-known is the obstetric binder or girdle of pregnancy.

The girdle of pregnancy has an extensive distribution both in time and in space.

As is well known, the women of ancient Greece and Rome were in the habit of wearing a body belt or girdle during pregnancy, and the same is true of the women of Phœnicia, for the symbol of Astarte was a girdle. Assumed at the eighth month of gestation, and worn until parturition, it was then laid aside, for which reason one of the attributes of Artemis (*a*) in Greece and of the Roman Diana was "the girdle-loosener" (*Solvizona*). In later times the custom met with criticism, however, particularly from Soranus of Ephesus (A.D. 100), who recommended that it should be worn only up to the eighth month and then discarded, in order, as he said, that the weight of the child might aid in bringing on labour at the proper time.

The obstetric girdle was in universal vogue in Europe at one time. Mention is made of it in France in the days of Ambroise Paré, and we are still reminded of it in the French word *enceinte*, as well as in the German word *Entbindung*, which shows that the ancient Germans, like the Greeks and Romans, laid the girdle aside at the onset of labour. Naturally enough, the girdle came to bear a mystic or semi-sacred character, or it had that quality added to it. Thus, in mediæval England the girdle of Abbot Robert of Newminster had the power of ensuring that women who wore it would have an easy confinement.

The Ossianic poems allude to a girdle which had similar properties, and there are said to have been in the North of Scotland obstetric girdles inscribed with mysterious figures which were preserved as heirlooms in certain of the old families. I do not know whether the girdle still lingers on in that part of the country, but in the Lowlands of Scotland and in England the practice seems to have died out.

In France, however, we hear of mystic girdles as being in use as recently as 1886. The sisters of St. Ursula, of Quintin, Côtes du Nord,

"own one of the chief educational seminaries in Brittany. And when a young lady whom they have educated gets married and is about to become a mother the pious sisters send her a riband made of white silk, decorated by the clever brush of the best calligraphist in the community with a beautiful inscription in blue letters. Before sending it off the sisters bring it carefully into contact with the reliquary in the parish church, in which is preserved a precious fragment of the very binder which the Holy Virgin herself wore, as a number of unimpeachable parchments clearly certify. The inscription in blue letters on the riband reads:—'*Notre Dame de Délivrance, protégez-nous!*' The young lady who receives the blessed riband is instructed to put it around her body in order that her accouchement may terminate happily."

Turning now to extra-European countries, we find the girdle in common use there also. That of Japan deserves a special mention. The first we hear of it is, strange to say, in an account of a Japanese Embassy to Rome (probably a fruit of the early Jesuit mission to that country by St. Francis Xavier) as far back as A.D. 1586, by a certain Guido Guetleri, a Venetian.

"As long as they are not pregnant," he writes, "the binder worn by Japanese women is large and easy, but as soon as they perceive that they are gravid they tighten up this bandage so forcibly with a string that one would almost expect them to burst. 'And

* Read at the History of Medicine Section of the Royal Society of Medicine.

(a) The Athenian women at their first confinement dedicated the girdle they had worn to Artemis, placing it in her temple.

yet,' they say, 'we know by experience that if we do not do so we have to endure a very severe labour.'"

The Japanese binder was strongly condemned by the reformer Kangawa, from whom we learn that it can be traced back in the historical records to about A.D. 1180. As a result of Kangawa's sensible opposition, the obstetric binder in Japan has now fallen into comparative desuetude.

The girdle is worn in China. And in Burma, as in ancient Rome, a tight bandage is applied at the beginning of the eighth month in order to prevent the womb rising, since the Burmese woman believes that the higher the child rises, the longer and more difficult will be the labour. Similar practices are reported as being prevalent among the women of Macassar, Celebes, Java, and Malacca, and also among the squaws of the Chippeway Indians.

Thus the origin of the girdle of pregnancy seems to lie, as we see from the more primitive instances, in the hope of preventing, by sheer physical force, the fœtus from reaching a size so great as to impede labour. Magical restraint does not seem to be thought of in any of the instances I have so far encountered, but that a religious, as distinct from a magical, modification of the custom comes into play is no more than one would expect. Popular customs such as this was always do take on a religious cast after a time.

Every modern medical practitioner is of course acquainted with the "binder" which is applied after the child is born, in which respect it differs from the ancient girdle of pregnancy. In spite of this difference, however, it is not unreasonable to suppose that the puerperal binder of modern obstetrics may be the lineal descendant of the girdle of pregnancy.

Apart from the girdle of pregnancy, cures do occur in which there is a magical extension of the notion that a constriction is physically capable of restraining increase in bulk. Tumours, and especially goitre, are treated in this fashion.

In Derbyshire, Lanarkshire, and elsewhere in Britain, as well as in Switzerland and Germany, a favourite method of restricting the growth of the enlarging thyroid of goitre is to bind a silk thread, preferably red in colour, three times round the neck. In Essex for an "enlarged neck" they used to fasten a snake skin, sewn in a piece of black silk, round the neck for the same reason. The belief is akin to that recorded by Pliny that "if young twigs are made into a collar and put round a cock's neck it will never grow."

Psychologically such cures belong to the same order of magic as the "measuring" cures, and as that which believes that if you pass your leg over a child's head you will stop it growing.

(There is another form of homœopathic magic which may possibly have participated in the evolution of band and ring cures, and that is the well-known magical use of knots. But as I have been unable to find any instance in which the connection is clearly manifested, I do not propose to spend any time in discussing it.)

We turn now to a variety of the constriction cure, which although similar in appearance to those we have just been describing, is quite different from them in its origin and nature. I refer to the constriction of the extremities in the treatment of hæmorrhage, the vogue of which is widespread.

In Scotland bleeding from the nose is, to this day, quite frequently treated among the people by tying a thread or a string tightly round the thumb.

In the province of Bari, in Northern Italy, menorrhagia is treated by binding a rope round the waist, the wrist, and the ankle of the patient, and,

if that fails, then threads of black wool are tied round each of the fingers and toes.

In Bavaria the same disorder is treated by encircling the little fingers of both hands with red silk thread, and as many times as the thread is wound round the finger by so many days is the duration of the discharge reduced.

As far as my reading goes no explanation of this method of treatment has hitherto been offered, and the custom has obviously nothing whatever in common with the modern rational practice of uniformly bandaging the limbs in the treatment of the effects of severe hæmorrhage. At first sight, indeed, the constriction treatment of bleeding would seem to be simply nonsensical or fanciful. But such a conclusion would be merely a confession of ignorance. There is always some sort of reason for every folk-cure.

My suggestion is that the constriction was applied in order to fetter the soul so that it could not escape from the body, and my reasons for this explanation, at first sight so far-fetched, will appear in the course of the following remarks.

PRIMITIVE IDEAS ON THE NATURE OF THE SOUL.

Nowhere, perhaps, in the whole range of folklore are the primitive ideas so fanciful and so pleasing as in that section of early psychology which has to do with the soul, and no ideas have proved to be so capable of expansion and development as these were; an expansion and development which, of course, they underwent during the long course of their evolution under the care of the constructive philosophers.

In their crudest forms probably no very clear distinction exists between the idea of the soul and that of the life of a living being; at all events, we certainly must confess that it is difficult, if not impossible, for us to disentangle the ravelled ideas of early man on this subject. But, in its later developments, we may say that, speaking generally, ancient and uncivilised people seem to mean by the "soul" what we in these days would term the consciousness, or the Ego. While, however, it is true that in many languages the word for a "soul" seems originally to have sprung from the idea of a breath (*spirit*, *ghost*, *animus* related to *ἀνεμος*, etc.), nevertheless the soul was no mere abstraction. It was, on the contrary, an actual physical entity, a material object, which, although perhaps so faint and shadowy as to be invisible to ordinary men, was yet quite plainly manifest to those with clearer vision, of whom, in the olden times, there were many.

Sometimes the soul takes the form of a copy in miniature of its owner—what the ancient Egyptians called the *Ka*. In many mediæval prints, for example, depicting the death of certain people, there may be seen a small figure emerging from the mouth. This little mannikin, who is, so to speak, the *genius loci* of the human body, resembling the tree-spirit or the river-spirit of polytheism, resides within the body; in the head generally, sometimes in the chest. He never seems to be found below the diaphragm, where, to be sure, in women at all events, he would probably have found his claim to supremacy contested by another creature, the uterus namely. Upon his behaviour the health of the owner depends to a large extent. In some parts of the world it is said that, if he falls down, epilepsy will result; if he is enticed away, and a dog's soul takes his place, the host will suffer from hydrophobia, and so on.

But there is another and probably more widely distributed notion than this of the soul as a mannikin, or *Ka*, a notion which is due to the observation that, like the uterus, the soul has a tendency

to wander away from the body, slipping out by the mouth or nose. Fortunately, such absence does not necessarily cause death, unless, that is to say, it stops away too long. No doubt when death takes place the soul does forsake its tenement, and for this reason some savages strive to keep their dying friends alive by stopping up the mouth and nose. But in the ordinary way, when the soul goes a-wandering, all that happens is that the owner falls asleep. Sleep, in other words, is the temporary absence of the soul, and dreams are the adventures it encounters while out of the body. At the same time its absence, albeit only temporary, is not wholly free from danger, as some accident may intervene to prevent its return. If the position of the sleeping body be changed, for example, or if some mischievous person disguise the sleeper, as when a moustache is painted on a slumbering lady's face—a shameful trick, equivalent to murder in the eyes of the people of Bombay—then the home-seeking soul gets bewildered, and, like bees whose hive has been shifted, it is unable to find its way back into the body again, so that the sleeper dies without waking. For this reason, also, it is a dangerous thing to rouse a person suddenly from sleep, before, that is to say, the soul has had time to flit back again.

By a natural extension of this belief illness, and especially illness characterised by a loss of consciousness, such as syncope, epilepsy, coma, and the like, is frequently attributed to the withdrawal of the soul from the body.

These ideas are early man's reply to the still unanswered questions: What is sleep? What is unconsciousness? What is death? And the answer, although it may strike us as naïve, is by no means absurd or irrational. It is only another way of saying that there is a Something which comes mysteriously and as mysteriously departs; when it is present, the man is alive—he can see, hear, speak, move, and behave as a sensible being; when it is gone on a short journey, he is half-dead,—the body is warm and the breath comes and goes, but only in an automatic fashion; when it goes for good, all vital processes cease and the person dies.

By a simple process of what we call imagination or metaphor, but what the uncultured man regards as actual fact, this mysterious flitting entity takes the form of a winged creature—a bird, a bee, a moth, or a butterfly.

We have already seen that the Egyptian *Ka* represents the soul-mannikin of early culture, but the Egyptians also found room in their theology for the winged soul, which they distinguished from the *Ka* and figured in the hieroglyphs as a man-headed hawk—the *Ba*. (The popular notion that the Egyptian *Ka* is the equivalent of the "soul" of modern European thought is an error. The Egyptians, as a matter of fact, divided man into no fewer than nine parts, including the physical body—*Khat*—a minuteness of analysis which has no parallel in any philosophy since theirs. It is true that attempts have been made to show that this nine-fold Egyptian structure is the same as the tripartite division of Græco-Roman and modern European philosophy into body, spirit or life, and soul or consciousness, but they are not convincing.)

In ancient Greece the soul was a pigeon or a butterfly. Pigeons, it was said, first made their appearance in that country at the time of the wreck of the Persian fleet off Mount Athos, and in other parts of the world also there are those who see white birds emerging

from the waves when ships go down. The dove is, indeed, perhaps, the most widely-distributed form of the soul. Its significance and importance in the Christian religion is evident from the facts that it was often carved upon tombstones, and that the Holy Spirit took the form of a dove. And the curious association of the dove with illness, and especially with death, is exemplified in the following excerpts from the folk-lore of the subject.

Grimm notes that over the graves of the Lombards poles were set up with pigeons on them. (Just as the man-headed hawk is figured upon the ancient tombs of Egypt.)

Presumably, also, such beliefs are responsible for the practice of applying pigeons to the feet of the dying, as Pepys informs us was done when the queen of Charles II. was sick unto death.

In Scotland, "pigeons were left fluttering in their dying agony against the dying man's feet." "Early in the morning a near relative would remove the pigeons and carry them to a place where the dead and the living did not cross, that is, to the top of a precipice," and there leave them. (Black.)

In many parts of England there is an old superstition that dying people cannot take leave of life on a bed of pigeons' feathers, and for a patient to ask for pigeons to eat is looked upon as a very bad sign. On the other hand, there is a popular belief in some mysterious nutritive value in pigeons and pigeon-broth for sick people. Again, Fernie records the belief that "it is considered a sign of approaching sickness if a pigeon comes and accidentally perches on a table; and, if on bed or a chimney-piece, of death, especially if the pigeon be a white one."

English medicine in the seventeenth century considered pigeons valuable in palsy and for aged and phlegmatic men—supplying them with life, as it were.

There is a superstition in many parts of England, particularly in the West Country, that dissolution cannot take place unless the window is opened to allow free egress to the soul. A prolongation of the death agony is due, it is supposed, to the vain efforts of the soul to escape, and in order to put an end to the suffering, the window must be opened, when the struggling soul will emerge and the sufferer be at rest. That the death-agony can be shortened by so doing is a fact, as I can testify, the reason probably being, as Sir Lauder Brunton pointed out many years ago, that the lowering of the temperature in the room when the window is opened administers the *coup de grâce* to the patient. It is said, also, that the attention of the watchers is drawn to the window by a dove tapping at it, the dove being the means of carrying the soul into space.

(In the estimation of the meaning of folk-cures and practices regard should be had only to their general trend. When we descend to particulars we lose ourselves in a maze of inconsistencies and contradictions. Thus in the above, the pigeon is seen to be at one time a danger, at other times a safety. But the general tendency is clear enough, and shows that the pigeon was connected with death, or, in other words, with the flight of the soul.)

In this connection the marvellous image, or vision, of Plato, that greatest of mystics, comes to our recollection, where he figures the soul as a bird-like creature, which in its sojourn in the flesh, and from its contact with sin and the world, tends to lose its sustaining plumage and to become a mere denizen of lower space—being "earth-bound," to use the modern theosophical phrase—but which also, by the love of wisdom and the exercise of well-doing, may acquire new wings wherewith it may soar into the lofty and ethereal realms of truth with the sureness and power of the eternal gods themselves. For every sin committed, so to speak, a feather is lost, and with it a modicum of

buoyancy; while, on the other hand, with every good and noble thought or deed, a new feather is obtained and fresh buoyancy acquired. Here, also, we may recall, as fundamentally akin to the Platonic idea, the Egyptian doctrine of the weighing of the dead man's heart against a feather by Thoth in the presence of the gods. And so we see how philosophical and religious beliefs and aspirations of the most sublime character may occasionally spring from what we have been long accustomed to regard as nothing but the vain and empty superstitions of vulgar and ignorant people.

Another beautiful idea is that of the Greeks who saw in the butterfly ($\psiυχίη$) emerging from its chrysalis the soul (also $\psiυχίη$) issuing from the body at death, a belief which, although employed metaphorically or as a type by the Platonic philosophers, was in the popular mind of the time an actual and genuine occurrence.

(We may observe, in passing, that both Germans and Romans differentiated the soul from the mind: $\psiυχίη$ *animus*, the soul, and $νοῦς$ *mens*, the mind; while *anima*, life, is akin to *ἀνεμος*, wind or breath. *Animus* and *anima* are "next door to each other," as Grimm says.)

Among the uncivilised races of the present day the idea of the soul as a winged creature is very common indeed, and Frazer gives a long list of examples.

The bee, also, is met with in some old Scots tales creeping out of a sleeper's mouth and flying away into the dream-world.

The next step we take in our inquiry brings us within sight of our goal, for it has to do with the curious association of the soul with the blood. Obviously the connection is due to the fact that bleeding tends to end in the flight of the soul, or in syncope and death. The soul, as Grimm says, "has her seat in the blood, and as that ebbs away, she escapes with it," and from this natural observation there spring, he suggests, the pretty myths of flowers or trees growing out of the body after death. Drops of blood turn into yellow flowers, as from the blood of Ajax a herb sprouted. Further, one of the old German sagas speaks of the soul flowing away out of the body, while, in the Iliad, the soul escapes through a gaping wound, as if it were an extra mouth, so to speak. Then there is the ancient Hebrew doctrine that "the blood is the life," and Sallust's remark (for which I am indebted to Fernie), "*Sedem animæ in extremis digitis habent.*"

Here we tread very close upon the heels of the old medical belief that the arteries contained the soul, but caution forbids me claiming this as an offshoot from the more ancient idea, in view of the explanation usually given that this belief arose from the observation that after death the arteries are found to be empty.

We have been dealing principally with the departure of the soul, but there also arises the equally interesting question as to the time of the arrival of the soul in the body, a question which during the Middle Ages was, for religious reasons, a warmly debated topic of discussion.

According to most folk-beliefs it would seem to enter the body at birth, but the advent of the soul is also in many places, dated to the time of the quickening of the fetus *in utero*.

The soul, then, being bird-like in nature, and liable to embarrassing and perilous absences, it becomes important to devise a means to prevent its escape. For this purpose what could be better than a snare or a tie of some kind?

On the return of a Burmese or Shan family from a funeral, a tendency has been noticed for souls to

take flight. In order to prevent such a calamitous ending to an already sorrowful occasion, the old men are careful to tie strings round the wrists of each member of the bereaved family.

Bartels figures a soul-snare which the Harvey Islanders employ when they wish to compass the destruction of an enemy. It consists of a series of rings or loops made of rope, which is hung upon a tree in the neighbourhood of the intended victim. When that unfortunate man catches sight of this magical gin, knowing only too well what it means, he returns to his dwelling, lies down, and very soon gives up the ghost in real earnest.

This kind of knowledge gives to us a new understanding of the Psalmist when he says: "Our soul is escaped as a bird out of the snare of the fowler; the snare is broken and we are escaped."

We have already cited instances of ligature cures. Here is another in which, it is interesting to note, the fear of bleeding is not present. "The Minangkabauers, of Sumatra, fasten a skein of thread or a string round the wrist or loins of a woman in childbirth, so that when her soul seeks to depart in her hour of travail it may find the egress barred." (Frazer.) And finally, here is the same cure, in which the fear of hæmorrhage is said to be the reason for the ligature: in Franconia, and also in other districts of Germany, a rather common practice is the binding of the arms and legs at the elbows and knees during labour in order to hinder bleeding. One often hears a trifling *post-partum* hæmorrhage credited with being the cause of diseases which appear later on. (Ploss and Bartels.)

It is interesting to note, in conclusion, that the ligature cure was practised by ancient and mediæval doctors of good standing. Paulus Aegineta, for example, treated *Deliquium animi* (which Adams translates by "the absence or want of the soul"—evidently what we nowadays term "syncope" or "fainting") by ligatures round the arms or legs, and the same method was recommended by him for epistaxis and hæmoptysis, while he gives it the first place in the treatment of menorrhagia.

FINGER-RING CURES.

The popular custom of wearing rings for rheumatism is also very ancient. I am inclined to look upon this particular cure, however, as different in its origin from the soul-strictures we have just been discussing. Probably it sprung from the wearing of charms. For in the early times jewellery in general, and finger-rings in particular, though often doubtless worn simply for adornment, were also frequently made the vehicle of charms, as King has pointed out. Naturally, a band or ligature would be held to be all the more efficacious if the material of which it was composed was made of some magical substance like red silk; if the bandage was decorated with religious symbols; if the ring was composed of some rare or curious metal; or if it bore in a setting a scarab or blood-stone, or some such potent jewel.

An example of this kind of polypharmacy is afforded by the following from the *Complete Housewife* (18th century):—

"To make necklaces for children cutting teeth.—Take roots of henbane, or orpin and vervain, scrape them with a sharp knife, cut them in long beads and string them green; first henbane, then orpin, then vervain, and so do till 'tis the bigness of the child's neck. Then take as much red wine as you think the necklace will suck up and put into it a dram of red coral, as much peony-root finely powdered. Soak your beads in this twenty-eight hours, and rub the powder on the beads."

Many of the herbal remedies, like henbane, orpin, and vervain, owed their reputation to qualities magical and mystical, and not in the first instance, at all events, to any actual pharmacological effect or true therapeutic power. In many cases, as I have shown elsewhere, the real efficacy of the remedy remained undiscovered until patients began the

habit of swallowing the herb in order to bring it more closely into union with the body and personality.

In conclusion, we may for convenience summarise the reasons which led to the use of strings and rings in medicine as follows:—

(1) Circular pressure, applied for the relief of pain.

(2) The same, applied with the object of physically restraining the continuing growth of a swelling or tumour.

(3) The magical extension of the last-named. (Related also to "measuring" cures).

(4) Bands and ligatures put on to prevent the escape of the soul.

(5) Religious or magical bands or rings worn as charms or amulets.

It is possible that the mysterious rite of circumcision may, in the first instance, have originated in an effort to avoid the real or magical effect of an anatomical constriction inhibiting a natural function, but to discuss this topic would lead me far from the subject-matter of the present communication; consequently I prefer to postpone its consideration for the time being.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

CONSCIENTIOUS OBJECTORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—We hear much just now of the views of "conscientious" objectors—men who say they object not merely to combatant service, but to any service which would assist our militant forces.

The ordinary man of common sense refuses to believe in any religious view which condemns a man for resisting injuries. The "pacifists" apparently often hold, not only that non-resistance to personal injury is the part of a true Christian, but that even to help by violence another person who is being oppressed is contrary to the true principles of Christianity. This is a difficult thing to maintain, and most men rightly reject such views without troubling to examine them. It is easy to set them down as the excuses of cowards, but this cannot always be the case. A real coward is very rare, and merits our pity as much as our contempt, but there really do seem some men of average courage who think that it is wrong to fight, even for a just and righteous cause.

They are the victims of false teaching and bad religion. They justify themselves, no doubt, by the "non-resistance" sayings of our Lord. But to tear these sayings out of the context of a life which resisted evil to the uttermost is to render that life meaningless. Our Lord's fierce denunciation of those who misled others, and imposed burdens on others rather than helped to carry them, no less than His violent personal attack on the desecrators of the Temple, is very unlike the attitude of some of our modern religious Pacifists. And how many of those who readily recall the celebrated "Resist not evil" passage also remember Christ's final charge to His disciples, given in view of the whole of their future career: "Now . . . he that hath no sword, let him sell his garment and buy one"?

Any argument may be founded on scraps of texts, but in truth that view of religion which regards it as always first concerned with the preservation of peace is fatally defective; no less so is the opposite view that "The Lord is a man of war." Either view taken alone is corrupting.

Britain before the war was growing ignorant of the very meaning of patriotism, blind to duty, full of half-understood Socialism, and of vague and idle discontent. The fruit of the second view taken alone is—Germany as she was and is. The evils come from taking either view alone. They must be held in union. Both are necessary; both required by true religion. Good pacifism and good militarism are indissoluble allies for a common end, which is the formation of nations, of men, of the human soul.

Religion alternates between the preaching of peace and that of war. Try to expurgate the Bible in the interests of either and see what you get. A Pacifist psalter would misrepresent the spirit of the Hebrew religion; so would a collection of the war-like psalms.

"I will lay me down in peace, for thou Lord only makest me dwell in safety." Yes, but then, "Blessed be the Lord my rock, Who teacheth my hands to war and my fingers to fight."

These sayings explain each other. The moral value of the object for which you fight makes the difference between a religious and an evil fighter. Moments may come when a man must say to his soul, "Now must I fight to the uttermost or I shall have no more peace." More rarely such supreme moments come to a whole race. Such a moment is upon us now. There is no longer any room for doubting that in fighting Germany we are fighting *naked evil*. By her declared policy previous to the war, by her methods in waging it, she has removed all room for any doubt. She is the enemy of every free man, the enemy of all Christian civilisations. And against pure evil man must ever be a fighter. If not he will be destroyed, having betrayed his trust as a human being. If the real nature of war was better understood, and the issues involved in this war more clearly seen, I think there would be fewer "conscientious" objectors.

I am, Sir, yours truly,

J. LAWRENCE GREEN, M.A. CANTAB.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have some difficulty in understanding Mr. Gwillim Davies' position, for on the one hand he says he has no sympathy with the actions of these people, but on the other he quotes a Bishop, a popular dictionary, some poets, and a missionary in their favour. More than this, he tries to help them by the old device of damning the plaintiff's attorney, for he accuses the Law of not doing what it has undertaken to do, and of "naked Prussianism." The difficulty of the Tribunals has been

to find the "honest objector," and if Dr. Davies, in the *role* of a modern Diogenes, has found any, he is more successful than I have been, for a greater farrago of nonsense than that served up by most of the conscientious objectors in the Courts I have never read. But if the Law ever did "safeguard the *honest* objector"—not, mind you, the same thing as the *conscientious* objector—it has seen fit to change its mind by ordering general compulsion, through which it is to be hoped these subtle abstentionists will be brought to their proper sphere of duty. Dr. Davies has not been particularly happy in his choice of authorities, for when he says that "words mean what they pass current for" he is distinctly in error, for in truth words often mean what they do not pass current for, they are a false coinage; and in quoting Mr. Arnold Bennett to the effect that the Germans will ultimately realise their national guilt, he just proves that the knowledge will have to be put into them, not that it was an innate sense; their new conscience will have cost much blood and treasure, all of which might have been avoided if they had had an innate sense of right and wrong.

If Dr. Davies has studied modern psychology— which, however, is not apparent from the class of writings he quotes with approval—he must know that it is not any *ipse dixit* which makes the knowledge of right and wrong rest upon education and experience: it is the laborious and experimental reaching of mental philosophy, which, though still imperfect, is yet progressive, and has already proved that many of the mental processes, such as attention and memory, among others, are to be understood in terms of logarithms and algebra. I believe in the Christian religion, though much of the New Testament I cannot, after diligent reading, understand, but I cannot anywhere find authority for innate knowledge of right and wrong, a doctrine which, as I think, would sap our striving to do what is right, and would leave us merely passive recipients of things as they happen to us, and would leave us an easy prey to those who have made up their minds to plunder and aggression. The very futility of these imaginary "faculty processes," their powerlessness to effect what they are supposed to do, is enough to make one doubt *prima facie* their existence, but the theory is so ready to hand for those who are of strong emotional tendencies and are propagandists of selfish objects, that the real nature of mental processes is neglected, and old terms are raked up which were used in the dark past to conceal ignorance. The action of Parliament last night makes it unnecessary to prolong discussion on this subject. The conscientious objectors will be summarily absorbed, we shall be saved from the public enumeration of their banalities, and it is quite likely that their new experiences will prove to be the creator of a new consciousness so different from the old self that they will be ashamed to own that they ever held it.

I am, Sir, yours truly,
T. CLAYE SHAW.

Weymouth Street, London.
May 5th, 1916.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. L. Gwillim Davies and Dr. Claye Shaw are foemen worthy of each other's steel, and it is to be hoped that they will fight their polemic to a finish, for the edification and instruction of your readers. It would be impertinent for me to intervene in such a combat, except to say merely that I am on the side of Dr. Claye Shaw, and that it is to me unthinkable that any intuition can exist beside the instincts of the animal except such as are

developed by the influence of environment, of course, in the widest sense of that word, especially religion, education, and parental example.

My main object in writing is, however, to present the controversialists with the following string of quotations from a store which they may, if they please, profitably, perhaps, explore for themselves:—

"Conscience does make cowards of us all."—Shakespeare.

"O the cowardice of a guilty conscience."—Sir Philip Sidney.

"A good conscience likes to speak out."—Pausanias.

"The guilty conscience fears when there's no fear."—Rowland Watkyns.

"My conscience hath a thousand several tongues."—Shakespeare.

"Conscience is a god to all mortals."—Menander.

"Conscience is but a word that cowards use."—Shakespeare.

"Conscience is the chamber of justice."—Origen.

"Conscience is the sentinel of virtue."—Johnson.

"Conscience is the voice of the soul."—Rousseau.

"Conscience is wiser than science."—Lavater.

"He is but naked . . . whose conscience with injustice is corrupted."—Shakespeare.

"Les lois de la conscience que nous disons naistre de nature, naissent de la coustume."—Montaigne.

I am, Sir, yours truly.

A STUDENT OF PSYCHOLOGY.

May 5th, 1916.

THE REFORM OF VOLUNTARY AID
DETACHMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The first step towards the reform of evil is its proclamation with a view to its general recognition.

The constitution of Voluntary Aid Detachments must surely be revised, for it has now been tried as by fire and found wanting. Because these bodies have done good work, it does not follow that they need no reform. They are being used as it was never intended that they should be used when they were instituted, and though Sir Alfred Keogh wrote that "their essential function is improvisation," they are none the better for being themselves improvised, and the best of them were established "subject to alteration to suit military requirements." Your leader writer may take it that the time for their alteration has fully come.

I am, Sir, yours truly,

TEKEL.

May 6th, 1916.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN
IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, MARCH 24TH, 1916,

The President, GIBBON FITZGIBBON, M.D.,
F.R.C.P.I., in the Chair.

MYOMATA FROM A CASE OF CÆSAREAN MYOMECTOMY.

DR. GIBBON showed a specimen of above. The patient was first seen nearly four years ago, when she was thirty-two years of age, and had been married for nearly a year. She was in good health, and not in any way inconvenienced by the condition of her uterus. She menstruated regularly. She did

not wish to undergo an operation if she could become pregnant without doing so. The largest tumour, which was then about the size of an apple, was situated apparently in the layers of the left broad ligament and attached to the supra-vaginal portion of the cervix. It was pointed out to her that there might be trouble during labour if she did become pregnant, and removal of the tumours was recommended. The operation was declined. She returned within a year for her confinement. The fibroid in the pelvis did not then seem much larger. It was possible to push it well out of the way, and to feel the presenting part of the foetus, which was the breach. Labour progressed normally, and the tumour was pulled up satisfactorily. When the os was nearly fully dilated it was possible to feel the tumour above the brim, and the breach entering. The mother and child were then in good condition. About half an hour later the foetal heart could not be heard, and examination showed that the cord had prolapsed past the tumour through a fully dilated cervix. The child was extracted at once, but was dead. The patient promised to return for the removal of the tumours, but did not do so. She returned six weeks ago for her second confinement. The pelvic tumour was now the size of a small melon, and so much in the way that it was not possible to feel the presenting part, which was the head. A Cæsarean section was performed before labour started. The child was extracted alive, and the uterine incision closed. There was no difficulty in removing the tumours, two of which, including the largest, were subserous, the remainder being interstitial. There were five tumours in all. There was no more bleeding than if the uterus was not pregnant, and the extent to which the uterus could be drawn up outside the abdominal incision made the myomectomy easier than it generally is. It was intended to allow the patient to deliver herself if she should become pregnant again, and it was submitted that Cæsarean myomectomy is the proper treatment for labour obstructed by fibroids when the uterine cavity is aseptic.

Sir WILLIAM SMYLY said that one of the most interesting questions in connected with Cæsarean section was whether the uterine scar could be trusted in subsequent labours, and in that respect he considered that this case differed from the general rule inasmuch as not only had the woman already borne a child per *vias naturales*, but the cause of the previous obstruction having been entirely removed, no unusual strain upon the uterine wall was to be expected.

Dr. NEILL said that he remembered a patient who had a Cæsarean section performed for myoma obstructing labour, and who at a subsequent labour, about twelve months afterwards, was delivered by forceps without any difficulty.

The PRESIDENT said he thought a myomectomy after Cæsarean section was better than the usual procedure of hysterectomy. He thought that the patient should be allowed to deliver herself in any consequent confinements. He held the view that when the cervix and vagina had already been dilated by the delivery of a child, and there was no obstruction, the scar in the uterus would hold, but where Cæsarean section was done on a *primipara* the risk of subsequent labours would be too great.

SOME POINTS IN CONNECTION WITH PUPERPERAL ECLAMPSIA.

Sir WILLIAM SMYLY read a paper on the above.

Dr. NEILL said that a patient of his who suffered from albuminuria with no convulsions had very severe *post partum* hæmorrhage. On the ninth day she had several severe fits, and was unconscious for four days. For eight days nothing was given but

water and lemonade. Bicarbonate of soda solution, 1 dram to a pint of water, was injected under the breasts. She recovered.

Dr. GIBSON said that Sir William Smyly had particularly raised the question of high blood pressure and venesection. High blood pressure was valuable in that it helped to promote excretion of the poisons, but its evil effect was the strain it put on the poisoned heart. Its value, when taken in conjunction with other symptoms, lay in the fact that when a patient with high blood pressure and treatment intended to eliminate the poisons, and prevent any additional poisoning, did not improve, she must be considered as drifting to coma and death, and should have her uterus emptied. He taught students that this matter could be settled within a few days during the so-called pre-eclamptic toxæmia when proper treatment was adopted and repeated examinations were made of the patient's general condition, blood pressure, pulse rate, urine, eye symptoms, etc. He regretted that Sir William Smyly did not touch on the question of prevention. Patients should be made familiar with the early symptoms of the toxæmia of pregnancy. He had three cases of death without convulsions, and cases of death after one or two convulsions. The *post-mortem* examination showed degeneration of the kidneys and liver of such extent that they could not have survived. On the other hand, patients frequently reacted to the poisoning by developing vomiting or convulsions, etc., at an early stage of the toxæmia, and with appropriate treatment they should recover. Unfortunately, however, the majority of hospital patients, not being warned, took no notice of the minor symptoms which would have indicated the danger. As regarded venesection, he had found it of use in controlling the convulsions. Its good effect depended on its early use and the amount of blood removed. He consequently always bled his patients, from twenty to forty ounces, at once. It had stopped the convulsions in many of his cases, and with other treatment had helped towards their recovery. In some cases, although the fits were controlled, he found there was no other improvement in the patient's condition. He believed that very many of the good results got by early operation were due to the bleeding induced.

The PRESIDENT said he thought the present nomenclature satisfactory. All the conditions might be due to toxæmia, which might be the primary disease, while the hæmorrhage, vomiting and fits were only the individual exhibition of the disease. As to the treatment, he thought that bleeding, when carried out as it was fifty or sixty years ago, gave good results, but he would follow the treatment introduced by Dr. Tweedy as probably the best at present.

In reply, Sir WILLIAM SMYLY said that the main point in his paper was to show that there was a definite disease, and that convulsions, coma, hæmorrhages, albuminuria, and high blood pressure were only complications of that disease. It was desirable that they should be included under one name, and not treated as separate entities.

SPECIAL REPORTS.

MEDICAL WAR HONOURS.

A Supplement to the *London Gazette* gives a list of awards and promotions for services in connection with the war:—

ORDER OF THE BATH.

The King has been graciously pleased to give orders for the following appointments to the Most Honourable Order of the Bath for distinguished

service in the field. The appointments to date from January 1st, 1916:—

To be Additional Members of the Military Division of the Third Class, or Companions, of the said Most Honourable Order: Temporary Colonel William Hunter, M.D., F.R.C.P., Army Medical Service; Temporary Colonel Charles Alfred Ballance, M.V.O., M.B., F.R.C.S., Army Medical Service; Temporary Colonel Arthur William Mayo Robson, C.V.O., F.R.C.S., D.Sc., Army Medical Service; Temporary Colonel Vincent Warren Low, M.D., F.R.C.S., Army Medical Service; Temporary Colonel James Purvis Stewart, M.D., F.R.C.P., Army Medical Service; Temporary Colonel Charters James Symonds, M.D., F.R.C.S., Army Medical Service; Temporary Colonel William Thorburn, M.D., F.R.C.S., Army Medical Service; Temporary Colonel Charles Snodgrass Ryan, M.B., Army Medical Service (Colonel, Australian Army Medical Corps); Temporary Colonel Frederic Dougan Bird, M.B., F.R.C.S., Army Medical Service; Temporary Colonel Sir Victor Alexander Hadon Horsley, F.R.S., M.B., F.R.C.S., Army Medical Service.

ST. MICHAEL AND ST. GEORGE.

The King has been graciously pleased to give directions for the following promotion in and appointments to the Most Distinguished Order of Saint Michael and Saint George, for distinguished service in the field. To be dated January 1st, 1916:—

To be an Additional Member of the Second Class, or Knights Commanders, of the said Most Distinguished Order: Surg.-Gen. William Babbie, V.C., C.B., C.M.G., M.B., K.H.S. To be Additional Members of the Third Class, or Companions, of the said Most Distinguished Order: Temporary Col. Alfred Herbert Tubby, M.B., F.R.C.S., Army Medical Service; Temporary Col. Archibald Edward Garrod, M.D., F.R.S., Army Medical Service; Temporary Col. Fleming Mant Sandwith, M.D., F.R.C.P., Army Medical Service; Temporary Col. William Henry Willcox, M.D., F.R.C.P., Army Medical Service; Major (Temporary Lieut.-Col.) Creighton Hutchinson Lindsay, M.D., R.A.M.C., T.F. Canadian Army Medical Corps: Lieut.-Col. Frederick Etherington; Lieut.-Col. Samuel Hansford McKee; Major Evans Greenwood Davis.

D.S.O.

The following have been appointed Companions of the Distinguished Service Order: Lieut.-Col. Ernest Victor Gosling, R.A.M.C., T.F.; Major John Grenvill Bell, M.B., R.A.M.C.

MILITARY CROSS.

The Military Cross is awarded to: Temporary Captain Walter Netherwood Rishworth, M.B., R.A.M.C.

INDIAN GALLANTRY IN THE DARDANELLES.

It is announced in the *London Gazette* that his Majesty the King-Emperor has conferred the under-mentioned reward for gallantry and distinguished service at the Dardanelles, with effect from January 1st, 1916, inclusive:—Second Class Indian Order of Merit: No. 880 1st Class Sub-Assistant Surgeon Ghaus Muhammad, Indian Medical Service.

MEDICAL SERVICE IN GALLIPOLI.

THE following names, which through various causes could not be included at the time, are now added to the list of officers mentioned in General Sir Ian Hamilton's despatch of December 11th, 1915, published in a supplement to the *London Gazette* dated January 28th, 1916:—

MEDICAL SERVICES.

Army Medical Service and R.A.M.C.—Surg.-Gen. W. Babbie, V.C., C.B., C.M.G., M.B., K.H.S., Temp. Col. C. A. Ballance, M.V.O., M.B.,

F.R.C.S., Temp. Col. F. D. Bird, M.B., F.R.C.S., Temp. Col. A. E. Garrod, M.D., F.R.S., Temp. Col. Sir V. A. H. Horsley, F.R.S., M.B., F.R.C.S., Temp. Col. W. Hunter, M.D., F.R.C.P., Temp. Col. V. W. Low, M.D., F.R.C.S., Temp. Col. A. W. M. Robson, C.V.O., F.R.C.S., D.Sc., Temp. Col. C. S. Ryan, M.B. (Col. Australian A.M.C.), Temp. Col. J. P. Stewart, M.D., F.R.C.P., Temp. Co. C. J. Symonds, M.D., F.R.C.S., Temp. Col. F. M. Sandwith, M.D., F.R.C.P., Temp. Col. W. Thorburn, M.D., F.R.C.S., Temp. Col. A. H. Tubby, M.B., F.R.C.S., Temp. Col. W. H. Willcox, M.D., F.R.C.P., Major J. G. Bell, R.A.M.C., Lieut. W. N. Rishworth, R.A.M.C.

Royal Army Medical Corps (T.F.).—Lieut.-Col. E. V. Gosling, Major (temp. Lieut.-Col.) C. H. Lindsay, M.D.

Canadian Army Medical Corps.—Lieut.-Col. F. Etherington, Lieut.-Col. S. H. McKee, Major E. G. Davis.

OBITUARY.

DR. F. H. VILLANUEVA, L.R.C.P. AND S., L.S.A., PECKHAM.

WE regret to learn of the death of Dr. Francis Horton Villanueva, of Peckham-road, who died on April 29th, after having been in failing health for some time. Educated at Charing Cross and Birmingham, he qualified L.M. Dublin in 1876, and L.S.A. in 1880. The deceased gentleman, who was for many years medical officer to the Camberwell Dispensary, was the son of Fernando Pedro Joaquin Lorenzo Francis Javier Villanueva, Spanish Consul for Birmingham for 40 years, and nephew of Joaquin Lorenzo Villanueva, Ambassador to the Court of Rome. His father was the son of Lorenzo Jadeo, Marquis of Villa Franca.

MEDICAL NEWS IN BRIEF.

Treatment of Venereal Diseases.

In the House of Commons on May 4th, Mr. Asquith, replying to Mr. King, stated that the Government have decided to adopt the recommendations of the Royal Commission as to the diagnosis and treatment of venereal diseases, and arrangements were being made accordingly. It had been decided that 75 per cent. of the cost of these arrangements, which it was hoped might be undertaken with the co-operation of the local authorities, should be defrayed by means of a grant from the Exchequer. He could not at the moment promise legislation on the other recommendations of the Commissioners, some of which raised very controversial questions, but the whole matter was receiving the earnest attention of the President of the Local Government Board.

Sheffield Panel Doctors' Loss.

THE Clerk (Mr. W. E. Hart) has made an interesting report to the Finance and General Purposes Sub-Committee of the Sheffield Insurance Committee, with regard to the amount available from the Insurance Commissioners for medical benefit.

He points out that the sum of £6,628 7s. 5d., which the Commissioners had credited for settlement in respect of medical benefit for the period ended December 31st, 1914, was considerably less than that which the Committee might have expected to have received in view of the average counts of the register for that period, as compared with the year 1913. Though there were 12,022 more insured persons on the register in 1914 than in 1913, instead of receiving £3,497 10s. 5d. more than was received in 1913, the Committee are actually receiving £3,650 14s. 9d. less.

In the year 1913 the credit was based on a capitation rate of 8s. 5.16d., such being the proportion of 8s. 6d.

for the medical year, which was three days less than a full year, and at this rate the number of insured persons was 152,500, which implied that the register was inflated by 4,420 insured persons, or about 3 per cent. As the medical year 1914 was eleven days short of a full year, the amount of the capitation fee is 8s. 2.936d., so that the Committee are being credited with 147,082 insured persons, an inflation of 21,860, or a percentage of 12.94.

The amount available for payment to practitioners—namely, £48,863 2s. 7d. (which includes £3,494 19s. 9d. transferred from Sanatorium Benefit Fund in respect of domiciliary treatment), is only sufficient to pay practitioners 95.12 per cent., or 19s. 0.287d. to the £ for the number of insured persons on their lists. This means that the doctors will be discounted on their actual lists, and will receive no payment in respect of over 17,000 insured persons who have made no choice of doctor.

At the next meeting of the Insurance Committee, the Finance and General Purposes Sub-Committee will make a request to the effect that the Insurance Commissioners be asked to receive a deputation from the Committee, together with representatives of the Panel and Pharmaceutical Committees, for the purpose of laying before the Commission the views of the Committee regarding the serious diminution of the amount available to the Committee for medical benefit for the year 1914.

German Typhus Camps.

SIR E. GREY informed the House of Commons on May 2nd that in April and May, 1915, typhus was present in thirteen German prisoner camps in addition to that of Wittenberg, and that, according to unofficial reports, two of these—Altengrabow and Schneidemühl—were abandoned by the Germans. In the case of another prisoner camp—Gardelegen—all the Germans deserted the prisoners except one doctor, who died at his post, and another who acted in a most praiseworthy manner.

Banstead Asylum.

THE London County Council have postponed until the end of the war further action on the scheme for remodelling the large blocks for patients at Banstead Asylum. The scheme provides for alterations which will permit of better classification and treatment of patients. The estimated cost of the work is £47,205.

Widow's Self-Sacrifice.

MR. P. J. DE PARAVICINI, presiding on May 2nd, at the annual general meeting of the Governors of King Edward VII. Hospital, Windsor, said that a bequest of £1,000 had been made to the hospital by a Mrs. Golden in accordance with a wish expressed by her late husband, a clerk for many years in a Windsor bank.

The amount represented Mr. Golden's accumulated savings, which had not been touched upon by his widow, though her means were very limited. Mrs. Golden had even deprived herself of some of the necessities of life in order to preserve the £1,000 intact. He thought that was a glorious instance of self-sacrifice.

The Late Sir William Turner.

At a meeting of the Royal Society of Edinburgh, on April 28th, the first communication was an obituary notice of Sir William Turner, late Principal of Edinburgh University, by Sir James A. Russell. Sir William Turner, he said, was a man of the highest talent, eminently sane and workable, and absolutely free from the want of balance associated with genius. Next to the University of Edinburgh, the Royal Society of Edinburgh held a place near his heart, and of his more important contributions to science 39 were to be found in its Proceedings and 24 in the Transactions.

Cigarettes and "Soldier's Heart."

MR. TENNANT, replying to a question by Mr. J. M. Henderson, says:—"A certain number of cases of disordered action of the heart are occurring—the so-called 'soldier's heart.' This is being investigated in a hospital specially set aside for the purpose. We have no

evidence that the number of cases is increasing at present. By some observers this condition is attributed to excessive cigarette and tobacco smoking, and this is being looked into by skilled experts."

Italian Doctors Called Up.

ITALIAN doctors and surgeons between the ages of 41 and 46, and those belonging to the classes of 1876 to 1896 who have been previously exempted for physical infirmities, are called under arms, with the exception, however, of those employed in public sanitary work. They will receive a daily indemnity and officers' rank.

Herbalist's Claim.

At the Leigh Military Tribunal on May 3rd, a herbalist, aged 26, claimed absolute exemption on the ground that he was in business as a herbalist practitioner. He said he was the only certified herbalist within eight miles, and that he had 40 or 50 visits a week and 200 patients.

Alderman Hunter: Could you not get a medical man to take your place?

The Applicant: Medical men know as much about herbs as a cat knows about the moon.

The Mayor said they would adjourn their decision until June 6, but they advised him to make all the arrangements he could with a view of going into the Army later.

A Doctor's Conscientious Objections.

At the statutory May meeting of Argyll County Council, held in the Court House, Inveraray on May 4th, a report submitted by Mr. J. W. Melles, of Gruinart, dealt with the case of Dr. J. C. MacCallum, Assistant Medical Officer of Health for the county, who was appointed Assistant District Medical Officer on November 17th, 1914. Dr. MacCallum, it was stated, made application to the Lorne District Tribunal for exemption on conscientious grounds. A letter of the clerk to Dr. MacCallum, dated April 22nd, requesting his attendance before the Council, and a reply from Dr. MacCallum, dated April 27th, declining to be present, were read. The Committee having very carefully considered the matter, it was resolved, on the motion of the Chairman, seconded by Mr. Forbes, Islay, to recommend the County Council to give written intimation to Dr. MacCallum of their intention to dispense with his services as assistant medical officer of health from and after three months from the date of notice. The report of the Committee was adopted. Sir James Patten Macdougall ruled that the recommendation of the Committee must come up at the October meeting.

German Buying of Cod-Liver Oil.

A BRIEF reference has already been made in these columns to the rapid advance in the price of cod liver oil. Its value is now at least eleven times the normal figure, and is advancing almost every week. Before the war it could be bought at from 60s. to 70s. a barrel of 36 gallons, and now costs between 750s. and 800s. These are wholesale prices, and the retailer who buys a few gallons would have to pay a price which works out at something like 1s. 6d. for a half-pint bottle.

The amount of oil produced in Norway so far this season is well above the average, but Germany is buying all the oil she can secure and is paying partly in cash and partly in war loan. As the cash payment is about 50 per cent. of the amount of the sale, the producers will clear a good profit even if they lose the rest.

Southport Milk.

IN his annual report on the health and sanitary condition of Southport, Dr. George C. Barnes, the acting medical officer of health in the absence with the colours of Dr. J. J. Weaver, the medical officer, states that the abnormally large number of milk samples reported "short of fat" was due, among other causes, to the weak action of the petty sessions magistrates when adjudicating on cases under the Food and Drugs Acts, and to the greatly restricted use of ground feeding stuffs or dairy meals consequent on increased prices.

Care of Dublin Wounded.

The following *communiqué* was issued by General Sir John Maxwell on May 7th:—

"I desire to express my sincere appreciation of the services rendered during the recent disturbances in Dublin by the medical, surgical, and nursing staffs of many of the city hospitals, and in particular of the gallantry shown by those nurses who exposed themselves to a heavy fire in attending to and removing the wounded.

"Also to the members of the Red Cross and St. John Ambulance Societies and the many medical men and private individuals who gave assistance in attending to the wounded or placed their houses at the disposal of the military for use as dressing stations. In numerous instances these services were rendered at considerable personal risk and under circumstances reflecting the greatest credit on those engaged in them."

Central Medical War Committee.

The following letter from Dr. H. Nicol appears in the *Morning Post* of May 8th:—

SIR.—As the details of the Military Service Bill are now being considered by Parliament, I would suggest that the position of the Central Medical War Committee should be defined in that measure. At present, doctors who enrol do so through the Committee, which selects out of the whole number men as required by the R.A.M.C. It is of the first importance that under compulsory service, the same arrangement should continue, and that the selection of *unenrolled* doctors be entrusted to the Central Medical War Committee, both in justice to the medical profession and to the civilian population.

I am, etc.,

South Kensington, HAMISH NICOL.
May 6th

Patients of Recruited Panel Doctors.

At the meeting of the Insurance Committee for the County of London at Spring Gardens on April 27th, the following recommendation was received from the General Purposes Sub-Committee: "That the order of reference to the Special (War Emergency) Sub-Committee be amended as follows, and as thus amended be approved until further order: To consider and report as to the position of medical practitioners on the panel who have joined or who may wish to join his Majesty's Forces, and the arrangements made by such practitioners for the provision of medical treatment for the insured persons on their panel lists during their absence, and particularly as to the deputies appointed by them; to consider as to the requirements of the dispensing service for the area, and after consultation with the Pharmaceutical Committee to submit to the military representatives a list of persons whose services in the dispensing of medicines are indispensable to the needs of the general population; and that the reference to the Medical Benefit Sub-Committee, so far as it relates to these matters, be suspended."

Cod Liver Oil and Malt for Children.

At a meeting of the Swansea Medical Inspection Sub-committee of the Education Authority, on May 3rd, a letter was read from the Board of Education declining to sanction the supply of cod-liver oil and malt as part of the treatment for anæmic children. It was decided, if the parent could not afford the medicine, to supply it under the provision of meals administration.

Women Druggists.

SINCE the beginning of the war there has been a large increase in the number of women students of pharmacy, and at present there are as many women students as men at some of the principal schools of pharmacy. Before the war there were at the most only a few hundred women on the chemists' register and very few of these were actually employed in chemists' shops. Now such is the demand for women assistants to take the place of young men that any woman pharmacist who advertised for an appointment would receive many offers at salaries ranging from £100 to £200 a year.

Notification of Diseases Order.

In the House of Commons on April 11th, Sir P. Magnus moved an amendment to Clause 5, providing that the fee to be paid to a medical practitioner for every case of notification of disease by him should be, except in the case of measles, 2s. 6d., instead of 1s. as provided in the Bill.

Mr. Hayes Fisher opposed. This economy was suggested by the Retrenchment Committee.

The amendment was negatived without a division.

Royal College of Physicians of London—The Fellowship.

THE following members of the Royal College of Physicians have been elected Fellows:—J. A. Arkwright, E. A. Cockayne, M. G. Foster, C. E. Lakin, H. L. McKisack, J. M. H. MacLeod, C. H. Miller, and H. W. Wiltshire.

The undermentioned, having passed the required examinations, have been admitted to membership of the College:—A. G. Anderson, R. Hill, W. MacAdam, and H. H. Scott.

Dental Scholarships.

THE following entrance scholarships of £20 each in Dental Mechanics have been awarded at Guy's Hospital:—Open scholarship, A. F. Bartle; pupils' scholarship, R. S. Roche.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad. Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Anstralia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

SUPPLEMENT OF THE IRISH MEDICAL ASSOCIATION. In consequence of the disturbed condition of Dublin, and the difficulties which beset printing establishments, we are unable to issue the usual fortnightly supplement, which is posted to all members of the Association. As matters are gradually assuming normal conditions, we anticipate being able to issue the supplement next week.

CITY STREET ACCIDENTS.

DURING the first quarter of this year 243 accidents caused by vehicles occurred in the City of London, of which two were fatal and 241 resulted in personal injury. Of these 126 were caused by horse-drawn vehicles, 11 by tramway-cars, 47 by motor-cars, 37 by motor-omnibuses, six by motor-cycles, and 16 by ordinary cycles.

EXCHANGING CHILDREN.

MANCHESTER Guardians are in communication with some of the London Poor Law authorities with the idea of exchanging children in cases where it is advisable to have them removed from the undesirable influence of their parents.

DR. W. M. C. (Montreal).—A letter addressed to Sir Alfred Keogh, K.C.B., Director-General of the Army Medical Service, War Office, London, S.W., would probably elicit the necessary information.

MATRIMONIAL MISTAKES.

SIR JOHN BRUNNER, at the annual meeting of the Divorce Law Reform Union, said nobody would doubt that there had been more unfortunate matrimonial mistakes during the war than there were before.

WOMEN AMBULANCE DRIVERS.

It will be necessary soon to staff the Western Ambulance Station of the Metropolitan Asylums Board with women drivers owing to the further depletion of the motor driving staff by the calling up of men to join the forces.

THE INCORRIGIBLE.

OLD LADY: "And how did you get wounded, my poor fellow?"
THE HERO: "By not minding my own business, and interfering in this blooming war!"—*The Bystander*.

WOMEN DISPENSERS.

In the military hospitals women dispensers have been so successful that even men over military age are being ousted by the other sex. In fact, the women dispense without men and the hospitals dispense with men.—*Globe*.

CAPTAIN S.P.—The newest book, and the one we can recommend, is "Practical Manual of Bandaging," by Duncan C. L. Fitzwilliams, published by Bailliere, Tindall and Cox. It has been especially compiled for the purposes of the war.

SERUM AMPOULES

GLASS ampoules (to contain anti-tetanus and anti-typhoid serum for the troops), supplied by one of the largest surgical and medical glass instrument makers in the country, have been made by Girl Guides. Before the war all ampoules were imported from Germany.

£8,000 FOR NOTTINGHAM HOSPITAL.

MR. JOHN MERRIMAN, of Sherwood Street, Nottingham, left estate valued at £8,120, of which £5,142 is net personalty. He bequeathed £100 to the Amalgamated Society of Engineers, held at the house of Daniel Dominic. The residue of his estate, estimated at about £8,000, to the Nottingham General Hospital.

WOMEN SANITARY INSPECTORS.

THE Local Government Board have sanctioned the appointment of two women as sanitary inspectors at Greenwich.

M.D.BRUX.—Colloidal silver, known as "Electrargol," is being used for a variety of infective diseases, it is stated with success. In acute septic conditions, intravenous injections of the preparation have been recorded to yield good results.

WITTENBERG MEMORIAL.

A MOVEMENT has been started in Surrey to raise a memorial to the three brave doctors who died at Wittenberg camp from typhus whilst attending to suffering English prisoners.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 10TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY, SUB-SECTION OF PROCTOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Papers—Lieutenant-Colonel Cuthbert Wallace: Rectal Wounds in the Present War. Mr. P. Lockhart Mummery: Injuries of the Rectum resulting from the War. Cases—Mr. P. Lockhart Mummery: Shell Wound of Rectum. Mr. Aslett Baldwin (communicated by): Gumma of Rectum mistaken for Malignant Disease. Lieutenant-Colonel Gordon Watson: Three Cases of Injury to the Rectum from Bullet Wounds.

MONDAY, MAY 15TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Annual General Meeting will be held to receive the reports of (1) Council, (2) Hon. Librarian, (3) Chairman, House and Finance Committee, and to elect Officers and Council for next Session.

TUESDAY, MAY 16TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THERAPEUTICS AND PHARMACOLOGY) (1 Wimpole Street, W.).—4.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Discussion on "The Treatment of Diabetes by Alimentary Rest" will be opened by Dr. O. Leyton. Dr. Spriggs, Mr. Joseph Barcroft, F.R.S., Dr. Ryffel, and Dr. Langdon Brown will take part.

ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY) (1 Wimpole Street, W.).—6 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917.

Vacancies.

Lewisham Borough.—Tuberculosis Dispensary Medical Officer. Salary £250 per annum. Applications to Edward Wright, Town Clerk, Town Hall, Catford, S.E.

Royal Victoria Hospital, Folkestone.—Resident Medical Officer. Salary £200 per annum, with board and laundry. Applications to Secretary.

St. Giles, Camberwell.—Assistant Medical Officer for the Infirmary and Children's Homes. Salary £220 per annum, with apartments, board and washing at the Infirmary. Applications to Medical Superintendent, Camberwell Infirmary, Brunswick Square.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Lady House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38, Barton Arcade, Manchester.

Bootle Borough Hospital.—Junior House Surgeon. Salary £170 per annum, with board, lodgings, and laundry. Applications to the Secretary, 71, Oriol Road, Bootle, Lancs.

Victoria Hospital, Burnley.—Female House Surgeon. Salary £160 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon Secretary, 7 Grimshaw Street, Burnley.

Bolton Infirmary and Dispensary.—Second House Surgeon. Salary £200 per annum, with apartments, board and attendance. Applications to Albert E. Briscoe, Secretary.

County Borough of Dewsbury.—Lady Medical Practitioner. Salary £300 per annum. Applications to H. Ellis, Town Clerk, Town Hall, Dewsbury.

Births.

BARENDR.—On May 3rd, at 65 Rodney Street, Liverpool, W., the wife of Frank Hugh Brendt, M.D.Lond., F.R.C.S.Eng., of a daughter.

CRAGG.—On May 1st, at Wymering, Hampshire, to Cecil Claude Cragg, M.D., Lieut. R.A.M.C., and Florence Everilda, his wife, of Lethbridge, Canada, a son.

DOTTRIDGE.—On May 4th, at 12 Portland Court, W., the wife of Cecil A. Dottridge, M.B., of a daughter.

HEDLEY.—On May 2nd, at 40, Pont Street, the wife of E. W. Hedley, M.D., Capt., R.A.M.C.T., of a daughter.

HEWLETT.—On April 29th, at Redstede, East Grinstead, to Professor and Mrs. R. Tanner Hewlett, a son.

JONES.—On May 4th, at Walmer House, Aldridge, to Margaret, the wife of Captain R. Francis Jones, R.A.M.C. (on active service)—a daughter.

JOY.—On May 3rd, at Manor House, Tamworth, Staffs, the wife of C. H. Joy, M.D., of a son.

MILNE.—On May 4th, at 24 Elsworth Road, Regent's Park, the wife of Robert W. Milne, of a son.

NICHOLSON.—On May 2nd, to Dr. and Mrs. W. A. Nicholson—a son.

STEPHENS.—On May 5th, at St. Giles, Malvern Link, Worcestershire, the wife of H. N. Stephens late Staff Surgeon, Royal Navy—a son.

STEVENSON.—On April 28th, at "Kiama," Weybridge, the wife of Lieutenant W. E. Stevenson, R.A.M.C., a son.

Marriages.

FEHRSEN—NICHOLSON.—On May 1st, at S. Augustine's, Kilburn, Guy Fehrsen, Lieutenant, R.A.M.C., son of the late A. J. Fehrsen, M.D., and Mrs. Fehrsen, of Kroonstadt, S. Africa, to Dorothy Edith Warren, elder daughter of the Rev. J. B. Nicholson, C.F., and Mrs. Nicholson, of Swindon.

GREAVES—TENNANT.—On April 26th, at St. Luke's, Torquay, Edward Harrison Greaves, M.R.C.S., L.R.C.P.Lond., of Penrith, Cumberland (late of Amersham, Bucks), to Emma Hope Tennant, of Green Bank, Rawdon, Yorks.

JACOB—ROECHLING.—On April 28th, at Radlett, Lancelot George, Lieutenant, R.A.M.C., elder son of George Jacob, I.C.S., and Mrs. Jacob, of Clifton, Radlett, to Margaret Sophia, youngest daughter of H. Alfred Roechling, M.I.C.E., and Mrs. Roechling, of High Fields, Radlett.

MCLAY—BARTELT.—On May 6th, at Holy Trinity Church, Folkestone, Samuel McMurrich McLay, Captain, R.A.M.C., second son of Dr. and Mrs. Archibald McLay, of Woodstock, Ont., Canada, to Florrie, only daughter of Mr. and Mrs. W. J. Bartlett, of Woodstock, Ont., Canada.

PEGG—GILBERTSON.—On April 29th, at St. Saviour's Church, Hitchin, John Henry Pegg, B.A., M.R.C.S., L.R.C.P.Lond., of Reigate, to Kathleen Elsie, younger daughter of Dr. and Mrs. J. H. Gilbertson, of Hitchin.

ROBERTS—BROOKS.—On May 2nd, at Presbyterian Church, Kingston-on-Thames, Captain Alan T. Roberts, R.A.M.C., son of Mr. William Roberts, of Sydney, N.S.W., to Marjorie, daughter of Mr. and Mrs. William Brooks, of Sydney, N.S.W.

SMITH—BINNIAN.—On May 2nd, at St. Mark's Church, Hamilton Terrace, T. F. Hugh Smith, F.R.C.S., of Farningham, to Alice Charlotte (Peggy), second daughter of T. W. Binnian, of Kidderminster.

THATCHER—ANNANDALE.—On April 27th, at the Episcopal Church of St. Leonard's, Lasswade, Midlothian, Lewis Hay F. Thatcher, M.D., F.R.C.P.E., Captain, Royal Army Medical Corps, eldest son of Charles H. Thatcher, F.R.C.S. Edin., to Sybil Muriel, third daughter of James H. Annandale, The Vale, Polton, Mid Lothian.

THWAITES—HUME-SPRY.—On April 26th, at Danbury, Essex, Captain Cyril E. Thwaites, R.A.M.C., of 6, Belvedere Road, Durdham Downs, Clifton, to Olive L. H. Hume-Spry.

Deaths.

CHESTER.—On May 5th, at Coney Gree, Up Hatherley, Cheltenham, Colonel William Litchfield Chester (late R.A.M.C.), son of the late Revd. Richard Chester, Rector of Middleton, Co. Cork, Ireland, aged 65.

DONALD.—On May 3rd, at 25 Oakley Street, Chelsea, Robert Donald, L.R.C.P. Edin., Captain, R.A.M.C., T.F., aged 55.

LOWNDS.—On April 28th, James Richard Lownds, M.R.C.S. and L.S.A. London, of the Elms, Newcastle-on-Tyne, and Prestwick Lodge, Northumberland, aged 82.

GODDARD.—On May 2nd, at 46 Montalt Road, Woodford, Essex, Bertram Goddard, M.R.C.S., L.R.C.P., second son of the late Eugene Goddard, M.D., in his 49th year.

HERSCHEL.—On April 25th, at Villa Carlotta, Bordighera, Italy, Lajos Kossuth Herschel, M.D., in his 69th year.

KROHN.—On May 5th, at Arosa, Switzerland, Ronald E. S. Krohn, M.D. London.

LEA.—On May 7th, at 7 Dunkirk Road, Birkdale, Southport, Arnold William Warrington Lea, M.D., F.R.C.S., late of 246 Oxford Road, Manchester, in his 49th year.

MANSFIELD.—On May 7th, at Royal Naval Hospital, Haslar, Gosport, Deputy-Surgeon-General C. J. Mansfield, R.N., M.V.O., in his 55th year.

ROBINSON.—On May 7th, at East Kirkby Manor, Spilsby, Lines, Tom Robinson, M.D., late of Princes Street, Cavendish Square, aged 68.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

My letter box has been unusually interesting of late. It has brought me communications from various districts dealing with such diverse subjects as the claim of Sydney Smith to be considered a wit, the teaching of venereal diseases, non-medical dietician experts, and, that recurring decimal of dismal depression, the British Medical Association. On the first of these questions a correspondent, obviously from the North, writes as follows: "How can you say that Sydney Smith was one of the wittiest men which this country has produced, when it was he who said that it took a surgical operation to get a joke into a Scotsman's head? A remark like that stamps him as a stupid man." Whilst I cannot agree that one unfortunate remark is sufficient to brand a man as stupid, I am prepared to admit that if, having lived in Scotland, Sydney Smith had really said the thing which is so generally attributed to him, it would be sufficient seriously to detract from his reputation for delicate drollery. But he is innocent; he did not say this admittedly coarse and stupid thing.

THE true story is told by his daughter, Lady Holland, in her **The True Story.** biography, which is thus quoted by Walter Jerrold: "William Chambers, in conversation with Sydney Smith, very justly claimed for the Scotch that they had, after all, a considerable fund of humour. 'Oh, by all means,' agreed the witty clergyman, 'you are an immensely funny people, but you need a little operating upon to let the fun out. I know of no instrument so effectual for the purpose as a corkscrew.'" Sydney Smith described real wit "in midwife's phrase, as a quick conception and easy delivery." With all due respect to those concerned, I do not think that this is exactly the type of wit which lives in the North and requires the corkscrew for its liberation.

I PASS from the sublime to the **Unsatisfactory** ridiculous; from Sydney Smith to the **Medical** British Medical Association. A **Recruiting.** correspondent informs me, on what data I know not, that the recruiting of the profession for war purposes, inaugurated at, and managed from, 429, Strand, has not been successful. This is not surprising. It was obvious to

anyone with any knowledge of the feeling in the profession that if the Central Medical War Committee did not definitely dissociate itself from the British Medical Association it would lose a great deal of the prestige and authority which were essential to its success. There has certainly been no lack of warning upon this point in these columns. I have from the outset been very anxious that the work of the Central Medical War Committee should succeed, but it required no Daniel to realise that it was very unlikely to do so if the British Medical Association, with its capacity for mismanagement, and its record of recreant renunciation was allowed to dominate the situation. My correspondent informs me that forasmuch as I ventured to point out the grave disadvantages to the cause of recruiting inherent in this sinister connection between the Central Medical War Committee and the British Medical Association, the latter body sought to compass my freedom by having me cast into prison. But liberty of speech is not yet dead in this country, and to criticise the British Medical Association has not yet attained to the level of *lèse-majesté*. I am still at large.

THE coming of general compulsion **Compulsion and** will, of course, affect the medical **the Doctor.** profession, but it will affect it curiously. As I have already pointed out, the Act enforces service, but it does not enforce medical service. A doctor who has not enrolled can be taken for combatant or pseudo-combatant service, but he cannot be taken for service in his professional capacity. The best thing for medical men of military age to do is to enrol with the Central Medical War Committee; there will then be some chance that their special circumstances will receive adequate consideration, and, if called up, their special knowledge will be utilised for the good of the country. If, however, they allow themselves to be conscripted with Jones, the hairdresser, and Brown, the tallow-chandler, they will have to take their chances as conscripts, and become ordinary tommies, footsloggers, stretcher-bearers, or what not. It is, however, doubtful whether, in the changed circumstances, the Central Medical War Committee will continue its present work. I hear that a change is impending.

I UNDERSTAND that if by a certain date a sufficient percentage of medical men have failed to enrol on the voluntary principle, compulsion will be applied; and that the Central Medical War Committee will cease its enrolling activities and seek to obtain recognition as the Central Tribunal in Medical Affairs. It is sincerely to be hoped that the *démarches* in this direction will not be allowed to succeed. Sir Alfred Keogh must surely by now have realised the unwisdom of having recognised the claim of the British Medical Association to represent the profession. If the Director-General is not cognisant of the fact that suspicion and distrust dog the footsteps of this ill-fated body, even when it is engaged upon a laudable undertaking, it is not for want of having the fact urged upon him; and I imagine that he will think seriously before he again gives official backing to any "committee" which is composed mainly, if not entirely, of nominees of the Association. It is very desirable that there should be a Central Medical Tribunal to deal with medical cases (the lay element ought not to be tolerated), but it is even more important that the tribunal should be so constituted as to command the respect and secure the confidence of those upon whose cases it will have to adjudicate. The recently-appointed Committee of the two Colleges would not, by any means, be an ideal tribunal, but it would be better than the Central Medical War Committee, as at present constituted. Better still would be an entirely new body.

An Unenviable Task. IN any case, the lot of the Tribunal is not likely to be a happy one. If angels were to be sent from heaven to deal with the difficult cases which will surely arise, their findings would give rise to disappointment and their decisions to discontent. It is therefore certain that the work of merely mundane brains and sympathies, however well it may be done, will be subjected to an enormous amount of adverse criticism. And it is reasonable to suppose that, in a large number of cases, the bitterness thus engendered will be directed against the British Medical Association, which, in the gambler's spirit, has staked its all—what remains to it of credit and respect—upon a successful issue to this doubtful enterprise. Those who do not approve of the British Medical Association—and they are many—will contemplate with grim satisfaction its latest and most elephantine effort to play the part of Providence to the profession. In such an adventure an assembly of supermen could scarcely expect to succeed; in the case of the British Medical Association the issue may safely be left to the imagination of those who are acquainted with its methods. It digs its own grave with diligence and ingenuity.

The Treatment of Gonorrhœa. I AM sorry to have disappointed our friend Dr. Hamilton, whose letter appears in another column. And while agreeing with him in principle, I fear I must insist upon a divergence in detail. I did not intend to imply that the older views on the treatment of gonorrhœa

were wrong; I have merely ventured to suggest that latter-day opinion attaches to the sequelæ of the disease an importance which was not emphasised when he, I, and others, assimilated "with avidity" the teaching of x years ago. Then, a gonorrhœal urethritis was regarded very much as a catarrh from any other mucous surface is still regarded, that is, an almost harmless nuisance, the ambulant treatment of which might be trusted to the patient. Now, a gonorrhœal urethritis is recognised as a condition which is fraught with very serious consequences, and latter-day views impose upon the practitioner the duty of warning the patient of the risks he has to face. Most surgeons who deal in these diseases do not, in the early stages, at any rate, entrust the treatment to the victim. They undertake it themselves in order that they may be sure that the disinfection is properly done. The danger of gonorrhœa, like the danger of syphilis, is partly the want of recognition in the early stages and largely the lack of vigorous and prolonged treatment when the diagnosis is certain. If this was taught in the old days I do not think the gospel reached the rank and file.

New Knowledge. DR. HAMILTON enquires "How did they (the present teachers) get their knowledge?" The answer to such a question opens up a very wide field for discussion, into which I am not at present prepared to enter. This, however, I think I may say without offence, that men whose whole time is given over to the study of one branch of a subject may reasonably be expected to know more about the latest developments in the theory and practice of that branch than those whose energies are necessarily spread with some approach to impartiality over many fields of enquiry. I do not know, but I imagine that if Dr. Hamilton were to pay a visit to the Lock Hospital to-day, he would find that treatment there is very much altered from what it was in the days of Berkeley Hill and those who immediately succeeded him.

Mr. Eustace Miles. I HAVE received a courteously contentious letter from Mr. Eustace Miles, which is unfortunately too long for publication in *extenso*, in which he deals with a good many questions relating to ethics and dietetics. The most important debateable point which he makes is summed up in the following paragraph. "Well, then, just as he (the doctor) must recognise the expert in massage and physical culture (except for a few doctors, who have studied this important means to health); just as he must refer patients to them because he has not made himself master of these studies and practices; so why should he not try to learn all he can from dietetic experiments, instead of closing the door to their researches, by abuse?" This is, of course, a very specious argument which my readers will scarcely fail to recognise as a clever evasion of the real question at issue. Massage and "physical culture" are a means of treatment which may safely be entrusted to those who have special facilities for carrying them out, in cases which are deemed suitable by medical men. They are on the same plane with

drugs, the mere dispensing of which is handed over to a specially qualified chemist. The moment the masseur, the physical culturist, or the chemist takes upon himself to apply his remedies without the intervention of a medical man, he is arrogating to himself the competence to make a diagnosis and prescribe a suitable treatment, a pretension which even the ordinary common sense of the ordinary man, to say nothing of the medical man, cannot possibly concede to him.

IF Mr. Eustace Miles were to place himself on the same plane with these others and be content to carry out the dietetic prescriptions of qualified medical men, I for one would not quarrel with him. But he does a great deal more. He makes a diagnosis and prescribes a treatment, and in so doing he invades the territory of regularly qualified practitioners, which, as he is not himself regularly qualified, is a position which we cannot possibly recognise. Mr. Eustace Miles may very likely know, as he claims to do, a great deal more about foodstuffs than we do. But then, an intelligent dispensing chemist could teach most of us a great deal about the behaviour of drugs and the properties of particular preparations. In neither case does this special knowledge entitle the holder to speak with us on equal terms of problems in physiology, pathology and therapeutics.

The Fallacy.

I OFFER my humble congratulations to Dr. Pritchett, the Medical Officer of Health for Rochester, as being, so far as I know, the first health officer to raise his official voice against a dangerous, disgusting and selfish nuisance to which I have frequently called attention in these columns. In his recently-published Annual Report to the Town Council, Dr. Pritchett writes as follows:—"The City of Rochester is infested with an extraordinary number of dogs, which are to be seen wandering about the streets, singly or in groups, at all hours of the day, and without being under the slightest control. A dog unless he is employed to some useful purpose, is a luxury, and the people who want to enjoy such luxuries should pay for them, particularly as their enjoyment inflicts annoyance, not to say danger, on other people. No person should be allowed to keep a dog in a town unless he can show that he is able to make provision for the dog's efficient sanitary care. Since the public conscience in the matter appears to be thoroughly callous, the proper thing to do would be to impose an additional yearly tax, say, of £2, on every dog kept in a town." I sincerely hope that Rochester will take notice of these wise words, and that in due course other cities will follow suit.

Dogs not Under Control. In the *Evening News* of May 5th there appeared an article on the **Dogs and the Food Question.** "Cats of London," in which it is stated that "There is enough meat wasted on dogs every day in London to feed thousands of poor people. Big dogs costing seven and eight shillings a week to keep are owned by people who are helping to keep up the price of

food by keeping these big animals often when their duty points towards helping human beings to have enough to eat. In London alone there are nearly 180,000 dogs, and in Greater London, which includes the County of London, there are more than a quarter of a million, all needing food every day, all helping to keep up the prices of food." It is extraordinary that these facts are not faced by the authorities who are for ever preaching economy. A very little legislative or administrative attention would soon put an end to such a scandalous state of matters.

Cats and the Milk Supply. On the question of cats themselves, the article is instructive. There are, it seems, no available statistics relating to cats, but the writer estimates the number in London and

Greater London to be about 750,000. If half of these are given a saucer of milk a day, which is a moderate estimate, "they would lap up 12,000 gallons of milk a day, costing £1,200 a day, or over £8,000 a week. These 12,000 gallons of milk would give a pint of vital food to over 90,000 poor children; they would ensure more than a quart of milk each day for every necessitous child now being fed by the London County Council." The plea in favour of the cat which I quoted in a recent issue—namely, that it keeps down rats and mice, would seem to be more than counter-balanced by these figures. After all, it ought to be possible to limit these rodents, and even entirely to exterminate them, by some means less costly than the keeping of cats, many of which are indeed too pampered by milk and other delicacies to trouble about hunting their natural prey. But the most serious indictment which is brought against the cat is not its extravagance, but its disease-carrying propensities. It has been said many a time and oft that diphtheria had been traced to cats, but the evidence on this point has never been conclusive. It seems that bacteriological investigations have recently shown that cats really are frequent "carriers" of the Klebs-Loeffler bacillus and that consequently the most "harmless, necessary" domestic pet may be a source of very grave danger to the inmates of the nursery. That cats, like all domestic animals, disseminate almost every variety of "ring-worm" is well known. There is thus good reason for the suggestion that these animals should be registered and taxed.

SINAPIS.

MISS ELIZABETH SIMPKINS, of Brighton, bequeathed £5,000 to the Sussex County Hospital, as a further memorial to her brother; £1,000 each to the Royal Alexandra Hospital for Children, Brighton; Brighton and Hove Branch of the Surgical Aid Society; Throat and Ear Hospital, Brighton; Eye Hospital, Brighton; Asylum for the Blind, Brighton; and the Asylum for Deaf and Dumb Children, Brighton; £500 to the Crèche, Brighton.

MR. THOMAS TAYLOR, of Blackpool, left £1,000 each to the Children's Hospital, Pendlebury, and the Ashton Infirmary, and a further £1,000 to the last-named institution, if the residuary estate will permit, for the endowment of children's cots in memory of his brother and sister.

CURRENT TOPICS.

The Illicit Use of Cocaine.

THE need for reform in medical jurisprudence is strikingly illustrated in connection with the laws governing the acquisition and sale of cocaine. A case brought up at Bow Street Police Court of a man who was arrested in Leicester Square while offering for sale pill-boxes each containing one and a half grains of cocaine had to be dismissed because it did not come under the rules of unlawful possession, and because no actual sale had been proved. Counsel stated that "the prisoner was one of a number of men who were engaged in a most wicked and dangerous traffic with cocaine in the West End," also that "the use of cocaine was now largely on the increase among prostitutes and some soldiers, and the drug was being illicitly imported into this country." The only effort at remedy so far reported is an order under the Defence of the Realm Regulations, which prohibits the sale of cocaine, opium, and some other drugs to any members of his Majesty's Forces, unless ordered by a practitioner in a written prescription and marked "Not to be repeated." Some months ago we drew attention to the grave danger to which foolish people were exposing friends at the front by giving them supplies of morphia and other such drugs. That the evils and prevalence of this drug habit are recognised elsewhere is very evident from the editorial of a recent number of the *Canadian Journal of Medicine and Surgery*. The Editor, while recording the third case of a medical practitioner convicted for the illicit sale of cocaine, puts forward a plea that any practitioner so convicted should be deprived of his licence for the first offence. Other preventive and remedial measures advocated are:—(1) The forcible arrest and detention of the drug victims for the purpose of treatment; (2) public education by means of lectures and literature, as well as by the teaching in schools; (3) complete Government control of the importation and sale of the drug.

The College of Nursing, Limited.

MR. ARTHUR STANLEY, having failed to make any impression on the nursing organisations in his endeavours to lure them into his "College of Nursing, Limited," is now attempting to inveigle the nursing schools into his scheme. He has issued a letter to the heads of some two hundred of the nursing schools of the United Kingdom in which he invites them to nominate persons for seats on his Consultative Board. The Consultative Board, however, is not to possess any powers beyond the right to express opinions which the Council of the College may or may not accept. However, the acceptance of Mr. Stanley's invitation does not give the nominee of a nursing school the right to sit on the Consultative Board. Mr. Stanley reserves for the Council the right to select from all the nominations submitted those who are to constitute the Consultative Board. One would think that, having been thus selected by the Council and having no powers, the Consultative Board would be sufficiently harmless, but Mr. Stanley has got another safeguard to prevent any possibility of its becoming troublesome. We quote his own words: "For facilitating the work of the Consultative Board, the Council has formed a Consultative Committee, with power to add to its numbers from amongst persons appointed on the Board, so that business may be put before the full Board in such a way as not to make too great claims upon the time of its members, many of whom can only give occasional attendance in London." To put it

plainly, the Executive Committee of the Board is elected by the Council, and it may or may not contain a single member of the Board. We hardly think that the authorities of the nursing schools are to be fooled by such an impudent proposal as this. They are asked to commit themselves to the support of Mr. Stanley's scheme without being given the slightest influence in moulding it either in its formation or its development.

Reports of Factory Surgeons.

ONE of the most inept of the recommendations in the Report of the Committee on Retrenchment in the Public Expenditure is that the inquiries and reports of certifying surgeons on accidents occurring in factories and workshops should be dispensed with, since such reports are alleged to be of little value and to entail duplicates of reports of inspectors. It is to be noted that the total sum involved is only £12,500 a year, and it is, perhaps, typical of the official mind that such a beggarly item should be selected for economy. We have made a computation, however, and we find that the sum to be saved by the proposed economy would pay for three minutes and thirty-six seconds of the war! The function of the Committee on Retrenchment was, however, to deal with economies which might be practised "without detriment to the interests of the State," and there are good reasons for holding that this particular economy would be highly detrimental. The Incorporated Association of Certifying Factory Surgeons has dealt with the proposal in all its aspects in a temperate and logical memorandum which will well repay study. We have not space here to recapitulate the arguments, but they appear to us to be cogent in showing that there is not a true duplication in the reports of the surgeon and of the inspector, that the cessation of the surgeon's reports would deprive the workman of certain valuable safeguards, and that the technical knowledge of the surgeon is frequently the determining factor in assessing the correct causation of an accident. While arguing against the total abolition of the surgeon's reports, the Association admits that certain economies are practicable.

The Ætiology of Common Colds.

CONTROVERSY on the subject of the ætiology of colds has waged a lengthy warfare. The common theory of bacterial infection has been held up by the investigations of Kruse. He discovered that the nasal secretion of a person suffering from coryza when passed through a Berkefeld filter, and therefore deprived of bacteria, was capable of inducing a similar cold in a healthy subject if brought into contact with the nasal mucous membrane. Yet he was unable to demonstrate the presence of living organisms in this filtrate by any bacteriological methods, and he therefore decided to class the organism among the filterable viruses. His results have been confirmed by Captain G. Foster, whose further investigations are described in a paper published in a recent number of the *Journal of the American Medical Association*. Following the methods used by Noguchi and Flexner in the cultivation of the filterable virus of rabies and of that of poliomyelitis, Foster succeeded in obtaining microscopic evidence of the growth of the virus of colds in a culture made from the filtrate in tissue-ascitic fluid. Subcultures were made to the fourth generation, and in each of these the visible changes were more marked than in the original culture tube. Their virulence was directly proved, for material taken from these subculture tubes, filtered and diluted so that the ultimate mixture contained but 1 part in 90,000 of the original nasal secretion, was

dropped into the nostrils of eleven healthy men, who all became ill with acute colds within forty-eight hours. We will have to mitigate the contempt with which we treat our common colds if their cause may thus be classed with the causes of such obscure conditions as rabies and poliomyelitis. In this connection, therefore, the work of Captain Foster may prove to be of the greatest value. Other investigators have come to the conclusion that common cold may be due to any one of several different organisms, and the results of vaccine therapy support this view.

Meningococci Carriers.

DR. BERZANCON, of the Paris Faculty of Medicine, in a recent communication remarks that most frequently the germ carrier is quite healthy, in some cases there is catarrh of the rhinopharynx, and in others there are slight symptoms of meningitis. The transmission of meningococci from healthy children or soldiers explains why contagion may take place unobserved. A French Ministerial order prescribes the bacteriological examination of the rhino-pharyngeal mucus of the persons living in close contact with the patient when a case of cerebro-spinal meningitis is notified. In barracks, any men found to be germ carriers are immediately isolated. The treatment applied to germ carriers consists in inhalations with iodine (Vincent), painting the pharynx with iodine and glycerine (1 in 30), gargling with peroxide of hydrogen (1 in 10). In children, he remarks, milder antiseptics must be used.

Birkenhead School Clinics.

THE annual report of the School Medical Officer of Birkenhead, Dr. Robert S. Marsden, states that during 1915 there was an increasing demand for remedial work and treatment at the school clinic. There was a large increase in the treatment given for diseases of the ear. Dr. Marsden points out that, unfortunately, in these cases parents do not seem to co-operate as they should by seeing that affected children attend regularly at school clinic, with the result that recovery is often seriously retarded. In regard to defective vision, the Board of Education sanctioned the expenditure by the committee of a sum not exceeding £50 on the provision of inexpensive spectacles to those children whose eyesight is found defective on medical inspection, and in whose cases the committee, after inquiry, are satisfied the parents are unable to provide the whole or part of the cost of the spectacles. During the year 144 pairs of spectacles have been obtained, of which 134 pairs have been obtained with the help of the committee at a cost of £25 5s. Owing to the present conditions, whereby hospital staffs have been either depleted or otherwise engaged on war work, diseases of the eye and ear have been given special treatment.

The clothing and footgear of the children have, on the whole, been found to be fair, but there is much room for improvement. Much stress has been laid on the question of footgear in dealing with the parents, and suggestions made as to the type to be worn—that the clogs are warmer, more impervious to damp, and more economical to use. The same clothing is used winter and summer, and the use of the overcoat is not general. Many children on a wet day come to school without them. These children sit down in school "steaming," and many illnesses may be traced to this practice.

Taken on the whole, nutrition has been average, though in many cases it has been found sub-normal. The opinion is expressed that unsuitability of food is more to blame than insufficiency. Dr. Marsden emphasises the fact that, not only the filling of the

child should be considered: it is as important that the proper proportion of nutritive material should be given to supply the demands of the various growing tissues. He affirms that the defective condition of the teeth is undoubtedly the most prevalent fault in the condition of school children, and calls for very urgent treatment. A complete set of perfect teeth is rarely seen.

The London and Counties Medical Protection Society, Ltd.

We have perused with interest the Annual Report (for 1915) of the Council of the above Society. Since its inception, in 1892, the Society has done excellent work for its members, and indirectly for the profession in general, and we are glad to note the statement that in 1915, notwithstanding the special anxieties of the year, the results have been quite satisfactory, and the steady progress made by the Society, since it was founded nearly twenty-five year ago, continues unbroken.

During the past year 560 members asked advice and assistance, and in the great majority of cases, satisfactory results were obtained without recourse to litigation, and the results of the cases in which litigation was needed were also satisfactory.

Details of the special cases are embodied in the report.

Reference is made to the great loss the Society sustained in 1915 by the death of its President, Dr. G. A. Heron, and the Society also lost two highly-valued Vice-Presidents—Mr. Edmund Owen and Dr. Robert Boxall. The war has taken its toll from the members of the Society, several having lost their lives on the field of battle in the service of their country.

Sir John Rose Bradford has been elected President of the Society in succession to the late Dr. Heron.

We are glad to learn that the financial position is exceedingly satisfactory, and that there is a considerable increase in the funds of the Society. Membership only involves an entrance fee of 10s. with an annual subscription of 20s. Every medical man should insure himself against many of the risks of medical practice by joining an association with objects such as those of the London and Counties Medical Protection Society.

PERSONAL.

HER MAJESTY THE QUEEN has consented to open the New South London Hospital for Women, Clapham Common, on July 14th. The cost of the actual building has been entirely defrayed by generous friends, but an appeal is being made for funds to equip and maintain it. The hospital will be run and staffed entirely by women.

THE new Director of Recruiting, Brigadier-General A. C. Geddes, graduated M.B. at Edinburgh in 1903. He was gazetted on December 9th, 1915, as a Deputy Assistant Adjutant-General.

THE Royal College of Physicians of Edinburgh has resolved to offer its diploma of membership to Major H. E. Priestley, Captain A. C. Vidal, and Captain J. L. Lauder, in appreciation of their conduct as physicians at Wittenberg.

DR. ANDREW CAMPBELL, Edinburgh, has been appointed resident surgical officer of the Birmingham and Midland Eye Hospital. Dr. Campbell was educated at the Grammar School, Aberdeen, and Edinburgh University, where he graduated M.B., Ch.B., in 1910, and D.P.H. in 1913. For the last three years he has worked under Dr. Logan Turner in the Ear, Nose and Throat Ward, Royal Infirmary, Edinburgh.

ORIGINAL PAPERS.

THE TREATMENT OF BACKWARD DISPLACEMENTS OF THE UTERUS.*

By FREDERICK J. McCANN, M.D.Edin., F.R.C.S.Eng.

Surgeon to the Samaritan Free Hospital for Women, London, N.W.

(Concluded from page 422.)

TREATMENT OF BACKWARD DISPLACEMENTS IN PAROUS WOMEN.

BACKWARD displacements frequently develop after a confinement or abortion, when, in consequence of the supports being slackened, the enlarged uterus falls backwards. Here, however, the pessary has its most useful application, and if worn for six months a cure will result. This being so, it is obvious that preventive treatment is of paramount importance in order to help in reducing the enormous number of women so afflicted.

The best method of so doing is to make it a rule that every woman should be examined from four to six weeks after labour in order to determine the state of the uterus and adnexæ, the vaginal walls and perineum. If this were done it would diminish markedly the number of women who are suffering from prolapse and displacements. Treatment could at once be applied to the uterus, vaginal walls and perineum before marked changes had been produced. Unfortunately, women are anxious to get rid of the doctor as soon after the confinement as possible, and a visit for further investigation might be resented. But after all, the doctors should be the guide of their patients in this regard, and must educate them to appreciate the value of such an investigation. Unless this is done we shall continue to blunder along in the same old way, doing nothing to prevent what is easily preventable.

It has been recently asserted, but with limited proof, that early rising after childbirth tends to prevent backward displacements. If this be so it will be a great gain, but at present I am still in favour of rest in bed after labour, but during this period exercises and later massage may be usefully employed. Massage is of great benefit when the abdominal muscles are poorly developed, or when the abdominal walls have been overstretched. A woman who has suffered from a displacement previous to her pregnancy should have a longer period of rest after her confinement.

When a chronic displacement is encountered in a parous woman, it is essential to make sure that there is no defect in the perineum or vaginal walls, no chronic metritis, or inflammation of the adnexæ. All these must be taken into account before deciding upon the appropriate treatment. No "cases" require greater experience in deciding on what to do and how to do it, and the ability in selecting the correct treatment stamps the master.

It will be found that apart from those examples following a labour or abortion, nearly all the chronic types will require some form of surgical treatment. The part or parts of the suspensory mechanism which are at fault have to be determined and suitably remedied. There is no one operation or one treatment for this condition. Indeed, one must view with considerable mistrust the surgical judgment of any operator who within a limited period of time can furnish a long list of patients treated by one operation. One operator,

after an experience of nearly 700 cases, came to the conclusion that his method was radically wrong. An honest confession, no doubt, but what a slaughter of the innocents!

When I tell you that over 100 operations have been devised for the treatment of backward displacements, each of which according to the originator is the best, I may be pardoned for dwelling upon this theme. A peculiar type of egotism seems to seize those who originate such operations, for they at once convince themselves that their operation yields the best results and is universally applicable.

My own experience leads me to the conclusion that as all the cases are different so the treatment must vary according to the extent and character of the pathological changes encountered. At the same time there are certain broad principles which should govern the treatment. Foremost amongst these is the age of the patient. Is she of childbearing age, or has her menstruation ceased? If of childbearing age, the possibility of further pregnancy should be remembered, and any treatment tending to cause interference therewith should be avoided. If past the climacteric, the pregnancy factor is eliminated. Again, surgical treatment should aim at restoring as far as possible the normal anatomical relationships, and not substituting one deformity for another. Further, the cure should be such that it can withstand the strain of future pregnancies.

To find in a parous woman a backward displacement without any other complication is rare; generally parturition has left its mark on the body or cervix of the uterus, the vaginal walls and the perineum, or, in addition, on the appendages, pelvic peritoneum and cellular tissue. The abdominal walls, too, may have suffered, remaining overstretched, thin and atrophic, whilst a general ptosis of the abdominal viscera may be an additional complication.

Let us see, then, what treatment should be adopted during the childbearing period—(1) when the uterus is replaceable, and (2) when it is fixed:—

(1) *When the Uterus is Replaceable.*—(a) The uterus displaced backwards without relaxation of the vaginal walls and the perineum sound. Here a trial may be given to pessary treatment for six to twelve months, and if it fails, surgical treatment should be advised. Such cases, however, are not common.

(b) The uterus displaced backwards with slight descent, relaxed vaginal walls and deficient perineum. Here a repair of the vaginal walls and perineum should be done, and as a result the backward displacement may right itself.

(c) Uterus displaced backwards, slight descent, cervix fissured and thickened, relaxed vaginal walls and perineal deficiency. In addition to repairing the vaginal walls and perineum, the condition of the cervix requires attention, for if it remains enlarged it tends to act as a dilating wedge.

Fissures should be repaired, and if necessary a triangular piece excised from the anterior and posterior cervical walls, followed by accurate suture-

* A paper read before the Harveian Society, April 13, 1916.

This operation preserves the continuity of the canal, and is preferable to amputation of the cervix in the parous woman.

(d) Uterus displaced backwards, relaxed vaginal walls, perineal deficiency, abdominal walls thin and atrophic, with visceral ptosis. The vaginal walls and perineum should be repaired and massage exercises, etc., should be recommended. For the poorer classes an abdominal belt will be found to be of great assistance, whilst for those who can afford them properly fitting corsets should be obtained.

(e) Uterus displaced backwards and enlarged, causing profuse and irregular menstruation, vaginal walls relaxed, perineum deficient. In addition to vaginal and perineal repair, the operation of curetting is indicated.

(f) Uterus displaced backwards, accompanied by thickening in the cellular tissue laterally and posteriorly. Treatment should here be directed to the improvement of the chronic inflammatory deposits. Rest, counter-irritation, glycerine tampons, etc., should be tried. In the absence of tubal complication such cases are not suitable for an abdominal operation.

(g) Uterus displaced backwards, with a greater degree of descent. Vaginal walls not relaxed and perineum sound. An abdominal operation to remedy the uterine displacement and descent is indicated. Such cases are also not common.

(h) Uterus displaced backwards, with a greater degree of descent, relaxation of the vaginal walls and perineal deficiency. An abdominal operation will be required in addition to the vaginal and perineal repair. In estimating the amount of descent of the uterus or vaginal walls, examination in the supine position is unsatisfactory unless the woman is instructed to bear down, which will give a better idea of what the conditions are when she is standing erect.

(2) *When the uterus is fixed.*—When the uterus is displaced backwards and fixed the displacement is most frequently the result of a localised peritonitis, infective in character. In nulliparæ gonococcal infection is the most common cause, whilst in parous women there may be, in addition to the gonococcus, infection from other organisms following abortion or full time labour.

Gonococcal infection leads to an adhesive peritonitis, which tends to persist. The effects produced are seen to be most marked in and around the appendages, and thus it comes to pass that partial mobility of the uterus is not infrequent, although it cannot be replaced in its normal position.

The best treatment for partially mobile and for fixed uteri is to open the abdomen and deal with the complications which are found. It is advised that forcible replacement should be practised with or without the aid of anæsthesia. This brutal method should be definitely abandoned, for who can tell how much internal damage has been done? Through an abdominal incision the diseased parts can be inspected, and by the employment of conservative surgery the function of the appendages may be completely restored. The time element is of supreme importance, for the more chronic the disease the more likely it is to be attended with destructive effects.

ABDOMINAL AND VAGINAL OPERATIONS FOR BACKWARD DISPLACEMENT.

Let us now consider the operations which may be advised and practised for the cure of backward displacements.

Abdominal Operations.—For maintaining the uterus in a forward position a variety of procedures may be adopted. The uterus may be stitched to

the abdominal wall or the round ligaments folded within the abdomen or sutured to the abdominal wall or drawn into the wall or drawn backwards through a hole in the broad ligaments or folded back over the uterine cornua. The broad ligaments also may be folded in front of the uterus or behind the uterus. Different methods may be usefully employed according to the necessities of the situation; much use, however, can be made of the round ligaments to cover pedicles and to keep the uterus forwards where it has been necessary to remove some portion of the appendages. It is necessary to maintain the uterus in an anterior position after separating adhesions, etc., for unless this is done it will fall back again and the old symptoms will return.

It has often been asserted that these operations should be concluded by fixing the uterus to the abdominal wall. Such statements can only be made by those who have had little experience, for in the presence of inflammatory exudation it is often impossible to fix the uterus to the abdominal wall, and if it is done, the fixation will either soon stretch and give way or cause great suffering from the tension. It is here that the different methods of folding the round ligaments find a useful application.

For uncomplicated displacements with little or no descent, what is known as the "sling operation"—*i.e.*, pulling the round ligaments backwards through a hole in the broad ligament under the utero-ovarian ligament and fixing them to one another and to the back of the uterus. This operation should not be done in the presence of varicose veins in the broad ligament—for a number of instances of iliac thrombosis have been recorded following this operation. Moreover, it does not produce sufficient elevation of the uterus, should there be descent. In appropriate cases, however, I have found it a satisfactory procedure.

Another method I have employed for several years is fixation of the round ligaments to the lower part of the abdominal wall, just above the bladder, by means of buried silkworm gut sutures.

Technique.—This operation is done either by a transverse or a vertical incision.

In order that the transverse incision may be completely hidden by the vulvar hairs, I have employed the following modification. The skin is stretched in an upward direction by means of three pairs of Kocher forceps, one median and two lateral, applied to the transverse line on the skin of the abdominal wall, which is usually found about one inch above the symphysis pubis. The transverse incision is then made midway between the points of the forceps and the symphysis pubis, so that when the incision is sutured it lies across the Mons Veneris and becomes completely hidden by the growth of hair. The transverse incision need only extend as far as the position of the superficial epigastric vessels, which need not be divided.

After division of the skin and fat they are further separated from the aponeurosis in an upward direction until sufficient space is obtained to divide the aponeurosis in the middle line. The muscles are next separated (not cut) and the peritoneum exposed and opened. The uterus and appendages are examined, and if the latter are normal, the round ligament of one side is seized close to its uterine attachment with a pair of long Kocher forceps. A curved needle armed with silkworm gut is then passed through the aponeurosis, muscle and peritoneum, then under the round ligament close to the uterus and back again through peritoneum, muscle and aponeurosis. The needle is passed about one inch from the incision at its lower part close to the top of the bladder, which can be both seen and felt, and is a much better guide than any definite

measurement by inches from the symphysis pubis which seems customary in describing similar operations. The round ligament of the opposite side is treated in like manner, and when the silkworm gut is held taut on either side the uterus is suspended and anteverted. The peritoneum, muscles, and aponeurosis are united in the middle line, and then the silkworm gut is tied on each side. The tying must not be too tight and the threads must be so cut that they do not cause subsequent pricking.

If thought desirable, two or three catgut sutures uniting the round ligaments to the peritoneum may be inserted on either side to reinforce the silkworm gut.

This operation is simple, safe and satisfactory.

It leaves the uterus in good position, so that on examining some time after the operation it is difficult to tell what had been done. It does not interfere with subsequent pregnancy or labour, and it is an operation I frequently employ in the treatment of sterility. One of my patients, operated on after four years of sterile married life, has had two children born at the full time without difficulty, and her doctor informs me that her uterus is still in good position.

The possibility of intestinal obstruction from intestine being constricted under the attached ligaments might be urged against this operation. I am not aware that it has ever happened to any of my patients, and I should imagine that it is highly improbable that it ever will, if the operation be done in the manner suggested. I believe the dangers from obstruction are exaggerated, and when it does occur it is in all probability due to faulty technique.

Still striving after perfection, I tried another method.

A transverse incision is also used, and at its outer extremity I made a small incision into the aponeurosis, then separating the muscle fibres, a pair of Kocher forceps is used to push inwards the peritoneum. The latter is then snipped with scissors and the forceps pushed on through the hole and made to seize the round ligament towards its outer extremity. A loop of the ligament is then pulled through the track of the forceps and fixed by sutures on to the anterior surface of the aponeurosis.

The slit in the aponeurosis should not be too small lest the ligament be constricted, and for the same reason the sutures require to be carefully applied. The ligament is best fixed by three sutures; one at each side fixes it at the opening, and also unites the aponeurosis, and one at the extremity of the loop, or the loop may be pushed under the aponeurosis, a pair of forceps being used to separate the latter from the muscle, a catgut stitch closing the aperture.

The same procedure is then done on the other side, and the median and transverse incisions closed. Before closing the incision accurate hæmostasis should be obtained. Three silkworm gut sutures are passed, one mesial and two lateral; these should take a grip of the aponeurosis as well as the fat and skin. A buried suture of catgut is inserted to approximate the fat and aponeurosis and destroy dead spaces. The silkworm gut sutures are then tied over small pieces of indiarubber tubing after the skin edges have been approximated by Michel clips.

This operation leaves the uterus movable with no band or bands inside the abdomen around which the wandering intestine may inadvertently slip, and it does not interfere with subsequent pregnancy or labour.

I have employed this method for some years but have not put it on record until I was able to

apply the best test of all—viz., the time test. Half-baked produce irritates the student of literature and disappoints the practitioner.

I do not intend to fight the question of priority, but the method was original as far as I was concerned. I always thought that burrowing between the layers of the abdominal wall, a principle employed by so many operators, was not an ideal method.

An objection which may be lodged against this operation is that the cervix may be tilted slightly forwards, but this could be remedied by shortening the utero-sacral ligaments, although I have not yet adopted this additional modification. Both these methods of round ligament fixation will be found suitable and should be selected according to the indications present.

The Alexander Adams operation of shortening the round ligament by opening the inguinal canal need only be mentioned, as it was a step towards the production of improved methods. It has the great disadvantage that the condition of the appendages cannot be inspected. It is impossible to tell by examination if the appendages are normal, however great the ability of the examiner may be. The great frequency of adnexal complications is one of the important lessons I have learned from my operative work, and not the least in importance is the fact that, although the uterus may be movable and replaceable in a position of anteversion, the tubal extremities may be sealed from the result of old inflammation, thus rendering the woman sterile.

The old "fear of the peritoneal cavity" having departed, there is no further need for extra-peritoneal operations.

VAGINAL OPERATIONS.

Vaginal Fixation.—In 1902 (a) I described a method of Vaginal Fixation which I had carried out successfully in a series of cases, the details of the technique being somewhat different from those originally suggested.

Briefly the fixation did not extend above the lower part of the uterine body, thus permitting the uterus to enlarge during pregnancy. This operation does not interfere with the subsequent course of pregnancy or labour, and is quite different from the complete vaginal fixation of the uterus which from its very inception must have been condemned by anyone possessing surgical nous.

I still believe vaginal fixation performed in the manner suggested to be a good operation, and as an adjunct to other vaginal operations, it may be usefully employed.

The indications for its use are, however, definitely limited, and it is not applicable where there is much descent complicating a backward displacement, or when the uterus is fixed.

Vaginal fixation of the round ligaments is another operation which is being employed, but of this I have no experience. It is obviously unsuitable where there is uterine descent.

The disadvantage of these operations is that you do not have the opportunity of inspecting the pelvic contents and of being enabled to deal with any complications which are present.

BACKWARD DISPLACEMENTS AFTER THE MENOPAUSE.

If the uterus be small and atrophic no treatment is necessary, for it will be found that under these circumstances the displacement does not cause any trouble.

If the uterus be still large, and the other indications point to the necessity for an abdominal operation, a thorough fixation of the uterus can be done, for here the question of future pregnancy

(a) *British Medical Journal.*

does not arise. Otherwise the same rules should guide the treatment as are applicable to women in the child-bearing period.

BACKWARD DISPLACEMENTS IN ASSOCIATION WITH UTERINE AND OVARIAN TUMOURS.

A backward displacement of the uterus may result from the presence of a pelvic tumour pushing the uterus backwards.

When the tumour is removed the uterus may still fall backwards, and here one of the methods of plicating the round ligament will be found of service, or the round ligament of the corresponding side may be used to cover the pedicle (if an ovarian tumour has been removed) and at the same time help to keep the uterus forward.

A small fibroid embedded in the posterior or anterior uterine wall may easily be mistaken for an enlarged retroverted uterus. Such fibroids should be enucleated and the resulting cavity closed by suture. If desirable, this operation should be followed by another on the round ligaments.

Twelve months after myomectomy and uterine suspension by the round ligaments one of my patients gave birth to a healthy, full-time child without difficulty.

BACKWARD DISPLACEMENT OF THE GRAVID UTERUS.

When the gravid uterus is displaced backwards it may right itself, and even if accompanied by retention of urine, rest in bed and the regular use of the catheter to make sure the bladder is emptied, will frequently effect a cure. As all methods of replacement are apt to be followed by abortion, the greatest gentleness must be exercised should it become necessary to replace the uterus.

The uterus may, however, be fixed backwards by adhesions, and here it may be necessary to open the abdomen and free the adhesions. I have done this operation on two occasions.

One patient went to term and was successfully delivered; the other aborted four weeks after the operation.

If, however, fixed backward displacements are treated on the lines already indicated the occasion for this operation will not arise.

In conclusion, although I feel that the subject has not yet been settled, I trust I have said enough to urge the importance of a broader outlook in the treatment of backward displacement of the uterus.

A CASE OF ECTOPIA VESICÆ IN AN ADULT TREATED BY TRANSPLANTATION OF THE URETERS.*

By HENRY STOKES, M.D., F.R.C.S.I.,
Surgeon to the Meath Hospital, Dublin.

IN presenting the following case it is not my intention to lay stress on the causes of ectopia vesicæ, or to give any account of the numerous operations which have been devised for the treatment. I simply refer any interested to the papers of Mr. Arthur Ball and Mr. Kennedy which are found in the *Transactions* of this Academy, and also to the paper by Buchanan in the *Surgery, Gynaecology, and Obstetrics* of the year 1909.

The patient was admitted to hospital on October 25th, 1915, æt. 26, but having the appearance of about 17, although healthy and well developed. The history, as related by his mother, was that since birth urine had been dribbling from the abdominal wall.

When born there had been difficulty in determining the sex; however, he was called a male, and brought up as such. At the age of ten

a doctor in the country attempted, without success, to cure the condition by some type of flap operation. About this time Sir Kendal Franks saw the patient; what his views were on the case are not known. No further treatment was undertaken, and the patient lived a life of what must have been misery. Using 30 to 40 towels in the day, and at night lying in a pool of urine, he survived for 26 years.

On admission to hospital, I, for the first time, saw the patient in the presence of a class of students. The condition, as far as the bladder was concerned, was typical of ectopia vesicæ—that is to say, there was an area of chronically inflamed mucous membrane, measuring about 2½ inches by 2 inches, where the symphysis pubis should have been. There was no umbilicus, and, as there were numerous scars from the old operation, I could not be quite sure that one of these did not represent the umbilicus. The pubic bones were widely separated. On examining the external genital organs I was perplexed. For 26 years the patient had been considered a male; he was lying in a male ward. There was present a projection about three-quarters of an inch long below the area of mucous membrane; this projection was cleft. Further back, at each side, were two bulging masses; all these seemed to tally with a cleft rudimentary penis and a cleft scrotum. Yet there was something suspicious about the pubic hair.

I asked Mr. Ball to see the case with me next day, knowing of his previous gratifying success with a similar condition. Mr. Ball regarded the patient as a female, and well-developed female breasts coupled with a history of regular menstruation, left little doubt. Dr. Kidd kindly examined the case for me and was able to palpate a uterus and demonstrate a canal leading thereto.

The fact that the patient was a fully-developed female of twenty-six years naturally added difficulties to the operation. A search through literature only revealed one careful account of a somewhat similar case, in which anatomical peculiarities were shown of a very discouraging nature. A careful dissection of the region only served to frighten me on account of the large, thin-walled veins lying along the pelvis wall, while I could not demonstrate any visible supply to the lower ends of the ureters.

Operation.—On October 30th, 1915, with the assistance of Dr. Kidd and Mr. Ball, I isolated each ureter, with a button of mucous membrane attached, for the distance of about three inches. Then a transverse incision was made, and the uterus, which was normally developed, was removed, the peritoneum being sutured over Douglas' pouch. With one finger in the peritoneal cavity, a curved forceps was introduced into the rectum and with some difficulty pushed out through the abdominal wound. The track made was extra-peritoneal. The rosettes of mucous membrane were, in succession, pulled into the rectum, where they hung freely. The abdominal wound was then closed after the patch of mucous membrane had been removed.

For three weeks the patient did unexpectedly well, only having passed water per rectum involuntarily on two or three occasions, and being able to keep herself quite dry both night and day. On the twenty-second day she lost control over her rectum, and passed urine mixed with blood and mucus frequently. For five days this continued, and was accompanied by fever with a temperature rising to 101°. On the twenty-seventh day I saw a dead gangrenous mass hanging out of the anus. Gentle pressure removed a dead rosette with one inch of ureter attached. From that time onwards urine began to trickle from the vagina. This condition persisted, the patient losing ground slowly.

* Read before the Section of Surgery of the Royal Academy of Medicine in Ireland.

Mr. Ball again saw her with me, and an attempt which proved futile was made to find out which ureter was leaking.

On December 18th I operated a second time, with a view to anastomosing the leaking ureter into the colon. I believed the right ureter to be at fault, and operated through an incision in the loin. The peritoneum was peeled forward, but no ureter could be found. The ovarian vessels were exposed as were the vena cava and aorta.

As it was essential to locate the ureter, I enlarged the incision downwards towards the fistula, and twice thought I had found the ureter. The first time I dissected out a very well developed round ligament, and on the second occasion I found the obliterated hypogastric artery leading to the anterior abdominal wall. These structures were both divided, and off the latter were seen small branches representing the superior and middle vesical arteries.

As I still could not define a ureter, I prolonged the incision upwards to expose the kidney. The kidney was enlarged, and had a very short pedicle which was bound down to the vena cava and aorta. From the hilum of the kidney a thick band ran down in the middle line across the bifurcation of the aorta, along the centre of the sacrum, and ended in the stump of the amputated uterus. I had seen this structure earlier in the operation, but as I could feel the pulsations of the aorta through it I did not believe it was the ureter. However, now I knew that it was.

As it was too dangerous to attempt to separate the inflamed and dilated ureter from the vena cava, and as even if I had done so I doubt if I could have transplanted it, I removed the kidney, leaving the ureter alone. As the peritoneum had been opened lower down, I passed my finger across the middle line and felt the left ureter in its normal situation. It was apparently normal to touch. The large wound was partly closed and drains left in. For some days the patient did well, but then symptoms of uræmia appeared, and the patient died on December 29th.

At the autopsy the left ureter with its rosette of bladder wall was found fixed in the rectum with no septic changes at the point of junction. The right ureter was found leading into the vagina. An abscess cavity containing about one ounce of pus lay at the bottom of Douglas' pouch. The left kidney showed pyelo-nephritis. Microscopical slides of the transplanted papilla showed that all the original bladder epithelium had disappeared, it having been replaced by scar tissue.

The anatomy of the internal organs was interesting, as apart from the disturbance due to separation of the pubic bones and to the absence of the bladder no abnormalities were found, unless we regard the internal displacement of the right ureter on to the surface of the vena cava as not being due to the dragging caused by the transplantation of the ureter at the first operation.

The separation of the anterior superior iliac spines was 10.125 c.m., the pubic crests 6.25 c.m. The depth of the pelvis from pubis to sacrum was 6.25 c.m.

The fatal outcome of the case was, I believe, due to infection of the transplanted part of the right ureter, causing an abscess to form outside the rectum and subsequent sloughing of the transplanted portion eventually leading on to ascending infection of both kidneys.

AMONG other gifts, ten extra motor ambulances for hospitals in India at a cost of £7,000 are being supplied by the St. John Ambulance Association.

EYE-FUNCTION AND LIGHT.

By P. W. COBB, M.D.,

Cleveland.

It is readily to be seen that the problems relating to light and vision naturally divide themselves into two groups. They may be of interest on account of demonstrable anatomical lesions as a result of the incidence of radiation upon the tissues; or on account of disturbances set up originally in the sensory apparatus of the eye by adverse conditions of stimulation. It is the latter phase of the general question which is the subject of the present paper, and to make clear exactly what is meant it may be well to mention one or two facts of physiological optics (a).

One of these is the fact of adaptation. The least visible stimulus on going directly from a bright environment into a dark room has been shown to be from one thousand to several thousand times as great as the least visible after an hour's stay in the dark. The result of the sudden admission of much light into the eye in this dark-adapted condition is a blinding dazzle and pain, which rapidly subside; and in the course of perhaps twenty minutes the eye regains its former light-adapted state.

Contrast is also of interest here. It is a notable fact that in looking into the interior of a house from out-of-doors it is difficult or impossible to distinguish the objects within, while in the opposite case, looking out of a small window from the interior, such difficulty is not ordinarily met. It may, however, be experimentally demonstrated, as will be shown further on; and it is to be pointed out here that vision of a small bright field in relatively dark and extensive surroundings is accompanied by a vague discomfort, which for the want of a better word we will call *glare*, rather than by any material difficulty in the actual resolving of form—very much as in the case of a dark-adapted eye flooded with light. Indeed the two cases might without constraint be classed respectively as simultaneous and successive contrast.

A third point is the application to vision of Weber's law. This states (for all the senses) that two stimuli, to be just appreciably different, must be different in physical magnitude by an amount which for any given sense and mode of experimentation is a constant fraction of the absolute magnitude, irrespective of what the latter may be. That is to say, that the two stimuli in question must bear a constant ratio to each other. As above stated, the law is perhaps somewhat amplified over its original form. Its applicability to vision has been verified for a wide stimulus range, and a rough exemplification of it is in the fact that the objects in a room look the same whatever the absolute intensity of illumination may be. Any two objects reflect equal fractions of the light falling upon them, and hence always send light to the eye in the same ratio, and in this concrete case the law will also be found to hold for a wide range, breaking down most evidently at very low illuminations.

In view of the foregoing a few remarks may be made by way of orientation in the problem in question:

In order that they may be seen, objects or characters must present differences in brightness from that of the ground upon which they are to be seen, and these differences (contrasts) are quantitatively effective for seeing not as differences but rather as ratios. The eye must also be adapted to a certain range of brightness represented by the general brightness of the object and its ground. It is to be noted here that the retina is capable of local adaptation, shown by the fact of after-images,

(a) *Cleveland Medical Journal*, March, 1916.

as well as of the state of general adaptation mentioned above, and that as a consequence extreme contrasts in the field of vision will, as the eye wanders over the field, continually cause states of maladaptation locally in various parts of the retina, in addition to the unfavourable circumstance of a high grade of simultaneous contrast.

It is not very far, then, from the established facts of physiological optics to the conclusion that unfavourable lighting conditions are those which present extreme contrasts. In general, experience in the matter of light installation has pointed very definitely to this view.

How is the relative merit of any light-distribution to be appraised? The most obvious criterion is the size of the smallest detail correctly recognisable under the conditions to be investigated, the determination of visual acuity; a refined procedure similar to the ophthalmologist's practice of "taking the vision" of a patient. A second criterion is the brightness-difference threshold—the least difference in brightness of two juxtaposed areas of the visual field that can be recognised. These two criteria have been investigated under certain fairly well specified distributions of light incident upon the eye.

The first set of data of any degree of completeness that we have is that of Depène, who used numerals as the test objects and investigated the limit of vision with various illuminations upon them; the eye being under the influence of a second light, independently controllable, of various intensities and at various angles with the line of vision.

His conclusions can be stated briefly: a reduction in visual acuity is found to take place when light from a source at an angle with the line of vision is allowed to fall into the eye, and this reduction is greater—

- (1) the smaller the illumination of the test object;
- (2) the smaller the angle of incidence of the second (glaring) light;
- (3) the greater the glare ("Blendung" is the word used, apparently meaning the intensity of the second light);
- (4) The greater the retinal area illuminated by the second light.

However, he notes by way of exception to these that with illumination upon the test object sufficient to give vision a value of 1.25 or more an increase is found in place of a decrease, when the conditions as enumerated are moderate in degree.

And further, from this data it is to be inferred that unless the illumination upon the eye is greater than that upon the test object and the angle made by the disturbing light less than 10° with the visual line, no diminution in the power of vision takes place. Such an extreme condition is not conceivable in illuminating practice except as an obvious abomination.

The speaker has made similar investigation, replacing the disturbing source of light by a uniformly bright background for the test object large enough to fill almost the entire visual field; the test object and surroundings being independently controllable as to brightness. Expressed in a similar way the results agreed with the above. Unless the surroundings were brighter than the test object the result was as good as that obtained in viewing the test object in dark surroundings. (a) And to

(a) If one imagine a uniform sky, with sun absent, the illumination from it upon a patch of snow on a plain would make the snow exactly as bright as the sky—supposing the snow to reflect diffusely all the light that fell upon it. Again, imagine such a white surface placed in the sky. Obviously it would have an exactly equal illumination upon it to appear as bright as the sky. If this be the test object, the sky, its surroundings and the snow patch on the ground, the observer's eye, we will see that the conditions described in

Depène's exception there was an approximate parallel, for surroundings of brightness equal to or less than that of the test object gave a slight increase over the result obtained with dark surroundings. This was not large, amounting on the average to not over 3 per cent.

The speaker has investigated a similar problem, where, instead of visual acuity, the discrimination of brightness-difference was used as a criterion. The least perceptible difference in brightness between the two halves of a small field is, according to Weber's law, a constant fraction of the brightness of the field. However, this fraction is found under certain circumstances to change with change in the brightness of the surroundings about as follows:—

With surroundings in excess of the field brightness the fraction increases promptly and progressively to a very high value, while in the opposite case, where the surroundings are relatively dark, there is also an increase, but this is very limited in extent. A definite and apparently limited optimal region was found at the point of equality.

The results of all this work may practically be summed up in a few words. On a field that is contrast-darkened visual discrimination is low. On a field seen in the midst of dark or relatively dark surroundings it is something short of optimal, while the optimum is to be found where field and surroundings are not far from equal in brightness.

We must remember that the above statement applies only to certain purely sensory criteria, and does not include the factor of ocular discomfort experienced at once or at length by the observer; nor does it apply to the question of eye-strain or the more general fag which may be the result of prolonged ocular effort under certain conditions. The typical lighting-conditions which have come under especial condemnation in these respects, as the result of the general experience of those who have given their attention to the practical problems of lighting, may profitably be compared with the experimental results described above to see how far the latter may be drawn into the explanation of the practical results.

One of these practical conditions is that of *local illumination*, where a light-source is placed rather close to the work of the individual and the general illumination of the room left to take care of itself. The result is that the general illumination is comparatively feeble, the work well illuminated, and the greater part of the worker's visual field relatively dark. We have seen that under corresponding experimental conditions the sensory capacity of the eye is somewhat augmented by a certain amount of light coming to the eye from the outlying parts of the visual field. The advantage, as measured by the sensory function of the eye, is not, however, comparable to the increased comfort and to the fact of the ultimate disappearance of complaints which result from an increase of the general illumination and the making of the local illumination auxiliary to this.

In contrast to this condition stand cases of general illumination in which excessively bright areas (in extreme cases naked lamp-filaments) appear in the worker's visual field. In such cases it is hardly possible, as we have already intimated, that the illumination upon the eye shall be in excess of that upon the work, as has been experimentally shown to be the condition of sensory depression. Yet when (as in some trades) the work consists of dark-coloured objects an equivalent condition may result. Otherwise the situation has been much alleviated by

the above remark (surroundings brighter than the test object) mean that the eye is receiving a greater illumination than the test object.

such expedients as frosted lamps or diffusing glass-ware—which have the result of spreading the direct light from the sources out over a larger area of the retina, which, according to one of the experimental conclusions which we have mentioned, would tend to reduce the sensory capacity of the eye rather than to increase it.

We see, then, that the conditions which are practically considered disadvantageous to vision do not correspond to those in which a large sensory depression has been found by experiment. This makes it appear that an experimental criterion of the merits of any arrangement of light should not primarily involve a threshold or other primarily sensory determination. Indeed, we may say with reason that the simple inability of the eye to appreciate a stimulus may only be a cause of discomfort or fatigue when that inability is taken as a signal for greater or repeated efforts of the eye to adjust itself to the work in hand. And these efforts must be closely related to the motor functions of the eye, to the movements of the pupils, of accommodation, or to the activity of the extrinsic muscles in determining accurate fixation.

Again, there is very little actual work, clerical or industrial, which is carried out at anything like threshold values of stimulus. The threshold may be defined as the physical value of the stimulus, expressed in suitable terms, at which from being ineffective it becomes effective. But since that value is found to be more or less indefinite and fluctuating, it is, in experimental work, often taken as the value of the stimulus at which it is effective in fifty per cent. of a large number of cases—or a point inferably equivalent to this. The range (for vision of detail) between the largest stimulus which is practically never effective and the smallest practically always effective—the region from 0+ to 100—per cent. effectiveness—is represented by perhaps 10 per cent. difference in the dimensions of the stimulus object. If, however, the stimulus is about double its threshold size, a 10 per cent. difference has little or nothing to do with its effectiveness, for at the lesser size it is already 100 per cent. effective.

It would seem reasonable, from this, to suppose that conditions which so depress the sensory capacity of the eye that the threshold is raised 10 per cent. would not in any corresponding degree be difficult on *that account*, when the work it has to do involves stimuli far above the threshold as in the practical case. (b)

It is quite possible that any condition which ultimately induces undue fatigue must initially, in some way, show increased labour thrown upon the mechanism of adjustment of the eyes. A sufficiently reduced sensory function, if the eye is whipped up to meet it, might be adequate to explain fatigue. When such a modification of the sensory function is not demonstrable for the conditions of the work with a test-object comparable to the work itself, it can neither be used to explain eye-strain nor as an indication that such conditions will prove conducive to the same under prolonged exertion. (c) Rather should one look for evidence

(b) The conditions in mind here are the most general ones referring especially to clerical work. Work on dark or black fabrics may, for example, approach threshold values. In a printing office, a "shadowless" system of illumination may bring the typesetter's work nearer the threshold point: while such a system might be ideal in a situation where shadows are a drawback, as in a drafting room. All generalisations are dangerous. The character of the work is of the highest importance in the illumination problem, and this discussion restricts itself to the one kind except where expressly stated.

(c) It is not contended here that sensory depression as shown by an increased threshold may not be the result of fatigue, but rather that the investigation of the motor functions of the eye furnishes at once a promising field in which to look for an explanation of it and a possibility of a method for the physiological appraisal of lighting conditions.

of some more direct interference with the motor processes of the eye—not explicable perhaps except as reflexes—but directly demonstrable in the examination of the motor processes of vision. Such disturbances should presumably be evident in the time-relations of these processes, and should appear at once under the conditions without waiting for the advent of fatigue.

PSYCHOANALYSIS.

By AGNES SAVILL, M.D., M.R.C.P.

Physician, London Skin Hospital; Physician to Electrical Department, Medico-Psychological Clinic.

PSYCHOANALYSIS is in bad repute. Those who say they practise it are regarded not over kindly by their fellow physicians. The publications originating from Vienna and translated from the German tongue have excited a degree of repulsion which is apparently an almost universal experience at the first introduction to that school's literature on psychoanalysis. So unanimous a repugnance has in all probability a healthy cause, and points to a deep-rooted confidence in the innate righteousness of human nature which seems assailed by this recent school of psychologists. The common sense of the common man rises against the conclusions of Freud, which strip humanity of dignity and beauty. Freudians protest that they are misrepresented, that they employ the term "sexuality," which they read into every human activity, in a wide sense misunderstood by the uninitiated. We have heard Freud's disciples argue that pleasure in riding and motoring is sexual in origin, and still more advanced disciples state that every dream, even in normal individuals, when analysed deeply enough can be reduced to betray a repressed sexual desire of a primitive type. After reading their recorded cases and attentively listening to their discussions we remain hopelessly unable to grasp their esoteric meaning, or to understand why any other adjective with a personal emotional content, such as *theological*, should not equally well express the all-pervading significance of their *sexual*. Is it wonder then that the uninitiated are content to remain uninitiated, and continue to regard psychoanalysis as a dangerous obsession?

Our attention has been drawn to the fact that there is another school of practitioners of this new psychology, a school which, owing to the paucity of its translated publications, is scarcely known in England except by a few scholars who read German. Its home is in Zürich; its most prominent member is Dr. C. G. Jung. The English-speaking public can now make acquaintance with two volumes from the pen of this remarkable thinker, and will arise refreshed and strengthened to learn that if, as it would appear, psychoanalysis has come to stay, they can fearlessly permit their nearest and dearest, when in need of mental assistance, to relate their dreams and deeds to a practitioner of the Zürich school. "Analytical Psychology," (a) which has just appeared in England, contains papers written by Jung during the last fourteen years, and reveals the gradual development of his philosophy, which, with growing knowledge of mankind, has turned more and more from the Freudian interpretation of the human spirit. We understand that his "Philosophy of the Unconscious" is appearing in America, and we are certain that those who have studied "Analytical Psychology" will hasten to master the other volume when it is available in this country. We consider the subject so important at the present day that we make no apology for a short survey of Jung's position.

In the preface to "Analytical Psychology" Jung summarises what he frequent refers to in the volume—the divergent conclusions of the rival schools. Freud discovered the *technique* of psychoanalysis, and by his system all emotional content is reduced to sexuality. His method is reductive, seeks origins, is causal, and traces to the past. The method of the

(a) "Analytical Psychology." By C. G. Jung, M.D. Authorised translation, edited by Dr. Constance Long. Pp. 392; four illustrations. London: Baillière, Tindall and Cox. 1916. Price 12s. 6d. net.

Zürich school is constructive, and regards the potential and the future. Jung considers the two systems are characteristic of the two broad types of the human mind, which he terms extravert-and introvert (p. 347). He quotes that eminently practical psychologist, William James, who, in "Pragmatism," describes human thinkers as divisible into the Tough and the Tender-Minded. The points of view of these types are mutually exclusive. The Tough-Minded prefer objective and material things; they are positivist and empiricist. The Tender-Minded are interested chiefly in things of the spirit and the inner life; they are idealist and monist. Jung regards the Freudian school as empiricist, according to the psychological life a place only as the effect of sensation; whereas the Zürich school considers the environment of a man as less important than the dominating principles of his inner life.

Jung has not an easy style, and many pages demand frequent reading ere their meaning is fully grasped. His earliest paper contains an illuminating study of a case of multiple personality, written, we believe, before the appearance of Frederick Myers' epoch-making volumes on "Human Personality." Jung traces how the personalities corresponded to the patient's conscious wishes or repressed ideas, thus bringing the phenomena into line with the dreams of the neurotic. The physician will find much food for thought in the chapters on the Association Method, Dreams, Psychoanalysis, and the Content of the Psychoses, presented as these are by a remarkably original and deeply reflective student of life. Jung denies that the psychoanalyst forces interpretations of dreams, and gives advice to the patient. "In direct contrast (p. 207) to all previous methods, psychoanalysis endeavours to overcome the disorders of the neurotic psyche through the subconscious, not through the conscious self." The true psychoanalyst never persuades or suggests, but follows the patient's own working-out of his problems. Dreams provide the readiest route to the subconscious, but free association gives the clue when the subject declares he never dreams. Dreams follow while the course of analysis proceeds. Freud holds that the dream is a symbolic veil for the repressed desires in conflict with the ideals of personality. Jung condemns this as an inadequate or incomplete explanation; the dream is rather the "subliminal picture of the psychological condition of the individual in his waking state"; it "discloses to us the secrets which our unconscious self enviously hides from our consciousness, and it does so with astonishing completeness." Jung has been led to the conclusion that "the religious and philosophical forces—the so-called metaphysical needs of the human being—must receive positive consideration at the hands of the analyst." This independent opinion sounds almost like an echo of William James' "Will to Believe." The common sense of the common man, a generation ago derided by science, is being vindicated by the leading thinkers of the present day. Jung continues (p. 234): "By means of psychoanalysis the connection between the conscious and the libido in the unconscious is re-established. Considered from this standpoint, psychoanalysis no longer appears to be a mere reduction of the individual and his primitive sexual wishes, but it becomes clear that it is a highly moral task of immense educational value." The interesting vistas of thought opened up by this book remind the reader of Bergson. Jung admits (p. 351): "I realise that my views are parallel with those of Bergson, and that in my book the concept of the Libido which I have given is a concept parallel to that of (Bergson's) *élan vital*. My constructive method corresponds to Bergson's 'intuitive' method . . . When I first read Bergson, a year and a half ago, I discovered to my great pleasure everything which I had worked out practically, but expressed by him in consummate language and a wonderfully clear philosophic style."

Throughout history it has been observed that great thinkers, working about the same time with widely differing data, frequently arrive, quite independently, at the same conclusions. The similarity of the conclusions reached by three men of such diverse experiences as James of America, Bergson of France, and Jung of Switzerland, speaking respectively the

English, the French, and the German language, is not a little astonishing, and of cheerful promise for the twentieth century. All maintain the power of the human soul, and testify to the validity of many of the uneducated beliefs which forty years ago appeared to conflict with the testimony of science. James describes the enormous reserve energy usually lying dormant in the subconscious, and drawn upon only in the great moments of life. He expresses his deliberate opinion in these words: "The further limits of our being plunge into an altogether other dimension of existence from the sensible and merely understandable world. We belong to it in a more intimate sense than we belong to the visible world . . . In communion with the Ideal, new force comes into the world . . . actually exerts an influence, raises our centre of personal energy and produces regenerative effects unattainable in other ways." And Bergson's oft-quoted paragraph will here bear repetition: "La vie entière, depuis l'impulsion qui la lança dans le monde, nous apparaît donc comme un flot qui monte, et que contraire le mouvement descendant de la matière. Sur la plus grande partie de sa surface, à des hauteurs diverses, le courant est converti par la matière en un tourbillant sur place. Sur un seul point il passe librement, entraînant avec lui l'obstacle, qui alourdira sa marche mais ne l'arrêtera pas. En ce point est l'humanité."

In the subconscious of every individual, Jung believes, dwells or manifests this libido, élan vital, or creative impulse. In the neurotic there is a subconscious conflict of impulses, and by bringing these to the conscious level of the personality harmony, and consequently increase of power, is restored to the mind. Energy wasted in the subconscious conflict is set free to be used by the conscious will. With this conception of conflict it is evident that many of the so-called sensitive natures must live on the verge of developing a neurosis, if indeed they are not already neurotic; but with this definition there can be no shame in acknowledging the existence of the condition. Then comes the opportunity for the wise psychoanalyst. "The neurotic is ill . . . because he has not yet found a new form for his finest aspirations" (p. 277).

It must not be supposed from the above that Jung is blind to the sexual origin of many neuroses. On the contrary, in many cases he has found that analysis confirmed Freud's observation, and for certain subjects he holds broad views on sexual morality. He emphasises the far-reaching effects of sexuality in the life of both men and women; its power to raise to heaven or drag to the depths; according to the manner in which it is manifested, to elevate and harmonise, or to degrade and dissociate the personality. The place Jung attributes to sexuality is, however, very different from that of the Viennese school. It is not unfair to represent the two views thus: "Matter," said the scientist of forty years ago, "is but crass matter; man develops from matter, and therefore he can cry be matter. All his qualities can be explained by physical laws; the lowest explains the highest." The modern scientist says: "If man comes from matter, then matter cannot be crass matter, because it holds such a potentiality. The end explains the beginning; seek the meaning of the lowest in its highest development." The Viennese school seeks the meaning of man in his primitive sexual roots; the Zürich school looks at the flowering branches of man's social activities and aspirations.

If some knowledge of philosophy is an asset in the equipment of the average physician, it is an essential study for the man who deals with the neurotic and the mentally disordered. Only a trained psychoanalyst can criticise the details of Jung's reasonings, but the common man's verdict proving usually on the side of truth, we unhesitatingly state our confidence in the ultimate decision of science in favour of the Zürich school. Many details will doubtless be altered with wider experience of human qualities and powers, but the main principles will probably stand the test of time. We confess still to hold some doubting scruples as to the future of this new science, so potent for evil and for good. Its members claim that they

do not influence the patient; they merely assist him to express what lies in his subconscious. We point to the different interpretations given by these two schools, and ask how is it possible that these are not employed by the operator, consciously or unconsciously, so as to stamp for life the character of an impressionable analysed individual. We feel that we should exert the utmost care in the present stage of development of this young science in the selection of the operator suitable to the patient whom we advise to undergo the analysis. No protest that influence is not consciously used will convince us that the choice of analyst is not more important than the choice of surgeon. The clumsy knife may maim or slay the body; injury to the soul is of infinitely greater moment.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

IS THERE NEED FOR ADDITIONAL MEDICAL TRAINING IN RELATION TO VENEREAL DISEASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I am disappointed. I had looked to you to protest against the libel of the Commission and of those who issued the circular about venereal diseases. In my student days—now unfortunately very long ago—the standing gibe was that all students knew at any rate everything about one disease—gonorrhœa in the male—or, as “Sinapis” puts it, assimilated the teaching with avidity on this subject. He now implies that those ideas were all wrong and the commission right, and that men qualified only ten years ago practically know nothing about the gravity of the disease. I protest against this assumption. Are the present teachers only recently qualified men? If not, they must be classed by “Sinapis” as antiquated. How did they get their knowledge? But perhaps he excepts teachers and specialists—a favoured class who have miraculously gained some special knowledge, even though they were qualified over ten years ago.

Bacteriology may have explained treatment, but I assert has not advanced it in gonorrhœa. The remote effects of gonorrhœa in the female are no more preventable now than they were half a century ago, although surgery may remove the effects. I have looked up the treatment of gonorrhœa in the male in old classics and in the present most-read text-books, and find practically no difference in the recommendations, except for the introduction of a few new drugs, such as hexamine, and the substitution of protargol for argent nit. Vaccines are of very doubtful efficacy. The internal treatment is as much in dispute now as it was in the time of Graves, Tanner, or Warburton Begbie. This proves research, not obsolescence. I do not, from consideration of your space, enter into the subject of syphilis, but I think there is not much new to be learned even about it as to treatment since the time of Donovan, Collis, and Hutchinson, but what is new, e.g., the Wassermann test, spirochaetes, 606, and grey oil have been assimilated. Depreciation of our profession, if justifiable, might, I think, be left to those outside the profession; but if not justifiable, should be resented by our journals. In this case, I contend the criticisms are unjustifiable.

I am, Sir, yours truly,

JAMES HAMILTON, M.D.

Chelsea, S.W.

May 12th, 1916.

THE WANT OF COHESION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Noticing in your current issue that you remonstrate against the lack of cohesion amongst the profession I would bring the following fact to your attention. As the possessor of a recent testimonial from the Serbian Government for work done in 1915, I applied to the Wounded Allies Committee, Sardinia House, for work. I was invited to fill up a form as to qualifications, etc., but towards the end it ran thus:—Does the applicant desire to be paid or unpaid?

When the Committee came to this portion of the form, and reading that I had expressed myself as desirous of some remuneration, their visages changed most pronouncedly.

Although the profession does much work for nothing I consider it to be better policy to take the remuneration in cases of this kind, and then return it either directly or indirectly as I have done with some of the money I received from the Serbian Government (which still owes me £10 by the bye). I informed the Committee that I objected to this undercutting, and there the matter ended.

I am, Sir, yours truly,

OVER AGE.

May 12th, 1916.

CONSCIENCE AND OTHER MATTERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Because I have asked that certain offenders (if so they must be regarded) shall receive the trial the Law ordains for them, Dr. Clave Shaw again attempts to fasten on me his charge of “sympathy” with them—and then talks of attorney-damning!

Most of the quotations he speaks of do not even refer to conscientious objectors, but to conscience. The issue is plain enough: I have asked for impartiality from the Law, which, as a saying has it, supposes the judge to be on the side of the accused; and I have contended that Conscience, in its usually accepted sense of the word, is a super-mental entity. I would have said “in its popular sense,” but that Dr. Shaw appears to regard this adjective as synonymous with “inaccurate.” Whether I have made good my case your readers, if sufficiently interested in my previous letters, must judge from them.

Dr. Shaw's answer to the plea for impartiality is simplicity itself: The Law has seen fit to change its mind. The same day which brought this answer brought also an example of the consequences of the change. I subjoin an extract from a press report of proceedings in the House of Commons on the 9th inst. The statements of Mr. Rowntree appear to have been unchallenged.

“At question time an important aspect of the compulsion question was raised. Mr. Rowntree, the Liberal member for York City, asked the Prime Minister whether he had yet received the answer to his inquiries into the case of Rendal Wyatt, a graduate of Cambridge University, who, along with other conscientious objectors to military service, was being punished by daily confinement for a period of time in a dark cell and in irons and fed upon a diet of bread and water in the military prison at Harwich Circular Redoubt. Was it true that whilst these inquiries were pending Wyatt, along with 16 other conscientious objectors, had been sent to France? Could the Prime Minister state what duties these untrained men who felt they could not undertake military service would be expected to undertake there?”

“Mr. Asquith replied: I am inquiring into this case, but I have not yet been able to ascertain whether Rendal Wyatt has been sent to France. If

he has he will presumably be engaged on the duties mentioned by the Under-Secretary for War in an answer given to the hon. member for Blackburn on April 19th.

"Mr. Rowntree strongly urged that such men should be removed to civilian prisons, and Mr. Snowden asked whether, in France, the death penalty would not be inflicted on them."

At this point a reflection occurs to one. The Law may "see fit to change its mind" concerning other obnoxious persons than conscientious objectors, and the Periphery of this and other weeks' issues throws a lurid light on the possibility of medical men being affected by this attractive versatility. At present the mind looks like changing on Insurance Act matters and on Notification Fees. Does Dr. Shaw applaud these changes as well? If so, our foes are indeed of our own household.

Yes, there is a false coinage of words as well as the genuine currency. And Dr. Shaw's use of the word "knowledge" in commenting on Mr. Arnold Bennett's prophecy lacks the ring of true metal. Whence came this "knowledge" to the conscience-stricken German, and how was it "put into" him? Not through his Kaiser, not through his officers and teachers, not through the (to him) evil consequences following his devilries. For these crimes happened also early in the war when he was sweeping onward to the gates of Paris. Even then there were instances of soldiers who were overcome with shame for the work they did. What was it which made them ashamed in spite of training, environment, and orders? What, as I have asked in my last letter, conditioned their soul's response to a new crisis in its moral life? Had these cases happened in this year, when Germans are beginning to suspect that "Frightfulness does not pay," something might be said for Dr. Shaw's view.

Doubtless many mental processes may be understood in terms of mathematics. But what if the experience of men for thousands of years, that conscience is a supermental entity, be true? Attention and memory may be after some fashion weighed and measured, but this strange force which tells a man in the hour of guilty victory that his triumph is a guilty one—what "graph" will estimate this? From the quiver of shafts, barbed and other, which your other correspondent, "A Student of Psychology," obligingly holds out, I select Lavater's; "Conscience is wiser than science."

Dr. Shaw thinks that an innate knowledge of right and wrong, which, of course, carries with it the power to choose between them, will sap our striving to do what is right. The men who have borne the strongest witness to such a power have not been marked by the cessation of such a striving. As he has mentioned the New Testament, I cite again the case of St. Paul; "and herein do I exercise myself, to have always a conscience void of offence toward God, and toward man." None will question the sense in which Paul used the word "conscience" in this avowal, and the striving is evident enough. (By the way, he seems to have got a hearing at least before his Tribunal, although law processes then as now were not attended with feverish activity.)

The case has been argued, and must now go to the jury. They will, I hope, accord me more consideration than I have received from Dr. Claye Shaw.

I am, Sir, yours truly,

L. GWILLIM DAVIES, M.D.

Histon, Cambridge.

May 13th.

P.S.—I find from the Press of the 11th inst. that the case of the Quaker schoolmaster, Mr. Wyatt, is much worse than shown by the cutting, and that many other cases, unchallenged in the House, have occurred of barbarities inflicted on such men as he. No Prussian barrack-square can have witnessed much worse. I enclose the cutting, but fear it is too long to insert. But let medical men study these things, I say, and consider what may befall those concerning whom the Law changes its mind: there are more ways of killing a dog than by hanging him.

CONSCIENTIOUS OBJECTORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your readers should be very grateful to that eminent psychologist, Dr. Claye Shaw, for exposing the sophistries of Dr. L. Gwillim Davies. Error lurks in generalities. The word conscience is a catch-word—a mere phrase used as an argument for or against anything; an attempt on the part of the disputant to impose his own individual sentiment on other people, without giving them a reason for it. Bentham in his *Introduction to the principles of morals*, says: "It is curious enough to observe the variety of inventions men have hit upon, and the variety of phrases they have brought forward, in order to conceal from the world, and, if possible, from themselves, this very general and therefore very pardonable self-sufficiency. One man says he has a thing made on purpose to tell him what is right and what is wrong; and that is called a 'moral sense': and then he goes to work at his ease, and says, such a thing is right, and such a thing is wrong. Why? 'Because my moral sense tells me it is.'"

Being a doctor, and therefore a learned man (*doctus*=learned), Dr. Davies ought to know that the mind at birth is a *tabula rasa* (the white page of John Locke), and accordingly that there is no such thing as innate ideas, only innate capacities. Hence, we do not bring with us into the world any idea of right and wrong; it is only experience which endows us with such concepts. Some people interpret these terms according to their own convenience. For example, certain financiers consider people who part with their money readily as mugs. The lion's "good" is what is good for him; it is the antelope's notion of "wrong." Has Dr. Davies ever read Hartley, Locke, or Mill? or even Hume or Helvetius?

I am, Sir, yours truly,

W. WINDYBANK CARTER

(Father of three soldier sons).

Watford, Herts.

MR. STEPHEN ELGAR, of Ramsgate, left £1,000 to the Ramsgate General Hospital.

THE Skinners' Company have made a grant of £21 to Queen Charlotte's Lying-in Hospital, Marylebone Road.

EXCLUDING Admiralty surgeons and agents, 1,118 qualified medical men are now employed in connection with the Navy.

MRS. FANNY SAYCE, of New Barnet, Herts, left £300 to the Victoria Cottage Hospital, Barnet, and £200 to Guy's Hospital.

SIR ANDREW RICHARD SCOBLE, of Wimbledon, left £5,000 each to King Edward's Hospital Fund and the Convalescent Home, Orphanage, and other charitable works carried on by the Sisterhood of St. John the Baptist at Clewer.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ANNUAL MEETING HELD THURSDAY, MAY 4TH, 1916.

DR. M. HANDFIELD-JONES in the Chair.

The officers and council for 1916-1917 were elected.

L. Carnac Rivett, F.R.C.S., was elected a member of the Section.

The PRESIDENT made a few sympathetic remarks on the loss that the Section had sustained by the death of Dr. R. Drummond Maxwell.

Dr. HERBERT SPENCER read a short communication on a fourth case of

PRIMARY CANCER OF THE FALLOPIAN TUBE

(his three earlier cases had been published in the *Journal of Obstetrics and Gynæcology of the British Empire*, 1910).

The tumour was removed, together with the uterus (which contained an adeno-myoma and a small myoma) and a simple ovarian cyst with which the ostium of the tube communicated (tubo-ovarian cyst). The cancer occurred in the ampulla of the tube, to which it was confined. The growth was a carcinoma resembling in many places a sarcoma. Extensive keratinisation was present. Sections were shown demonstrating the origin of the cancer from the epithelium of the tubal plicæ. The growth recurred in the pelvic colon, a piece of which was excised and an end-to-end anastomosis made. The growth again recurred and was not influenced by X-ray treatment.

The sequel of events in developing cancer in this case appeared to be (1) salpingitis with simple invasion of the muscular wall by tubal glands; (2) papilloma; (3) malignant invasion of the wall by glands, the epithelium of the glands and of the papilloma becoming proliferated to form cancer.

Dr. H. RUSSELL ANDREWS showed a specimen of "bilateral carcinoma of Fallopiian tube." The patient was aged 55, married twice, childless. The menopause occurred at 49. In December, 1914, she began to have a discharge of blood, and later the discharge "turned to pure water." She said that she had lost as much as a quart a day. She was admitted to the London Hospital in March, 1916. The profuse watery discharge was thought to suggest the presence of carcinoma of a Fallopiian tube. The abdomen was opened, and both tubes were found to be greatly dilated, the left forming a mass 6 inches by 2½, the right 4 inches by 2. The uterus was atrophic, and showed nothing abnormal. The cavity of the right tube was almost filled by papillary growth; the left contained a good deal of similar growth, but was not so tightly filled.

Dr. Andrews considered that the growth was a papillary carcinoma, but thought that there might be some discussion as to whether it should not be called a papilloma, and suggested that the specimen should be referred to the Pathological Committee.

Lady BARRETT showed a specimen of "primary squamous-celled carcinoma" arising in a tuberculous Fallopiian tube. The patient, æt. 46, married nine years, sterile, had complained of pain in the right iliac fossa for ten years. There was a hard well-defined tumour in the right side of the lower abdomen. On vaginal examination, Douglas' pouch and both lateral fornices were filled up by the swelling. The uterus and both tubes and ovaries were removed. The right tube showed very extensive tuberculous disease. The left tube

was lined by tuberculous granulation tissue, and towards the outer end there was squamous-celled carcinoma with keratinisation and a few cell nests. There was no carcinoma in the uterus, and numerous sections of the ovaries failed to show the presence of "dermoid" tissue.

Dr. CUTHBERT LOCKYER showed a specimen "Precancerous changes seen in the displaced epithelium of nodular salpingitis."

Some remarks sent by Mr. Alban Doran were read by the SENIOR SECRETARY:—

Mr. Alban Doran, who has read the records of later cases of cancer of the Fallopiian tube with much interest, has come to the conclusion that primary cancer is the rule—a statement he would not have dared to make in 1888, when he described the first case under his personal observation. The malignancy of tubal cancer is of a very high degree, even after the most modern and radical operations, yet after-histories rarely include any suggestion of a primary seat other than the tube. How comes it, if according to some authorities tubal cancer is always secondary, that the primary disease happens to be always latent when a tube is amputated for carcinoma? Do we often meet with such a pathological phenomenon in the case of the breast or tongue? The Wells-Bickersteth case of papilloma teaches us that a new growth of a type which later experience has shown to be very liable to malignant degeneration may be absolutely confined to the Fallopiian tube; when such degeneration occurs the tube must of necessity be the primary seat of carcinoma.

Dr. HEYWOOD SMITH discussed Dr. Spencer's communication, saying that he should like to ask Dr. Spencer with regard to the first case he narrated, whether, if the oviducts had been opened at once and had been found malignant, and if, therefore, the other one had been removed, in his opinion it would have given the woman a better chance, or was it another case where a woman had neglected to realise the importance of abdominal symptoms.

Dr. F. J. McCANN discussed Dr. Andrews' specimen.

Drs. SPENCER and ANDREWS replied.

Dr. HENRY BRIGGS read a paper on

UNILATERAL SOLID PRIMARY ADENOMA OF THE OVARY.

The recognition of a benign solid glandular growth—an adenoma—as a rare primary tumour of the ovary was the main purpose of this short communication.

Allusion was made to the fact that the numerical preponderance of fibroma over sarcoma had been long and well established, whilst amongst solid primary glandular growths any corresponding statement concerning adenoma and carcinoma was still wanting; for this omission rarity and uncertainty were responsible.

In support of the paper, three cases of unilateral large solid adenoma of the ovary were described.

Case I.—S. S., æt. 54, 8 by 4 by 4½ in., adhesions, ascites, 1 gall.

Case II.—A. L., æt. 38, 7 by 5 by 5½ in., adhesions, no ascites.

Case III.—Mrs. McG., æt. 62, 3½ by 3½ by 3½ in., no adhesions, no ascites.

An almost borderland case of unilateral solid cancer of the ovary was included.

Case IV.—A. G., æt. 36, 10 by 7 by 6½ in., universal adhesions, no ascites. Estimated freedom from recurrence, 10 to 12½ years—death from cancer 15 years after ovariectomy.

The inclusion of this case (i) supplements the report on February 4th, 1915, by Dr. Herbert Spencer, before the Obstetrical and Gynæcological

Section, on a ruptured unilateral solid cancer, 6 by 3½ inches, of the ovary, ovariectomy, subsequent pregnancies and good health after seven years; and (2) associates with it an even longer after-history of freedom from recurrence.

In this case an apparent surgical triumph over a large, adherent, cancerous tumour is singular enough to suggest, if not to establish, the tumour's innocence and an entirely new and independent cancerous growth during the last four of the fifteen years of the patient's life subsequent to the ovariectomy.

To his colleagues in pathology, Professors Ernest Glynn and Beattie, the reader of the paper expressed his indebtedness for a scrutiny of the histological details; in two, Cases I. and II., the alveoli were lined by short columnar or cubical cells in a single layer; in one, Case III., an intermediate arrangement, *i.e.*, the alveoli were not packed, they were lined, not with one but several layers of short cylindrical cells, curtailing and usually not obliterating the lumen of each alveolus, and in one of the growths, Case IV., the alveoli were fully packed with similar epithelial cells.

Dr. HERBERT SPENCER discussed the paper. He thought there was need for further careful study of solid ovarian growths with glandular contents. His own case, alluded to by Dr. Briggs, was certainly not an adenoma; it was a soft growth, and microscopically was a medullary carcinoma, exactly resembling one of Dr. Briggs' cases which recurred. Although over 12 years elapsed before recurrence occurred in Dr. Briggs' case, that did not prove that it was not a true recurrence, which had been known to occur after more than twenty years in cancer of the uterus. In the light of Dr. Briggs' case, his own patient, who had since had children and remained well for some years, would be watched with some anxiety. The most interesting cases of solid "adenoma" were those hard tumours containing masses of epithelial cells diffused throughout the fibrous stroma, of which he had removed one example, and several specimens had been exhibited before the Section. These hard, slow-growing tumours, he had no doubt, were simple fibro-adenomata, although the opinion that they were carcinomatous had been given by several members of the Section when Dr. Giles' specimen was exhibited.

In reply, Dr. BRIGGS said that of the clinical histological puzzles none could be more difficult than adenoma *v.* carcinoma.

Mr. J. D. MALCOLM related a second case of "pneumoperitoneum" probably induced by the bacillus aerogenes capsulatus. Both Fallopian tubes, the left ovary and the vermiform appendix were removed from a woman, *æt.* 38, on account of inflammatory disease. Three days later the abdomen began to distend, and continued to do so until it was blown up like a tense balloon. On re-opening the peritoneal cavity several days after the first operation a large quantity of odourless gas was set free and the distension immediately disappeared. The patient made a good recovery. The case recorded in the Surgical Section (*Pro. Royal. Soc. Med.*, Vol. III., Surgical Section, pp. 13-24), in which a similar condition followed removal of the cancerous rectum, was referred to, that patient being about and well six years after this operation. In both cases, arguing by a process of exclusion, it was concluded that a micro-organism, probably the bacillus aerogenes capsulatus, was the cause of the development of gas. The innocuous character of this bacillus under certain circumstances was pointed out. The pneumo-peritoneum in these two cases was not diagnosed until the peritoneal cavity

was reopened with a view to the relief of a supposed intestinal obstruction by draining the intestine after the fashion described in the 8th Vol. of the Society's Proceedings (*Pro. Royal. Soc. Med.*, Vol. VIII., Obst. and Gyn. Section, pp. 16-24). It was suggested that possibly some cases of pneumo-peritoneum had been overlooked by refraining from operative treatment for distension of the abdomen by gas.

Drs. F. J. McCANN, CUTHBERT LOCKYER, C. HUBERT ROBERTS and H. RUSSELL ANDREWS discussed the paper, and Mr. MALCOLM replied.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE ANNUAL CONGRESS.

THE Annual Congress of this Society was held on May the 4th, 5th and 6th, under the presidency of Mr. WALTER H. JESSOP, F.R.C.S.

The discussions took place at the headquarters of the Royal Society of Medicine, and the clinical meeting at the Central London Ophthalmic Hospital.

PRESIDENTIAL ADDRESS.

THE PRESIDENT, in the course of his opening address, referred with pride to the fact that the Society was now presenting its thirty-sixth consecutive annual volume of transactions. The Bowman Library was the finest and most complete ophthalmological library in the world, and he pleaded for the co-operation of members in keeping it well supplied with literature of interest to the speciality. He also asked members to notify any changes which had occurred in cases discussed, so that their sequelæ might be known. The Society was this year the poorer by the death of two brilliant workers: Mr. George Coats, of London, and Professor Straub, of Amsterdam. A special tribute was due to the first-named of these for his great help to the Society, especially in its troublous time three years ago. Mr. Jessop devoted the main part of his address to the subject of some ophthalmic lessons of the war. Thanks to the efforts of Colonel Lister and others, the treatment of cases of eye injury in the war had been good. He, the speaker, had, as yet, found no case of sympathetic ophthalmitis, which happy fact was attributable to the precaution of removing every portion of a smashed or broken eye. In the war of 1870, sympathetic eye trouble was reported in 55.6 per cent. of the cases of severe injury to that organ or the orbit. The war had taught ophthalmic surgeons much on the subject of papilloedema, a question which had been patiently worked at by Mr. Leslie Paton and Dr. Gordon Holmes. He proceeded to refer to trench nephritis and the eye changes seen in association with that disease. He regarded it as a toxic condition, and referred to the occurrence of oedema of the retina, ocular hæmorrhages, and the formation of white plaques. In the worst instances the blood pressure was high, but it varied much in different cases. In uttering a word of encouragement to younger ophthalmologists in the accurate observation of cases, he laid stress on the examination being conducted in daylight wherever possible.

On the motion of Sir ANDERSON CRITCHETT, the president was cordially thanked for his address.

Mr. J. HERBERT FISHER read a paper on "LEBER'S DISEASE (HEREDITARY OPTIC ATROPHY): A SUGGESTION AS TO ITS CAUSE."

He suggested that the causal agent might be a disturbance of the pituitary body, of temporary

duration, and moderate in degree, implicating the visual pathway. If his view proved to be correct, he thought organo-therapy might be expected to do good. During pregnancy the pituitary gland might be enlarged to two or three times the normal, and a milky secretion could often be squeezed out of it. There was known to be a close relationship between the pituitary and the sexual glands. Moreover, the pituitary and the optic chiasma were in such close contiguity that any small swelling of the former would extend to and make itself felt in the latter. He exhibited a skiagram showing a honey-comb-like shadow in the situation of the pituitary.

The paper was discussed by Sir GEORGE BERRY, Dr. G. MACKAY, Dr. S. A. KINNEAR WILSON, Mr. STACK, Mr. STEPHEN MAYOU, and Dr. C. O. HAWTHORNE.

Mr. FOSTER MOORE contributed a paper on "THE RETINAL CIRCULATION IN ARTERIO-SCLEROSIS."

He agreed with Priestley Smith that a high pressure in accessible arteries in elderly men did not necessarily mean high pressure in the ciliary capillaries. A sudden obstruction of circulation due to thrombosis in an artery might lead to relative starvation of tissues, and the patient might awake to find himself blind. Sometimes there was an equally rapid recovery of vision. It was not necessary to invoke spasm of the retinal artery as a cause.

In the discussion which ensued, the PRESIDENT, Mr. BICKERTON (Liverpool), Mr. BLAIR, Lieut.-Col. ELLIOT, Dr. C. O. HAWTHORNE and Mr. ELMORE BREWERTON took part: and Mr. FOSTER MOORE replied.

Dr. S. A. KINNEAR WILSON read a paper on "DYSMETROPSIA,"

meaning thereby a defect in the capacity to appreciate the size and distance of objects. The cases of this peculiar condition he divided into (a) those in which the lesion was presumably peripheral, (b) those in which it was probably central, (c) psychical cases. In a case of the latter the young woman, who was the subject of hysteria, always saw the right half of objects much larger than the left; and if two shillings were placed side by side, she considered that the one on the right-hand side was a half-crown. In a case of occipitoparietal tumour, the objects seemed so near that they appeared to be practically touching the observer's face. Dr. Wilson considered that in judging of distances and sizes of objects we learn more from the retina than from so-called kinaesthetic impressions.

The paper was spoken to by Sir GEORGE BERRY, Dr. CRAIG, Mr. CYRIL WALKER, Dr. G. MACKAY, and Mr. GREY CLEGG: Dr. WILSON replied.

Mr. M. HINE recorded some observations with the Schiötz tomometer, as a result of which he was of opinion that eserine produced no injury, although many of the cases observed were in children: and that it definitely reduced intraocular tension, a view shared by a number of workers who had recorded their observations.

Mr. E. TREACHER COLLINS read a paper on "CONTUSION HYPOTONY."

He pointed out that diminution of tension after contusion of the eye, apart from any perforation of the globe, was not infrequent. In most cases normal tension was restored in a few days: in others not for several weeks, and in some it remained so long as to be likely to be permanent. The causes he discussed under the following heads:—

(1) Diminished secretion: divisible into (a) from nerve inhibition, (b) from vascular disturbance, (c) from epithelial damage.

(2) Increased excretion, namely (a) through normal channels, (b) through newly-formed channels. After quoting several illustrative cases he submitted the following conclusions: (1) Hypotony following contusion of the eyeball may be due to different causes, more than one of which may be present at the same time. (2) When of short duration it is probably due to an increased rate of excretion of the intraocular fluid through the expanded normal channels of exit: or, possibly, to some arrest of secretion from paresis of the vasoconstrictor nerves. (3) When of long duration it may be due to (a) the formation of new channels of exit for the intraocular fluid from the anterior chamber from either an internal scleral rupture, or rupture of the pectinate ligament, (b) the cutting off of blood supply to the ciliary body from rupture of the anterior ciliary arteries, or (c) possibly the detachment of the pars ciliaris retinae.

(4) If accompanied by extensive hæmorrhage into the anterior chamber, either the canal of Schlemm has been opened up by an internal scleral puncture, or the anterior ciliary arteries have been torn across from cyclodialysis.

(5) If, when the blood has been cleared away, a portion of the iris has disappeared from view, as though an iridectomy had been done, then there has been cyclodialysis with rupture of the anterior ciliary arteries.

(6) If, in the course of time, a translucent area appears just outside the sclero-corneal margin, like that seen in cystoid cicatrix, then there has been an incomplete internal rupture.

(7) If the anterior chamber, without extensive hæmorrhage into it, becomes markedly deepened in the whole or part of its circumference, there has probably been a rupture of the ligamentum pectinatum, limited to the pillars of the iris, and of the ciliary muscle, prolonging the angle of the anterior chamber outwards.

(8) If the lens is dislocated laterally and the retina detached, the vitreous humour has probably come forwards into the circumlental space, and may have dragged the pars ciliaris retinae away from the pigment epithelium.

Lieut.-Col. ELLIOT and Mr. CRIDLAND discussed the two papers, and the authors replied.

A discussion on

"FOREIGN BODIES IN THE EYE AND ORBIT"

was introduced by Mr. A. L. WHITEHEAD (Leeds) and Mr. J. HERBERT PARSONS (London). Mr. Whitehead referred to the frequency with which the eyeball was penetrated by foreign substances in industrial centres. Sometimes the particle passed completely through the globe, and the war had demonstrated the extraordinary penetrating power of metals when propelled by high explosives. He enumerated the various forms of eye injury, and said that the prognosis and treatment of an eye containing a foreign body must depend upon a variety of factors, such as the introduction of septic organisms with the foreign body, the size of the substance, the site and depth of penetration, the nature of the substance. Copper, unless embedded in the lens, always set up localised supuration, with necrosis of tissue, and, if in the vitreous, phthisis bulbi. He discussed X-ray localisation, and the extraction of steel and iron by the electro-magnet. If steel were in the vitreous, he made a conjunctival flap, punctured the sclerotic behind the ciliary region, and inserted the point of the giant magnet, keeping the current on during withdrawal. In his hospital, the onset of sympathetic irido-cyclitis secondary to retention of a foreign body in the exciting eye was not common. An injured eye without useful vision

should be enucleated if there was even a suspicion of the presence in it of a foreign body. If a foreign substance were not giving pain or discomfort, it should be left alone.

Mr. HERBERT PARSONS discussed the

ANATOMICAL RELATIONS OF THE EYEBALL TO THE ORBIT,

and urged a more accurate study of the relations of the living eye to the bones, which could be done by the insertion of slips of lead foil in the cocainised conjunctival sac. The eye was least protected against missiles coming from a direction downwards and outwards. Despite the heat generated in a high-velocity missile, the particles entering the eye were not always sterile. The diagnosis, pathological condition, treatment and prognosis all depended profoundly on the nature of the foreign body. When the body could not be seen in the eye, skiagraphy must be employed, but this had its severe limitations. He regarded accurate localisation as most important. If this were not within 1 m.m. it might mean the needless sacrifice of an eye. Only rarely did a copper particle become encapsulated with restoration of useful vision. He discussed at some length the production of siderosis bulbi. Glass and porcelain might cause remarkably little reaction in the eye, but eventually the eye usually became disorganised following irido-cyclitis. The lens substance and the vitreous formed excellent culture media. The ultimate results of extraction of intraocular foreign bodies by the electro-magnet were of profound importance, and had not yet received their due attention. He concluded by alluding to the different operative measures according to the class of case, and the prognosis in them.

The debate was carried on by the PRESIDENT, Mr. HILL GRIFFITH, Dr. CRAIG, Mr. TREACHER COLLINS, Mr. GRAY CLEGG, Dr. FINZI, Capt. A. W. ORMOND, Mr. ARNOLD LAWSON, Mr. MAYOU, Mr. HAMILTON, Mr. CRIDLAND, Dr. HERN, Mr. ROWAN, and Mr. G. MACKAY. The authors replied.

A debate on the

TREATMENT OF THE SYPHILITIC EYE AFFECTIONS BY THE NEWER METHODS

was introduced by Mr. J. B. LAWFORD and Capt. H. S. BROWNING.

Mr. LAWFORD assumed that the "newer methods" dated from the introduction of organic arsenic compounds in the treatment of syphilis. In sleeping sickness, organic arsenic compounds, especially atoxyl, were already in use, and in spite of the occurrence of numerous cases of blindness following their administration in trypanosomiasis, the same preparations were extensively prescribed to patients suffering from ocular syphilis, as well as to those with other manifestations of the disease. The frequency of optic nerve atrophy after the use of atoxyl and kindred preparations of arsenic, soon led to the abandonment of those drugs. The introduction of salvarsan, in 1910, provided a more suitable and less dangerous arsenic compound, and this and neo-salvarsan have been employed very extensively in ocular syphilis. He suggested that as there was very general agreement as to the value and efficiency of salvarsan therapy in ocular lesions in the early periods of syphilis, primary, secondary and early tertiary stages (i.e., chancre of eyelids, iritis, cyclitis, etc.) discussion on this aspect from the clinical side would not be very helpful. In reference to the results with salvarsan in some of the later ocular manifestations of syphilis, concerning which much difference of opinion exists, he hoped for a profitable debate. He drew attention to the

use of salvarsan in oculo-motor paralysis, ophthalmoplegia interna, and optic nerve atrophy of late syphilis, and in keratitis of the congenital form: and quoted cases from his own experience and from published records. He concluded with a brief reference to the reputed noxious effects of salvarsan and neo-salvarsan upon the optic and other ocular nerves, and pointed out that, in the opinion of most observers, the complications met with after the administration of these drugs were, in reality, fresh manifestations of the syphilitic virus. Such development often underwent amelioration by continued use of the drug, differing absolutely in this respect from the nerve lesions following treatment by atoxyl. He submitted that there was no evidence that syphilis could be eradicated by salvarsan treatment alone, and that prolonged medication by the classical anti-syphilitic remedies was essential, even when the results of salvarsan treatment had been most brilliant.

Capt. BROWNING first dealt with the question of the diagnosis of syphilis, which too frequently rested on clinical evidence alone. All the further aids to diagnosis should be employed. It was not true that all cases of choroiditis were syphilitic in origin. In every case of suspected eye syphilis, a careful and systematic examination of the patient's whole body should be carried out, and repeated examination of the lesions should be made with the dark-ground condenser. Properly carried out, the Wassermann was one of the most reliable serological tests, and he considered the original method the most reliable for general use. But a negative Wassermann did not mean that the patient had not got syphilis. Laboratory tests should be considered in conjunction with all other known facts. Repeated doses of arsenical preparations, combined with mercurial treatment, were needed to bring about a cure. He proceeded to speak of the appropriate doses of various drugs, and methods of administration. Kharsivan he found more toxic than salvarsan, and neo-kharsivan even more so, and undesirable symptoms were more frequent after its administration than after salvarsan and neo-salvarsan. Every case must be treated on its own merits. His trials of Intramine and Ferrivine did not encourage him to continue their use.

The ensuing debate became general.

The Committee of the Society which had been appointed to investigate cases of detachment of the retina presented their report, through Mr. Leslie Paton. It detailed the findings in 85 cases, half of which were British. The best visual results ensued in cases in which reposition of the retina occurred after four or five months, though one case gave a good result after 18 months. In most of the cases some form of scleral puncture was carried out. None of the albuminuric cases were operated upon. Much satisfaction was expressed with the labours of the Committee, who were, on the proposition of Sir George Berry, cordially thanked.

Friday afternoon was devoted to the examination and discussion of an extensive series of cases of peculiar interest at the Central London Ophthalmic Hospital, Judd Street.

On Saturday the Society resumed the hearing and discussing of short papers. Major Cunningham and Professor De Lapersonne contributed papers on war injuries of the eye, in which they gave details of many cases, and discussed the best measures of treatment. Colonel Lister said that in the case of foreign bodies in the eye, so long as there was no prolapse of uvea or lens capsule, there seemed no danger in keeping that eye. The

lens had been frequently injured in the war. It was extraordinarily satisfactory that there seemed to have been no case of sympathetic ophthalmia: there could scarcely have been none, but he had not heard of any cases. He suggested a new operation for cases of prolapse of uvea, and emphasised the importance of avoiding tension, if necessary by making a counter-puncture. If an eye with a foreign body in it did not quiet down, the practice was to remove the eye. If it did quiet down, the eye was left to be watched and treated as required in England. He invited ophthalmologists to criticise the practice of those at the front, and allow the latter to have the benefit of such suggestions.

The following papers were read:

Dr. C. O. Hawthorne: Retinal changes in Glycosuria.

Capt A. W. Ormond: Treatment of Large Traumatic Hæmorrhages in the Vitreous.

Mr. J. Gray Clegg: Spontaneous Intraocular Hæmorrhages.

Capt. Beatson Hird: Notes on a Case of Tumour of the Retina (this was referred to a Pathological Committee).

HARVEIAN SOCIETY OF LONDON.

CLINICAL MEETING HELD ON THURSDAY, MAY 11TH, 1916.

The President, DR. EDMUND CAUTLEY, in the Chair.

The following cases were shown:—

(1) Dr. GRAHAM LITTLE: (a) Septic papillomatosis of the lower extremity which had led to great overgrowth of the limbs. (b) An ulcer of thirteen years' duration which had originated in a soft sore and led to extraordinary scarring.

(2) Dr. LANGMEAD: Intrathoracic tumour in a young woman. The X-rays revealed a shadow behind the upper part of the sternum, and the microscopical examination of an excised portion supported the view that the mass was lymphadenomatous.

(3) Dr. STEWART: (a) Multiple osteomata developing in an adult man. (b) A man who had been successfully operated on for temporo-sphenoidal abscess which reached to a depth of five inches from the surface.

(4) Mr. C. A. PANNETT. A patient with stone in the ureter. The accompanying radiogram demonstrated the stone in a dilated part of the ureter with an opaque bougie alongside of it.

(5) Dr. JAFFE: A woman with enlarged liver and jaundice.

Mr. COPE showed a photograph of the injuries caused by an electrical current of 11,000 volts on a patient who survived three days after the accident.

The cases were discussed by the PRESIDENT, Dr. LANGMEAD, Mr. PANNETT, Dr. DAVSON, and others.

SPECIAL REPORTS.

MEDICAL SERVICES IN MESOPOTAMIA.

GENERAL SIR JOHN NIXON, K.C.B., in a despatch dealing with the operations in Mesopotamia from October to December, 1915, refers to the medical services as follows:—

Major W. C. Croly, R.A.M.C., has been in medical charge of the staff at general headquarters, and has shown himself always the right man in the right place, and to have taken the keenest

interest in his work and care of those whom he had in charge. The medical services have had to face very trying and unusual conditions. On more than one occasion the number and severity of the casualties have thrown the greatest strain on them, but the organisation and efficiency of the arrangements have ensured as speedy an evacuation of the wounded as the means placed at their disposal permitted. In this connection I wish to bring forward the name of Surgeon-General H. G. Hathaway. The British General Hospital has throughout been in charge of Lieut.-Colonel D. J. Collins, Royal Army Medical Corps, whose zeal, energy, and organising power have rendered it a model hospital of its kind. Credit is also due to Lieut.-Colonel G. B. Irvine, Indian Medical Service, for his devoted and careful supervision of the Indian General Hospital.

Captain W. H. Hamilton, I.M.S., is also mentioned for having rendered good service.

OBITUARY.

DR. CHARLES WILKINSON, L.R.C.P. AND S., OF SCARBOROUGH.

THE death has occurred, in a nursing home, of Dr. C. A. Wilkinson, of Scarborough. Educated at Edinburgh, he qualified L.R.C.P. and S. in 1894. Dr. Wilkinson, who was 47 years of age, had only been ill four days. He had an extensive practice in Scarborough, where he had resided for about 18 years. He was formerly Deputy Medical Officer of Health for the borough, and was one of the Medical Officers under the Scarborough Board of Guardians. He was the founder of the Scarborough Branch of the St. John Ambulance Brigade, a work in which he took a great interest. He is survived by his widow.

DR. C. J. GIBB, M.D., NEWCASTLE-ON-TYNE.

DR. CHARLES JOHN GIBB, the oldest medical practitioner in Newcastle-on-Tyne, died in that city on May 13th in his 90th year. Dr. Gibb was the son of Dr. John Gibb, who practised in Newcastle for forty years. He studied in London and abroad, and qualified M.R.C.S., L.S.A. in 1847. In 1859 he took the degree of M.D., Durham. He was house surgeon at the Royal Infirmary in Newcastle for some years, and he was also lecturer in the Newcastle College of Medicine on anatomical demonstrations. Afterwards he became lecturer in pathology. During the cholera epidemic in Newcastle in 1853, when more than 1,500 deaths were recorded, Dr. Gibb assisted strenuously in stamping out the disease, and was the author of a report on "Epidemic Cholera."

DR. ARNOLD W. WARRINGTON LEE, M.D., F.R.C.S., MANCHESTER.

THE death is announced of Dr. Arnold W. W. Lee, which took place at Birkdale after a long illness. Dr. Lee was a comparatively young man. Educated at Owen's College, he qualified M.R.C.S., L.R.C.P. in 1889. Graduating M.B., London, in 1890, and M.D. in 1892, he also took the F.R.C.S., England, in the latter year. Specialising in obstetrics and gynaecology, he was surgeon to the St. Mary's Hospital, Manchester, and lecturer on Midwifery and Diseases of Women at Manchester University. He wrote largely on the subjects to which he devoted his professional life.

DR. J. G. HOPE, L.R.C.P. AND S., EDINBURGH.

THE death is announced of Dr. J. Gilbert Hope, 6, Royal Circus, Edinburgh. Dr. Hope, who passed away on Saturday evening after a short illness, was 42 years of age. He was a native of Edinburgh and qualified eighteen years ago. He had been in practice for twelve years in the North Side of the city, and was Medical Officer to the New Town Dispensary. Dr. Hope leaves a widow and three boys and a girl.

REVIEWS OF BOOKS.

ANATOMY (a).

THE essential portion of this volume extends to some sixteen hundred and fifty pages, many of which are in very small print, so that as regards size it competes with the majority of the text-books on systematic anatomy used, chiefly for reference, by students in this country. It differs from them, however, in the fact that only the bones, central nervous system, eye, ear and embryology are dealt with systematically. The rest of the book is concerned with the anatomy of the body considered in regions, and at the end of each of these sections there is a guide to the dissection of that "part." It is, in other words, a dissector's guide with the addition of a good account of osteology and an indifferent one of development. The present volume is too unwieldy for this purpose, and would be more popular if issued in two parts, and advantage might be taken of this alteration to use thicker paper and less trying print.

The book is a very good one, the least satisfactory section being that devoted to embryology, which contains a total of twenty-one figures, all of which deal exclusively with the very earliest phases. The formation and fate of such difficult and important structures as the septum transversum, pericardial cavity, pleural cavities and pleuro-peritoneal openings being without a single illustration.

In the table of sexual differences in the os innominatum, no reference is made to two of the most useful points, namely, the shape of the sciatic notch and the sulcus pre-auricularis. Similarly, with reference to the femur no notice is taken of the value of the diameter of the head or of the bicondylar width as a guide to sex.

The old nomenclature is used for the most part, but new terms are used here and there, apparently by chance. In the description of the muscles on the back of the forearm, new names are used in two cases (*extensores pollicis brevis* and *longus*), but the older term is retained for the *abductor pollicis longus*. There is an appendix which deals with nomenclature. The person who drew it up was apparently under the impression that the Basle nomenclature in many cases only turned the English name into dog Latin. This portion has many errors which could have been avoided by reference to the official glossary. Important changes are not referred to at all; for example, there is no mention of the radial nerve being the new term for the musculospiral. The glossary, which gives the meaning of many technical terms strange to beginners, is a useful addition. The book is a good one, but could be improved by careful editing.

LITERARY NOTES.

WE have received a copy of "The Medical Who's Who" (Fulton Manders Publishing Co., 75, Chancery Lane, London, W.C. Fifth year, 1916. Price, 10s. 6d. net), stated to cover the period March 1916 to March 1917. To judge by the increase in size, the volume is appreciated. Last year it contained 1,000 pages, this year 1,200. It gives biographical details of 15,000 medical practitioners. Forms were sent to all names appearing on the Medical Register and supplementary lists, and "The Medical Who's Who" contains the information as supplied, presumably by the recipients of the forms. It should be observed that "The Medical Who's Who" is not a list of the "big pots" of the profession. The policy of the publishers is to include the names of all doctors who supply particulars and return the forms sent.

The work is therefore not a limited list of injudicious selection.

The particulars are included free from any condition.

(a) "Manual of Anatomy, Systematic and Practical, including Embryology." By A. M. Buchanan, M.A., M.D., C.M., F.R.F.P. and S.Glasg. With 675 illustrations. Third edition. Demy 8vo. Pp. xii. and 1743. University Series. London: Bailliere, Tindall and Cox. 1916. Price 21s. net.

The present publication includes details of medical and nursing periodicals.

The type is clear and easily read, and the book will be found convenient for reference.

* * *

VOLUME II. of the "Dublin University Calendar" for the year 1915-1916 (Dublin: Hodges, Figgis and Co., 1916) consists chiefly of lists of names of prize-men and honour men and recipients of degrees, together with the rolls of present members of Trinity College, of the Senatus Academicus, and of University Electors. It is not more accurate than other academic year-books. The roll of electors gives much strange information. For instance, from page 304 we learn that Newry is in Co. Louth (the *Daily Mail* recently placed it between Kildare and Dublin). On page 262, a well-known London barrister is described as "Rev.," and his address is given as "Rathmines, Dublin." More surprising still is the description on page 298, of one of the best-known Dublin obstetricians as "Chief Justice Sierra Leone."

MEDICAL NEWS IN BRIEF.

Walsall M.O.H. and his Recruiting Fees.

At Walsall Town Council meeting on 8th May Dr. Lynch drew attention to a statement in the report of the General Purposes Committee that it had been decided to allow the borough medical officer of health (Dr. Shore) to retain the fees which he received for the examination of recruits under Lord Derby's scheme. He proposed as an amendment that the subject be referred back until some information was available as to the total amount of the fees. He said he did so on the ground that the money belonged as much to the ratepayers as did the fees received for letting the Town Hall.

Mr. Lester seconded the amendment, but Dr. Layton, who mentioned that he was secretary of every medical institution in the town, denied that the practitioners as a body had raised any objection to Dr. Shore earning these extra fees. Much of the work was done by him long after office hours, and frequently he was engaged until midnight. The work was of a particularly strenuous nature, and it was simply undertaken by Dr. Shore because the practitioners of the town were unable to undertake it.

Alderman Pearman-Smith said that, strictly speaking, these fees should no doubt be paid into the borough fund, but the Council took the view that they were earned under abnormal conditions, and that the work was undertaken at the request of the military authorities.

Mr. Tucker added that it would be mean and contemptible if the Council attempted to "purloin" these fees.

The amendment only received three votes, and the recommendation was agreed to.

Lady Doctor for Hyde.

THE Hyde Town Council on 8th May decided to appoint a lady doctor at a salary of £350 a year as medical officer for the Education Committee and for the Maternity and Child Welfare Committee.

The discussion disclosed a strong feeling in favour of taking action to protect child life, but several members urged that, with some of the Hyde medical men serving in the war, the present was not an opportune time for creating new appointments for which they had no chance of applying.

Soldiers and Drugs.

THE following Order has been made by the Army Council under the Defence of the Realm (Consolidation) Regulations, 1914:—

No person shall sell or supply any article specified in the Schedule to this Order to or for any member of his Majesty's Forces unless ordered for him by a registered medical practitioner on a written prescription, dated and signed by the practitioner with his

full name and qualifications, and marked with the words, "Not to be repeated," and unless the person so selling or supplying shall mark the prescription with his name and address and the date on which it is dispensed. Schedule.—Barbitone, benzamine lactate, benzamine hydrochloride, chloral hydrate, coca, cocaine, codeine, diamorphine, Indian hemp, opium, morphine, sulphonal and its homologues, all other salts, preparations, derivatives, or admixtures prepared therefrom or therewith.

Royal College of Surgeons of England.

At the Primary Examination at the Royal College of Surgeons of England for the Fellowship in Anatomy and Physiology, held on May 3, 4, and 9, 34 candidates presented themselves, of whom 11 were approved and 23 were rejected. The following are the names and medical schools of the successful candidates:—F. C. Alton, M.B., B.S.London, M.R.C.S., L.R.C.P., G. V. W. Anderson, J. M. Bickerton, H. B. Bullen, B.A., Dorothy Gilford, R. B. Green, A. J. McNair, M.B., B.C.Cantab., M.R.C.S., L.R.C.P., L. M. Moody, R. J. Perkins, H. B. Russell, and J. Victory.

Falling Cambridge Funds.

The Financial Board of Cambridge University, in an estimate of income and expenditure for 1916, state that the income of the University Chest, which is derived mainly from fees, was £53,401 in 1913, £46,812 in 1914, and last year £33,704—or over 30 per cent. less than in 1913. They estimate that the income for 1916 cannot be expected to exceed £21,550.

As against this, the normal charges on the Chest for the present year are expected to amount to £37,750, showing a deficiency of £16,200. The Board propose to transfer certain sums from the Common University Fund, which is almost entirely made up of contributions from the colleges, reducing the deficiency at the end of the year to £5,200.

Although the colleges are almost depleted of students, they have increased their contributions to the Common University Fund from £23,796 in 1914 to £25,706 in 1915. The estimated receipts of this fund for the present year amount to £29,356, and the estimated expenditure to £16,000, leaving a balance of £13,356; but of this £9,500 will be required in 1917 to meet charges which fall to be paid before the income of 1917 is available.

The Local Examinations and Lectures Syndicate are prepared to contribute from the fund at their disposal £2,000 for general University purposes in the present year. The Board recommend that this sum be applied towards reducing the debt of £7,522 on the Examination Rooms Building Account.

Doctors ask Higher Allowances.

THE doctors who give their services to the members of the Kirkintilloch and Twechar Miners' Association have sent in a representation for increased allowance for professional attendance on the miners' wives and families. At present each worker, whether married or single, contributes 2d. per week for the doctors' fees. A great many of the unmarried men have joined the Colours, so that the amount for the doctors has been greatly reduced. The prices of medicines and locomotion have also increased.

Salisbury Spotted Fever Epidemic.

THE epidemic of cerebro-spinal fever among the British and Canadian troops in the Salisbury area in 1914 is the subject of a Local Government Board report.

Dr. R. J. Reece says:—

"The outbreak in the city of Salisbury commenced on December 15, 1914, with the case of a hospital nurse. There were no cases at that time known to exist in the city of Salisbury. But it was reported after the nurse's death, which occurred in 24 hours after the onset of the disease, that she was frequently in the company of a young officer of the Canadian Expeditionary Force, to whom she was said to be

engaged to be married, and after many inquiries this officer was visited and a swab was taken from his throat. The cultures showed infection of his throat with the meningococcus. In the circumstances, and lacking any other known source of infection, it does not seem unreasonable to suppose that the earliest known of the cases that occurred in the outbreak in this epidemic had its origin from this officer."

Metropolitan Hospital, London.

At the annual meeting of the Governors of the Metropolitan Hospital, Kingsland-road, last week, Mr. T. Dyer Edwardes, in moving the adoption of the report, stated that during the past year the in-patient accommodation had been increased to three times its former size, in order to find room for sick and wounded soldiers. Of the 360 beds, 260 were for military patients, which included the Howard de Walden wards provided at a cost of £2,000 by Lord and Lady Howard de Walden. The year had been a very trying one from a financial standpoint, and while the expenditure had amounted to £19,331, the income had only reached £16,696, leaving a deficit of nearly £3,000. He trusted that that deficit would be cleared off during the current year.

German Army Medical Statistics.

ANOTHER Army Medical Congress was held last week at Warsaw. The chief German representative, Professor von Schjerning, provided some new statistics. He said that 24,000 doctors were in the service of the Army—three-quarters of them in the field, and one-quarter at home. There were 3,000 doctors working with the Red Cross, 400 dentists, 1,800 chemists, and 92,000 men in the medical services. The voluntary nursing service employed 72,000 persons in Germany and 22,000 on the lines of communication. There were 238 hospital trains taking wounded and sick back to Germany from the hospitals near the front. They had 26 large steam laundries on the lines of communication, and on the frontier there were 18 large disinfection establishments dealing with 100,000 men a day.

Birmingham Doctor's Arduous Labour.

A DOCTOR who applied at the Birmingham Tribunal on 8th May for exemption for his chauffeur said he had unsuccessfully tried to replace the man. He had a panel of 3,000 patients in a munitions area and would far sooner join the Colours himself than keep on with his present work, which was "simply killing." The chauffeur was granted exemption for a month.

Hospital Economy.

IN the interests of economy, the council of the Charing Cross Hospital consider that the extensive printing of the annual report (which costs between £250 and £300) should be abandoned. A certain number will be printed, and on the application of any subscriber who wishes to have one a copy will be posted to him.

Water Purification.

AT a meeting of the Metropolitan Water Board on May 12th, the Water Examination Committee reported that experiments conducted in the Board's laboratory in the economical purifying of water had been so satisfactory that it had been decided to test the method under actual working conditions for a month at a cost of £360.

Women Doctors.

THE incursion of women into the ranks of the medical profession began, of course, long before the war. But the war has undoubtedly been a great stimulus to the movement. Exact figures are not available, but there seems to be no question that an increase measuring, it is said, in some instances, 50 per cent., has occurred in the ranks of women students. The same thing applies to women dispensers, who are naturally in great demand at the present moment. Meanwhile women doctors are doing men's work in many directions.

Concession to Welsh Medical School.

COLONEL E. M. BRUCE VAUGHAN made an interesting announcement with regard to the progress of the Welsh Medical School at a meeting of the King Edward VII. Hospital Committee on May 10th, when General H. H. Lee presided. He said that Mr. McKenna had caused the plans of the complete medical school to be approved, and had intimated that he would not stand in the way if the assent of the Minister of Munitions could be obtained to the building of the public health department.

Colonel Bruce Vaughan paid tribute to the splendid spirit in which the members of the honorary medical staff had approached the subject.

A committee was appointed, consisting of Dr. Rhys Griffiths, Dr. Mitchell Stevens, Dr. Ewan Maclean, Colonel E. M. Bruce Vaughan, the Rev. Canon David Davies, and one member of the special department, to nominate who should give evidence before the Royal Commission when required.

Enemies' Medical Supplies.

SIR M. DE BUNSEN, in a statement to the Associated Press with regard to the conveyance from America to the Central Powers of medical supplies, says that the British Government, while prepared to allow the despatch of medical supplies to any American Red Cross units which may be working for the Central Powers upon receipt of assurances as to their employment, is not prepared to allow medical supplies to be generally imported by the enemy. A general permit to import these supplies would mean that the enemy would be able to draw large quantities from all parts of the world, and that they would be free from all necessity of using their existing supplies of such articles as rubber for medical purposes and to devote them exclusively to war-like ends. If the enemy suffered from a shortage of certain commodities for medical purposes owing to the demands of the military services their remedy, if they wished to safeguard the interests of their wounded, was obviously, the statement concludes, first of all to allocate a sufficient amount of available supplies to these purposes.

In the Franco-Prussian War the Germans did not allow medical supplies to enter Paris, and in the present war they have prohibited the export of German medical books, because they openly profess to grudge to other countries the benefits of German scientific skill. Their submarine blockade is avowedly intended to cut off all supplies to Great Britain, and Germany has deliberately violated the Geneva Convention by attempting to torpedo the hospital ship *Asturias* and by actually torpedoing the hospital ship *Portugal*, thereby causing the deaths of a large number of nurses and helpless wounded men. Charges of inhumanity from those who have done such things should be closely scrutinised. As to the legal right of the Allies to intercept medical supplies there can be no doubt.

The Asylum Workers' Association.

THE annual general meeting of the Asylum Workers' Association will be held to-day (Wednesday), May 17th, at 3 p.m., in the rooms of the Medical Society of London, Chandos Street, Cavendish Square. The chair will be taken by Sir John Jardine, Bart., K.C.I.E., M.P., LL.D., President of the Association. The Asylum Workers' Association was founded in 1895, to promote the interests and welfare of asylum nurses and attendants, and of others engaged in nursing the insane, and thereby improve their professional status in the nursing world. The membership has now reached 2,626.

Assistance for Reserve Medical Services.

THE Secretary of the War Office makes the following announcement:—It has been suggested that benevolent societies should be formed for the benefit of the families of officers and other ranks of the medical services auxiliary to the Regular Royal Army Medical Corps—namely, the Special Reserve, the Territorial Force, and the new armies. A meeting, presided over by the Director-General, will be held in the Lecture Theatre of the Royal Army Medical Col-

lege, Grosvenor Road, London, S.W., on Thursday, June 1st, at 2.45 p.m., and it is hoped that as many officers as possible will attend.

Factory Surgeons and National Economy.

THE Home Secretary (Mr. Herbert Samuel) received at the Home Office, on May 5th, a joint deputation from the Incorporated Association of Certifying Factory Surgeons and the British Medical Association, who protested against the following recommendation in the final report of the Committee on Retrenchment in the Public Expenditure: "We understand that the reports of certifying surgeons on accidents, which cost £12,500 per annum, are now of little value, and entail in all serious cases a duplication of the reports made by the inspectors. The Committee on Accidents in Factories recommended that legislation should be obtained to enable them to be dispensed with, and we concur in this proposal."

Mr. Samuel replied that there was a great demand for doctors' services in every direction arising from the withdrawal of a great number of medical men from civil work to undertake military work, and this was specially a time when it was difficult to justify continuing to require a number of doctors all over the country to spend time in making reports which had been declared by an investigating committee to be superfluous. He would lay before Parliament shortly a Bill dealing with similar points of economy in connection with the Home Office, and if he did not include the one to which the deputation referred his position in the House of Commons would be somewhat remarkable. He had considered the memorial sent in by the Association, and it had not convinced him.

Milk and Health.

THE Lord Mayor of Sheffield (Councillor F. A. Warlow), presiding at the annual meeting of the Children's Hospital on April 14th, made a strongly worded reference to the growing practice of adulterating milk, which had been brought before the City Council. He said that when he looked ahead, and considered the great wastage of the young life of the Empire that was taking place, the great importance of looking after the child life was brought home to us more than ever. The enormous increase in the milk adulteration of the city was a matter of considerable importance. "It is our duty," said his lordship, "to prosecute as far as we possibly can a war against this infamous adulteration, and no steps will be neglected to stamp out this crime in our city." He added that he scarcely thought that the people who were responsible for the adulteration realised what they were doing, because the practice was not only a fraud, but had a deplorable effect upon child life, by robbing them of the most nutritious part of the milk.

Hooks in Preserved Meat.

AN Italian Army doctor, a member of a well-known Anglo-Italian family, who is now serving on the Italian front, writes as follows:—

We are obtaining every day more striking evidence of the appalling methods of German Kultur. We have discovered tiny steel hooks of microscopic size in tins of preserved meat from America. We have had naturally to stop at once the use of this stock.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad. Foreign subscriptions must be paid in advance. For India Messrs. Thacker, Spink and Co., of Calcutta, are our official

appointed agents. Indian subscriptions are Rs. 15.12. Messrs Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THERAPEUTIS.—The article has come to hand; as soon as space and other arrangements allow, we shall be glad to publish it.

A USEFUL HAND.

At Bow County Court last week, it was stated that a one-handed casual labourer had been earning 11s. 6d. a day at the docks.

DR. S. H. C.—Recent investigation seems to indicate that alcohol interferes with the elimination of uric acid, leading to the retention of the latter—unoxidised—in the tissues.

A PANEL DOCTOR'S TRIALS.

A PANEL doctor sent a letter to the judge at Westminster County Court on May 9th, saying he would pay two judgment summonses as soon as he got the balance of money due for 1914 and 1915 from the London Insurance Committee.

EXCELSIOR (Birmingham).—We regret having overlooked our correspondent's query. The reply is in the affirmative, subject to the approval of the MS.

DR. SEQUEIRA.—Regret the note arrived too late for insertion.

RACECOURSE MILITARY HOSPITAL.

THE five-shilling stand at Ascot, closed several weeks ago for painting and other improvements, has been reopened as a military hospital.

M.R.C.S., L.R.C.P. (Leeds).—We have ascertained that the book is now out of print, but a new edition is being prepared.

EIGHTEEN CHILDREN IN EIGHT YEARS.

DR. J. S. DORSEY, of Langon, D.C., reports the birth of 18 children in eight years as follows:—First birth, single; second birth, twins; third birth, triplets; fourth birth, twins; fifth birth triplets; sixth birth, twins; seventh birth, triplets; eighth birth, twins. Mother 32 years old at last birth. All lived to be 20 years old, then died.

DR. I. G. C. is thanked for his paper, which is marked for early insertion.

SUMMER TIME.

At Overslag, a village partly in Holland and partly in Belgium, "summer time" is causing great confusion. The church is on Belgian territory, and the tower clock indicates German summer time, but in the church itself the old Belgian (Greenwich) time is still observed. The Dutch officials follow the new Dutch summer time, and in the Dutch school the time differs by an hour from the German summer time. At the same hour, therefore, the tower clock shows 2 o'clock, the clergyman's watch 12, the school clock 1, and the Dutch officials' clock 1.20.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 17TH.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—Paper—Mr. J. W. Purkiss: Some Suggestions Regarding Visual Efficiency in the Use of the Microscope and other Optical Instruments.

THURSDAY, MAY 18TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Exhibition of Cases (at 4.30 p.m.): Cases—Dr. George Pernet: (1) Tertiary Syphilis in a Woman treated by Intramine; (2) Urticaria Pigmentosa in an Infant. Dr. Graham Little: (1) Parakeratosis Variiegata; (2) Lichen Scrofulosorum with Scrofuloderma.

FRIDAY, MAY 19TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOLOGY) (1 Wimpole Street, W.).—5 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Cases and Specimens will be shown by Mr. J. S. Fraser, Sir William Milligan, Mr. Sydney Scott, Mr. W. M. Mollison, and others. Mr. W. M. Mollison: A Note on the Monochord.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS AND PHARMACOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Exhibition of X-Ray and Electro-Medical Apparatus, Radiographs, Lantern Slides, etc., will also be exhibited. Members wishing to show Plates, etc., will kindly communicate as soon as possible with Mr. S. Gilbert Scott, 6 Bentinck Street, W.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—5.30 p.m.: Paper—Major J. M. Atkinson, R.A.M.C.: Cerebro-spinal Fever, with the Notes of Some Cases. Dr. A. C. Stevenson will show some Specimens of Nodules in Lung from a Case of Morphia Injectors' Septicæmia (Whitmore's Disease), and Cultures of a Bacillus isolated from the same.

MONDAY, MAY 22ND.

ROYAL SOCIETY OF MEDICINE (SECTION OF ODONTOLOGY) (1 Wimpole Street, W.).—8 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Paper—Dr. J. Howard Mumery: The Structure and Arrangement of the Enamel Prisms, especially as shown in the Enamel of the Elephant.

TUESDAY, MAY 23RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE) (1 Wimpole Street, W.).—5.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917.

Vacancies.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Assistant Resident Medical Officer. Salary £150 per annum, with board, residence and laundry provided. Applications to George Watts, Secretary.

Borough of Lewisham.—Tuberculosis Dispensary Medical Officer. Salary £250 per annum. Applications to Edwd. Wright, Town Clerk, Town Hall, Catford, S.E.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with board, rooms, attendance and washing. Applications to the Secretary.

Belfast Municipal Sanatorium.—Assistant Resident Medical Officer. Salary £200 a year, with board and residence at the Sanatorium. Applications to Town Clerk's Office, City Hall, Belfast.

Birmingham General Dispensary.—Resident Medical Officer. Salary £250 per annum, with furnished apartments, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary, 32 Union Street.

Borough Hospital, Birkenhead.—Junior House Surgeon. Salary £170 per annum, with board and laundry. Applications to the Secretary.

St. Bartholomew's Hospital, Rochester.—Clinical Assistant. Salary £110 per annum, with board, residence, and laundry. Applications to the Secretary.

Nottingham General Hospital.—Assistant House Surgeon. Salary £250 per annum, with board, residence, and laundry in the Hospital. Applications to the Secretary.

Beckett Hospital and Dispensary, Barnsley.—House Surgeon. Salary £250 per annum, with apartments, board, and laundry. Applications to R. F. Pawsey, Honorary Secretary.

Appointments.

GROSE, JOHN SOBRY, L.R.C.P.Lond., M.R.C.S., Medical Officer and Public Vaccinator for the Abbotsham, Buckland Brewer, and Bideford Districts, and Medical Officer to the Workhouse, by the Bideford (Devon) Board of Guardians.

HAY, PERCIVAL J., M.D., Ch.B.Edin., Honorary Ophthalmic Surgeon to the Sheffield Royal Hospital.

HUXLEY, FRANCES M., M.D.Vict., Assistant Surgeon to the South London Hospital for Women.

MACKENZIE, LEWIS, F.R.C.S.Eng., L.R.C.P.Lond., Acting Tuberculosis Medical Officer for the Borough of Barnstaple (Devon).

PEARSON, ELLIS, F.R.C.S.Edin., L.R.C.P.Edin., Medical Officer for the Milton District by the Barnstaple (Devon) Board of Guardians.

UMANSKI, AUGUSTA, M.B., B.Ch.Leds., Assistant Medical Officer to the Infectious Diseases Hospital, Seacroft, Yorks.

Births.

BAHR.—On May 9th, at 12 Vicarage Gardens, Kensington, W., the wife of Captain P. H. Bahr, R.A.M.C., of a son.

BYAM.—On May 5th, in Cairo, the wife (*née* Stiven) of Major Wm. Byam, R.A.M.C., of a daughter.

NEWSHOLME.—On May 7th, at 20 Lingfield Avenue, Kingston-on-Thames, the wife of Lieutenant Henry Pratt Newsholme, R.A.M.C., of a son.

Marriages.

GRIFFIN—PINN.—On May 4th, at the Congregational Church, Snarebrook, Captain Cyril J. A. Griffin, R.A.M.C. (S.R.), son of the Rev. C. Griffin, Auckland, New Zealand, to Jessie Elizabeth, daughter of the late William Pinn, Port Elizabeth, South Africa.

PASLEY—ELLIOTT.—On May 8th, at St. Mary's, West Kensington, Claude John Burgoyne Pasley, M.R.C.S., West African Medical Staff, son of the late N. C. Burgoyne Pasley, M.R.C.S., Trinidad, B.W.I., and Mrs. Pasley, of 3 Argyll Mansions, Kensington, to Blossom Emily, youngest daughter of the late Major William Elliott, Royal Artillery, and Mrs. C. A. Herbert, of 25 Richmond Place, Brighton.

WILLIAMSON—BOMFORD.—On May 6th, at St. Nicholas, Sutton, Surgeon David J. Williamson, R.N.V.R., to Joan, daughter of Mrs. Woodburn J. Bomford, of Sutton.

Deaths.

HARRISON.—On May 5th, suddenly, at Belize, British Honduras, the Hon. Dr. J. H. Hugh Harrison, J.P., F.R.G.S., M.R.C.S., Principal Medical Officer, Member Legislative Council, British Honduras, aged 52 years.

ROE.—On May 6th, at Ellesmere, Shropshire, John Withington Roe, M.D., in his 86th year.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

**Whistling
for
Taxis.**

THE ways of the law are indeed inscrutable. For quite twelve months I have been inveighing against the selfish and inconsiderate practice of whistling for taxicabs. In December last the readers of the *Times* took the matter up and the correspondence columns of the leading daily bore witness to the general feeling of indignation which the practice aroused. Then ensued a silence. On Monday, May 15th, the matter was reopened by a letter which begins as follows:—"A few days ago Mr. Paul Taylor, the Magistrate at the Marylebone Police Court, in imposing a fine of 5s. on a hotel porter charged with persistently using a cab whistle within a hundred yards of eight nursing homes and hospitals, is reported in the *Times* to have said that he had seen many complaints about whistling for cabs, but if those who complained would tell the public how it was to be avoided their letters would be more instructive than they were."

**The
Remedy.**

MR. PAUL TAYLOR must be singularly devoid of imagination. In the very act of applying the deterrent, he asks how the offenders are to be deterred.

It is true that a fine of five shillings is probably a mere trifle to the opulent people who thoughtlessly inflict this particular irritation upon their unfortunate neighbours, but that could be remedied by a stroke of the official pen. The mere fact of being summoned to appear before a magistrate to answer a charge of this kind cannot be a pleasant experience to anyone with self-respect; and if the real offenders, the employers, were summoned, instead of the porter who is only obeying orders, and if it were known that the employers would in future be so summoned, a very little activity on the part of the police would speedily put an end to the nuisance. The interesting and instructive point emerging from the proceedings in Mr. Paul Taylor's Court is that there exists a statute under which these disturbers of the peace can be summoned and, in some degree, punished. Let the police continue their beneficent activities, and before long the weary will be able to sleep.

**Panel
Medico-Political
Union.**

THE letter from Dr. Weply, of the Panel Medico-Political Union, which appears in our correspondence column, is an interesting pronouncement which clears up at least one point which before appeared ambiguous. He says that "any duly qualified medical practitioner within the meaning of Section 34 of the Medical Act, 1858, is eligible for membership of the Panel Medico-Political Union. I know very little about the Union, and naturally concluded that its name described it correctly. It now seems that the Union is really more inclusive than its name would imply, a fact which is of very considerable importance to those members of the profession who are not on the Panel. I venture humbly to suggest to Dr. Weply and his coadjutors that the word "Panel" should be removed from the title of their Union, so that doctors who are wise enough to hearken to the warning words which I have written in these columns may not be discouraged by a mere name from joining a young, vigorous and watchful organisation, which has the power to defend their interests.

**The
Menace.**

DR. WELPLY estimates the number of panel doctors at 15,000, that is, at roughly one-half of the effective members of the profession in the British Isles. Of the remaining 15,000 a great many are actually or prospectively engaged in work which brings them directly or indirectly in contact with the State; parish doctors, medical officers of health, tuberculosis officers, medical officers in the Naval and Military Services, and the like. If the schemes for the establishment of children's clinics, maternity clinics, venereal clinics and other public services, which are now so much discussed are to take practical shape, a great many more doctors will be brought within the cribbing and confining influence of State regulations: and when the proposals for nationalising the hospitals materialise, as materialise they most certainly will, those who still remain outside that influence will be duly roped in. The next medical Bill which, so far from being *in nubibus*, is already in being, will propose very drastic changes in the conditions under which professional work is at present carried on,

and unless the profession is sufficiently well organised to defend its own interests, it will be enslaved. There is no other word for it.

The Defence.

If medical men imagine that their interests are safe in the hands of the older institutions or associations they are woefully mistaken. In the fight over the Insurance Bill, the Royal Colleges stood disdainfully aside—how could they interest themselves in anything so vulgar as contract practice?—and the only Association which might be supposed to have the necessary knowledge and organisation, the British Medical Association, behaved precisely as those who knew it best expected it to behave—namely, like a set of bungling, self-satisfied noodles who had as many policies as there are raisins in a plum-pudding—always changing and always wrong. The result was what we now know it to be. One satisfactory issue from this orgy of peddling prejudice and rancorous incompetency has been the birth of a Union whose business is entirely medico-political, and I sincerely hope that Dr. Weply will be able so to arrange matters that every member of the profession, including women, will be able to take advantage of the new organisation which has for its laudable object the safeguarding of our interests *vis-à-vis* the sweating tendencies of mere politicians.

THE latest exploit of the British Medical Association, *re* the notification of measles, to which I referred in our issue of May 3rd, has called forth a correspondence between Dr. F. J. Smith and Mr. Bishop Harman. This has been sent to us for publication by the last-named, and will be found in another column. Dr. "F. J.," whose originality and independence of thought have endeared him to a very wide circle in the profession, writes: "Is it true that the deputation from the head office of the B.M.A. to the L.G.B. admitted that one shilling would be a sufficient fee for notification of infectious disease?" To which Mr. Bishop Harman replies that the statement is not true. Mr. Harman is well within his rights in thus replying in the negative, especially as he goes on to confess that such an admission was actually made in the case of one particular infectious disease—namely, measles. Mr. Harman's apologia for making this admission, which naturally drew from the L.G.B. the unanswerable retort, "If measles is only worth one shilling, why not all the others?" makes curious reading. It exposes a truly British Medical mentality.

A War Economy.

"But we made it clear," says this wily diplomat, "that any exceptional fee for measles was to be considered only as a reduction on taking a quantity" (a worthy and dignified professional attitude) "and a war economy concession, and not the concession of the professional position." To talk about a war economy concession in discussing a question of principle which has no more to do with the war than it has to do with the Vatican, is as stupid and mischievous an irrelevancy as could possibly be found even in

the annals of the British Medical Association; while the statement that there was no "concession of the professional position" displays a degree of muddle-headedness which is seemingly the monopoly of the middle-class wits at 429, Strand. The lady who, "swearing she would ne'er consent, consented," was probably related to, even if she were not identical with, the one who excused her illegitimate baby on the ground that it was "only a little one." The psychology of the representatives of the British Medical Association appears to be identical with that of these two historical damsels.

The King's Evil.

DR. PHINEAS ABRAHAM, in giving evidence in the leprosy case, told the judge that leprosy "was known as the 'King's Evil,' and was supposed to be cured by the touch of the King." Dr. Abraham ought surely to have known better. The King's Evil was a scrofulous condition. Dr. Johnson suffered from it, and was duly touched for it by Queen Anne in 1712. Among the counts in the indictment against the ill-fated Duke of Monmouth was one that he had dropped the "bend sinister" from his coat of arms and another that he had touched for the King's Evil. The practice of touching for morbus regis is erroneously said to have originated with Edward the Confessor. It was in reality brought from France by Edward III., who borrowed the practice from the French King over whom he had been victorious. "Les rois de France passaient pour guérir les écrouelles." A few years ago Professor Landouzy issued an interesting pamphlet on the subject on which I am unfortunately unable to put my hand, but in his *Glossaire Médical* (C. Naud, 1902) he describes écrouelles as "Adénite tuberculeuse du cou." The King's Evil was certainly not leprosy. Boswell says "Young Johnson had the misfortune to be much afflicted with scrofula, or the King's Evil," and then proceeds to tell the story of the "touching."

Another War Economy.

MR. R. J. ANGEL writes to the *Daily Chronicle* from the Engineer's and Surveyor's Department, Town Hall, Bermondsey, to call attention to a very serious menace to the health of the people of London, which ought to be emphasised and insisted upon by every medical man in the metropolis. Mr. Angel says: "I notice that certain London boroughs have decided to abandon the washing and watering of their roads, thus effecting a war economy. May I point out that this is one of the worst things that can happen to the metropolis. The dust and dirt of our roads consist of nothing less than dried sewage, possessing all the ingredients of disease and infection, and it has been proved over and over again that this dust, when blown into people's faces and into food shops, has been the cause of disease and ailments peculiar to hot weather. There are other ways of effecting economies than neglecting the cleansing of our streets." I hope that medical men resident in these offending boroughs will at once protest against this form of "economy." Nothing could be more shortsighted or unimaginative than the ordinary British Bumble, and he is here seen in his favourite and most characteristic occupation of pledging the prospective prosperity of posterity for a few present pence.

SINAPIS.

OF HORMONES, AUTACOIDS, CHALONES, ET ID GENUS OMNE.

THOUGH it may be true that under the sun there is nothing new, there are nevertheless certain aspects of things true, which are so new, that strange verbal garments are necessary for their expression. Around such meagre knowledge of the activities of the ductless glands as we have already amassed there has grown up a vocabulary which is impressive and portentous, and it is still growing. The group of ductless glands themselves have been christened, rechristened and christened again, and the wake of each fresh ceremony has been strewn with adjectival and adverbial adventures most disconcerting to the workaday mind. The glands whose internal secretions were recognised as potent "regulators of metabolism" were found to include some which were not ductless, and the whole group was called internal secretory. Brevity then demanded something less cumbersome, and "endocrinous" was invented. This became "endocrinic," and is now not infrequently "endocritic." The latest and most authoritative work on the subject is entitled "The Endocrine Organs," (a) and it is here that we assist at the birth of the autacoids and chalones.

"Since the most characteristic feature of the action of these substances is the resemblance to the action of drugs, such as the vegetable alkaloids, I propose to employ for these specific substances the general title 'autacoid substances,' or, simply, 'autacoids' (*αὐτός*, self, and *ἄκος*, a medicinal agent or remedy). I would accordingly define an autacoid as a specific organic substance formed by the cells of one organ, and passed from them into the circulating fluid to produce effects upon other organs similar to those produced by drugs. Such effects are either in the direction of excitation, in which case the endocrine substances producing them are 'excitatory autacoids' and would come under the expression 'hormones,' or in the direction of restraint or inhibition, in which case they are 'restraining' or 'inhibiting autacoids,' and would be classed as 'chalones.' The action of an autacoid may therefore be described as 'hormonic' or 'chalone,' according to the kind of effect it produces."

This is Sir Edward Schafer's contribution to the nomenclature of the new physiology which has been opened up by the study of the behaviour of these internal secretory organs, and, like the book in which the passage appears, it is essentially sane, helpful and orderly. Much has been written on this fascinating subject during the last ten years, of which it may be said that perhaps its most salient feature is the number of bewildering and contradictory statements which it contains. To attempt to follow the recent literature is to subject your brain to the experiences of a shuttlecock which is buffeted from one battledore to another until it falls featherless to earth. After such stupefying aerial adventures, endured over a protracted period,

(a) "The Endocrine Organs." By Sir Edward A. Schafer, F.R.S., Professor of Physiology in the University of Edinburgh. London: Longmans, Green and Co., 1915.

the relief to find yourself once more on solid ground is quite inexpressible. For it is the solid ground of our present knowledge, carefully epitomised and lucidly expressed, which the learned Edinburgh professor offers the reader in these 150 clearly printed pages. The book is founded on some lectures delivered at Stanford University, California, and does not pretend to be exhaustive. Its great merit, transient though that merit must necessarily be, is that it enables the student of the subject to pause, to take breath, and to adjust his vision while the magician's hand for an instant stays the machinery and bids the moving pictures be still.

In the case of so large a subject compressed into relatively so small an area—the book is full of illustrations—some of the component parts must necessarily suffer neglect. Of thyroid and parathyroid, of pituitary, of suprarenals, the accounts are delightfully succinct and satisfying; but of pancreas, spleen and gonads the whetted appetite craves for more. The gonads—*i.e.*, the testicles and ovaries—are developmentally perhaps the most important of all the endocrine glands, for, in their relations to sex characteristics both physical and mental, they hold the key to many large and burning social and political questions which still await solution. Sir Edward Schafer, as becomes his professional status, gives us physiology pure and simple; with philosophy, in these pages at any rate, he has no truck. But the reader who is in search of light and guidance on these questions need not despair. He has only to travel from Edinburgh to Liverpool, where he will find Dr. Blair Bell in a physiologico-psychological mood, and will hear him discourse—clearly, eloquently and scientifically, with a courage which passes all praise—upon the subjects which Sir Edward Schafer avoids.

Dr. Blair Bell writes as a gynæcologist: "In the following pages our subject will be Woman, and I shall endeavour to make clear, so far as our knowledge allows, the difficult problem of the female sex complex in all its ramifications." The result of this endeavour is a book (b) which the author modestly calls a monograph, in which he discusses the morphology, physiology, pathology, and last but not least, the psychology of the female sex from the point of view of the influence of the endocritic (that is Dr. Bell's adjective) glands. The term "sex complex" he defines as "the correlation of the internal secretions in regard to the sex functions."

These two books are in a sense complementary the one to the other. Professor Schafer's is a general foundation, upon one angle of which, and that by no means the least important, or the least interesting angle, Dr. Blair Bell has raised a superstructure full of credit to the builder. A wise practitioner is he who endeavours to keep abreast of the "new physiology" which has been opened up by the internal secretions, and he will find no better, surer or more suggestive guides than the two latest British writers on the subject.

MISS FLORENCE SOPHIA JANE STODDON, of Chelsea, left £500 to the Coltishall Nursing Home.

(b) "The Sex Complex." By W. Blair Bell, M.D.Lond. London: Bailliere, Tindall and Cox. 1916. Price 12s. 6d.

CURRENT TOPICS.

Vivisection and the War.

At the annual meeting of the Research Defence Society held this month, an interesting address was delivered by Mr. Ernest W. Hey Groves, late Major, R.A.M.C., returned from a year's work in Egypt. He dwelt mainly upon the enormous benefit derived in Army hospitals from the results of experiments on animals. In illustration he quoted the well known examples of tetanus and enteric prophylaxis, and in parenthesis pointed out that very great benefit often results to animals themselves from this experimentation, most obvious, perhaps, in the prevention of tetanus amongst horses by means of inoculation. Statistics from a German hospital show that before the use of antitoxin the cases of tetanus numbered 14 per thousand of wounded men, whereas after its routine adoption the number of cases fell to 1.6 per thousand. Experience in the Allied armies has been somewhat similar. Mr. Hey Groves deplored the fact that owing to restrictions of vivisection it has not been possible to equip research laboratories in connection with the military hospitals in England. At Alexandria, where science is not so hampered, the research work has proved to be of the utmost value, especially in the important diagnosis of infecting organisms, of which those causing meningitis in cases of head wounds were especially instanced. He emphasised the urgency of these experiments in many cases requiring that the tests be made upon the spot, and he deplored the absence of logic in the minds of those people of one idea who would allow a surgeon to take into his hands the life of their nearest relative, but would on no account trust him to refrain from inflicting unnecessary suffering upon a rabbit or a cat.

Medical Men and the Irish Rebellion.

AMONG those sentenced to penal servitude by Field General Court-Martial in Dublin, whose sentence was confirmed by the General Officer Commanding-in-Chief, was Richard Hayes, who was sentenced to twenty years' penal servitude. This is Dr. Richard Francis Hayes, who was medical officer of the Lusk dispensary district, in County Dublin. He was arrested in the Swords district with a number of volunteers after the rising. He is a Licentiate of the Royal Colleges of Physicians and Surgeons of Ireland, having received his diplomas therefrom in 1905. The names of three Irish medical men have appeared in the list of prisoners deported to England pending trial. One of them is stated by the *Manchester Guardian* to have been arrested without cause while walking through the streets of Dublin. Another was arrested at his residence in the West of Ireland, while a third was arrested in the South of Ireland while on his honeymoon.

Physical Culture.

THE late President of the New Jersey State Board of Health publishes an interesting paper in a recent number of the *Medical Record* entitled "A Practical Scheme to Improve the Physique of Americans." He considers that work of this kind to be effectual must be started in the schools and amongst the smallest children. He would have in each city an examining board to examine and report upon the health and physique of the school children, and to award prizes for health and beauty. He would have in each school one fully qualified medical man or woman, according to the sex of the pupils, appointed for whole-time work. The duties of this person would be various—to instruct the teachers in

practical hygiene and physical culture, to superintend the sanitary and hygienic arrangements of the school, to regulate the games and athletic exercises, and thoroughly to overhaul each pupil once a month, drawing up a record of the physical development, of which record a duplicate should be sent to the child's parents with criticism and advice, and at the end of each year to award a prize to the child who has obtained the highest aggregate of marks at the monthly examinations. In addition to this the Board of Examiners should hold an annual examination at each centre, comprising tests of physical culture, and award medals and certificates to the best candidate. The scheme is thorough, it is worked out in detail, and, if applied, would certainly be of great benefit to the health of the populace. The chief objection to it is that the expenditure involved would be considerable, since it is stipulated that not only the medical attendant but also the members of the Board of Examiners should be liberally paid for their service. A simplified scheme upon these lines of regular physical examination of children, and providing a competitive interest, would undoubtedly be of great value if generally applied.

Petrol for Doctors.

MEDICAL men all over the kingdom have been suffering severely in regard to the supply of petrol for their motor-cars. It is not merely that the price has become high, but that there is an actual shortage of the article. Matters are bad enough in Great Britain, but they are much worse in Ireland. When the rising occurred in Easter week the military authorities at once commandeered the entire supply of petrol in the country, and traders were forbidden to sell any petrol to private customers. This measure was no doubt a necessary precaution at the moment, and we make no complaint of it. But although this restriction has now been removed, it is still impossible in many parts of Ireland to obtain any petrol. As a consequence many medical men in country districts find it impossible to travel the distances required of them for the performance of their duties, public and private. No section of the medical profession of the United Kingdom has responded more willingly to the call to service in the Army than the country doctors of Ireland, and the absence of so many has entailed a greatly increased mileage on their neighbours. Without an adequate supply of petrol it is impossible for the medical practice of the country to be carried on. The personal hardship on medical owners of cars is also to be considered; we know of one who has to pay high taxes on two cars and a motor-cycle, none of which he can take out of his garage. We hold that it is a plain duty for the Government, if the national supply of petrol is short, to prohibit its use for other than professional and business purposes. The burning of petrol for pleasure is, at the present moment, a national crime. The fine lady who takes her joy-drive of a fine afternoon is depriving the poor woman in the country cabin of the medical attendance she requires in her hour of suffering. It is for the Government authorities to put an end to this iniquity.

Malignant Scarlatina.

WE observe that Professor Hutinel, of the Paris Academy of Medicine, has lately given a very interesting account of his experience in this variety of scarlet fever. The malignant forms of scarlatina are of especial interest since the profession has become possessed of that extremely useful drug—adrenalin. During the year 1912-13, out of 417 cases of scarlet fever, 34 of which were of a malignant form, only nine ended fatally, whereas

in the preceding years 833 cases presented a mortality of 37 only. This means that the new treatment reduced the mortality by exactly 50 per cent. The malignant forms of scarlet fever may develop under various conditions, but in a general way they are more frequent in debilitated subjects. The elements for diagnosis are the following:—The rash is very intense, of a violet hue, and lasts longer than in ordinary cases. Besides the rash, there is an infectious erythema, occurring most frequently on the knees, elbows and buttocks. Sergeant's "white line" is nearly always present; sometimes there is a brownish pigmentation. Asthenia is often observed. The temperature attains 106°, and may be even higher. Death may take place before the appearance of the rash.

Watering the Streets.

In the stress of war, strange deeds are committed in the name of economy. The medical profession cannot but wonder at the type of mind which evolves some of the ideas already acted upon. The withdrawal of the grant for scientific research, the wiping out of factory surgeons' accident reports, the shilling measles notification, are all samples of the strenuous labour of the colossal official brain. We venture to think, however, that no proposal yet put forward shows greater shortsightedness or will work more havoc, than the suggestion referred to in our columns this week by "Sinapis" that during the coming summer the streets of London should not be watered and washed. The daily press teems with reports of meetings directed to the saving of infant life, yet it is no exaggeration to say that death will reap a rich harvest during the next few months if this monstrous proposal is put in force. The medical profession in this country is at present sadly depleted. It is difficult to cope with civilian practice, and it is the duty of the municipal authorities and of the Local Government Board to assist the profession in its untiring efforts to promote the health of the community. Dust is a fertile source of disease, carrying the germs of virulent infections. Dust must be combated. The streets must be watered. The driving of a watering cart is not a skilled occupation. Women, men beyond military age, convalescent discharged soldiers—any one of these could without difficulty undertake the duty. To leave the streets of London for months unwatered and unwashed is as safe a way of murdering children—and adults—as a British bayonet is of killing Huns.

Limited Enrolments in Medical Schools.

THE *Journal of the American Medical Association* gives some interesting details regarding the movement now in progress to limit the number of students enrolled in any one year by medical schools in the United States.

The Trustees of the University of Pennsylvania voted recently to limit the enrolment in the first and second year classes of the medical school to 100 students each. This is the fifth medical school in the United States to take action limiting its enrolment. Four years ago the Medical Department of Johns Hopkins University led the van by limiting the enrolment in its classes to ninety students each. Two years ago the Leland Stanford Junior University, School of Medicine, fixed the number at about twenty-five students in each class. Last year Rush Medical College fixed the limit at 100 students each in the first and second year classes and 120 students each in the third and fourth year classes. At the University of Minnesota the enrolment in the freshman class of the medical school has been limited to eighty students. This action was taken by each of

these medical schools in the belief that the limit fixed represented the largest number of students compatible with the most satisfactory medical training that could be furnished with the present organisation of its faculty and the capacity of its laboratories. A certain amount of individual instruction is necessary for the best results in medical teaching, and very few students are able to dispense with such individual attention if they are to attain a high degree of proficiency. The conclusion is that large classes lowers the standard of teaching for all students enrolled. If it become necessary to make provision for larger numbers of students, enlarged teaching facilities must be provided, preferably by establishing an additional teaching unit having its own faculty, laboratories, equipment and hospital facilities.

PERSONAL.

MR. D'ARCY POWER has been elected President of the Medical Society of London.

DR. ERNEST CLARKE will deliver a lecture on "Eye-sight and the War" at the Royal Institution on June 9th.

THE Society of Apothecaries of London (the Apothecaries' Company) has appointed Mr. Arthur Bingham Watson, of the firm of Messrs. Watson, Sons, and Room, of 12 Bouverie Street, E.C., to be Clerk to the Company.

THE Board of Trinity College has confirmed the nomination of Mr. E. H. Taylor, F.R.C.S., to the Regius Chair of Surgery in room of the late Sir C. Ball. Professor Taylor has been for the past nine years Professor of Surgery in Trinity College.

THE Bathgate Memorial Prize of the Royal College of Surgeons, Edinburgh, consisting of bronze medal and microscope, has been awarded, after a competitive examination in *Materia Medica*, to Miss Marguerite R. Stirling, and the Ivison Macadam Prize in Chemistry to Miss Janet Grant.

DR. WM. HANNA, Assistant Port Medical Officer, Liverpool, has been awarded the Henry Saxon Snell Prize of fifty guineas and the silver medal of the Royal Sanitary Institute, for his essay under the competitive title of "Suggestions for Improvements in the Sanitary Arrangements and Appliances on Board Ship."

DR. VINCENT J. GLOVER, M.D., who has been appointed medical officer of health and school medical officer for Waterloo and Seaforth, was a student of the former University College, Liverpool. He did pioneer work on the housefly as the carrying agent of the infection of infantile diarrhoea, which was the subject of his M.D. thesis. He also holds the appointment of hon. surgeon, Waterloo and District Hospital, Hotel Dieu, and police surgeon to the Seaforth and Aintree County Division.

PROFESSOR SIR GEORGE HARE PHILIPSON, M.D., F.R.C.P., of Newcastle, celebrated the attainment of his four score years on May 18th. Sir George's name is known far beyond the borders of Tyneside, and his work in connection with the Royal Infirmary, Newcastle, and Durham University has earned him the gratitude of the public generally. Sir George Philipson has received many honours—in 1893 President of the British Medical Association, Bradshaw Lecturer in 1884, Vice-Chancellor of Durham University 1912, President of the University College of Medicine, Newcastle, and a professor of medicine since 1876: a president of, and consulting physician to, the Newcastle Royal Infirmary; member of the General Medical Council, and a magistrate. He was knighted in 1900. His many friends will wish him further long years of usefulness and activity.

FRENCH CLINICAL LECTURE

ON

POSTERIOR FRICTION SOUNDS, ASSOCIATED WITH LARGE EFFUSION, IN THE PERICARDITIS OF BRIGHT'S DISEASE.*

By PROFESSOR CHAUFFARD,

Of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE diagnosis of pericardial effusion, which was formerly very uncertain, has become much more definite since the introduction of radiology. Pericarditis is still, however, a condition which is full of surprises, and its clinical signs demand a very close vigilance indeed. Friction of the most intense description may exist side by side with well-marked effusion. Moreover, the area over which friction sounds are perceptible is sometimes very large, involving regions where it is not customary to find, or for that matter to seek, them. These points are well illustrated by a case which recently came under my observation.

The patient, L., a young man, *æt.* 21, without pathological antecedents and with no signs of congenital syphilis, in May, 1915, developed bronchitis. There was albuminuria, slight dyspnoea after effort, vague precordial pain, and slight oedema of the lower limbs. During May, June and July the general condition remained practically unchanged, though the vision became impaired. In August there was a sudden increase in the anasarca and the visual disturbance became more pronounced. The patient visited the Quinze-Vingts Hospital, where his case was described as double albuminuric retinitis. He was put on to an exclusive milk diet, which did not, however, ameliorate his condition. The oppression and the precordial pain became worse, and there was insomnia, anorexia, and vomiting. He again went to the Quinze-Vingts, and, on November 1st, was from there sent as an in-patient to the medical clinic of Saint-Antoine.

At the time of his admittance, L. was pale in appearance, very oppressed, and compelled to adopt a sitting posture in bed; there was slight oedema of the lower limbs, the face was puffy, there was serous conjunctival chemosis, and almost total blindness. The urine contained 2.10 g. albumin to the litre, and the serum 1.72 g. urea in 1,000. Examination of the heart showed considerable extension of the area of dullness, and, on auscultation, a double pericardial friction-sound was observed. This was very marked—see-saw, almost staccato in character. It extended over the entire area of cardiac dullness, and at the level of the apex and above it the sound resembled the creaking of new leather. Pain was produced by pressure upon the diaphragm, especially on the left side. T.A. = 15/10.

In spite of venesection and liberal cupping, the sense of oppression and the pain in the precordial region continued for some days. The intensity of the pericardial sounds remained the same. On November 4th, an X-ray examination, to which I shall refer again later, was made, and I decided to puncture the pericardium. The puncture was performed on the following day by Marfan's method, by way of the epigastrium, 1,100 c.c.m. of a lemon-coloured liquid, slightly hæmorrhagic in character, being withdrawn without difficulty.

The patient appeared to be very much relieved by the puncture. He fell asleep two hours afterwards

and seemed to be less oppressed. He also somewhat recovered his vision, the T.A. rising from 13/10 before the puncture to 15/12 after it.

The improvement, unfortunately, was only transitory. The azotæmia became worse, and rose to 2.90 g. From November 8th the precordial pain returned; it was paroxysmal and agonising in character. Insomnia was complete.

On November 12th a second puncture was performed, and 350 c.c.m. of fluid were withdrawn. This liquid was more hæmorrhagic than the first, and its evacuation was followed by amelioration of very brief duration. During the entire period, the intensity of the friction-sounds remained the same, and on no occasion were they observed to be absent.

On the 14th, the agonising constrictive precordial pain became atrocious, and was relieved only by the injection of 5 mg. morphine. It was impossible to place the patient in a position which eased him, and during the night he died.

This unhappy clinical history is characterised by certain very interesting features.

In the first place, the autopsy showed that the chronic nephritis, although of uncertain origin, was of ancient date. The kidneys were granular and atrophied. The heart was of the type characteristic of chronic granular nephritis. It was enormously enlarged, and weighed 650 g.; there was no valvular lesion, but the wall of the left ventricle was very much hypertrophied, its thickness being over 4 cm. There was hypertrophy of the suprarenals, each of which weighed 17 g.

Under conditions such as these, the appearance of the terminal pericarditis is not to be wondered at. It developed, in accordance with the law laid down by MM. Widal and Weill, at the moment when azotæmia was at its height.

Three important clinical factors in connection with the case deserve closer consideration. They are: the X-ray examination, the seat and the characteristics of the pericardial effusion, and the epigastric method of puncture.

X-ray examination is practically essential to the formation of a diagnosis in pericardial effusion. As carried out in this instance by M. Gauducheau, it yielded results of very precise diagnostic value.

The area of the cardio-pericardial shadow was considerably enlarged. It was bulbous in shape, the superior portion narrowing into a thin pedicle of irregular outline. The right edge of the shadow was convex, the left was nearly horizontal and, along a large proportion of its length, it touched the external edge of the thoracic wall. The most interesting thing about the shadow, however, was its immobility, pulsation of its edges being nowhere perceptible. This combination of characteristics corresponds to the type first formulated by MM. Vaquez and Bordet (1). It is absolutely specific, and is certain evidence of large effusion in the pericardial region.

In the present case there was yet another feature of interest. The amelioration brought about by the puncture was so marked that I was able to submit

* A communication to the French Academy of Medicine, January 11th, 1916.

the patient to a second radioscopic examination seven hours after the first. The modification in the cardio-pericardial image after the withdrawal of 1,100 c.cm. of fluid—an enormous volume—was very striking. While remaining typically the same, the image showed two well-marked modifications: the right edge of the shadow was less swollen and was more nearly vertical; the left edge was separated from the thoracic wall, and the apex of the heart was visible. More important still, the cardiac contractions were clearly perceptible. But the area covered by the cardiac shadow was still abnormally large, pointing to considerable enlargement of the heart. This was confirmed by *post-mortem* examination, which revealed hypertrophy of the left ventricle in a heart weighing 650 g.

Unless skiagrams had been taken, I should have hesitated to affirm the presence of considerable effusion; still more should I have hesitated to puncture it. Auscultation invariably showed a continued and very intense friction over the whole of the precordial region. It was superficial and in no sense dulled, and suggested extensive dry pericarditis. Yet the serous sac contained at that time more than a litre of fluid. This point is one of exceptional interest, and suggests that pericarditis with friction may very frequently be accompanied by effusion. It is evident, then, that a diagnosis based on the assumption that the presence of friction precludes the presence of liquid would be liable to grave chances of error.

Without the aid of skiagrams, puncture would have been neither practicable nor permissible. Its performance was further justified by the employment of the new epigastric method introduced by M. Marfan, to which I shall return later. To puncture from the front, with a friction area which included the entire surface of the heart, would have seemed much too risky an undertaking.

In addition to its exceptional intensity, the pericardial friction in this case was characterised by certain very remarkable features. It was not only precordial, it was also axillary and dorsal.

It has always been said that pericardial friction-sounds are not transmitted; that, in the well-known phrase of Jaccoud, they are confined to the area of inception. But it is evident that this is not invariably the case, and dorsal friction-sounds must to-day be included in the symptom-complex of pericarditis.

The cases of dorsal pericardial friction which have up to now been described in France do not, I believe, number more than eight. Almost all have been observed in the province of Lyons, and are included in two papers by MM. Devic and J. de Teyssier (2) and M. Pauly (3) respectively. These authors give a more or less detailed description of the posterior pericardial friction in all their cases, and it is noticeable that the same descriptive phrase is almost invariably employed—namely, that the friction-sounds may be heard “even dorsally.” In a case given by Devic and Teyssier the description is a little more detailed. They say: “The friction-sounds were audible over the left side of the thorax and on the left side at the back. The dorsal sounds seemed more intense than those in the thorax.”

In the case of the patient L., this sign was of the clearest possible description. I observed it for the first time on the day after the withdrawal of the 1,100 c.cm. of fluid. Was it there before, and had I failed to perceive it? This is possible, for a student has since told me that he had noticed it from the time of the patient's admission. Yet, more than once, I ausculted dorsally in order to discover the possible existence of pleural or pseudo-pleural symptoms. These were absent, and I did

not observe any signs of dorsal friction until after the first puncture. Then they were unmistakable and typical in character. The friction was see-saw in character; it was persistent when respiration was suspended; it possessed absolutely the same characteristics as the frontal friction, but was less intense. Its zone was readily defined. Vertically, it reached from the third to the eighth vertebra; transversely, it extended beyond the median line and was continued, though rather more attenuated, to about 15 cm. to the right of the ridge of the spine. This transverse band of friction extended beyond the axillary line and became merged in the area of precordial friction. There was thus a kind of half-belt of typical pericardial friction-sounds which extended from beyond the right edge of the sternum in front and terminated on the right of the ridge of the spine at the back.

The friction over this area was perceptible from the first moment of its discovery until the end. At the time when the second puncture was performed, there was friction over the entire pericardium, both back and front.

What is the clinical significance of this abnormal area of friction, of which the present instance is the most perfect which has up to now been described?

First of all, let us consider the extremely variable results yielded by left dorsal auscultation in pericarditis. With the exception of a slight roughness in respiration at the base of the left lung there are, in the majority of cases, no abnormal signs. It is certain that at the level of the heart friction similar to that in front is present at the back, but it is not perceptible by auscultation. The friction is deep-seated, and the sounds are deadened by a thick layer of supple and aerated pulmonary tissue. In other cases, the signs observed are provoked by a co-existent left pleuritic effusion. Where no pleurisy is present, pseudo-pleuritic signs are sometimes observed. This constitutes Pins' syndrome, and seems to point to considerable compression of the inferior left lobe. There are, finally, those somewhat rare cases in which dorsal friction becomes apparent upon suspension of respiration. (It is well to point out here that no diagnosis of pleural sounds is possible unless the patient is made to hold his breath.) These cases, which include that of the patient L., correspond to marked compression of the left lung occurring under conditions which may be defined as follows:—

In all the descriptions of cases of this class which have been published one fact stands out very clearly. In every instance except one, cited by Bouillaud, there was a close resemblance between the symptoms and those of the pericarditis of Bright's disease. In Bouillaud's case there was valvular lesion of rheumatic origin, with a hypertrophied heart weighing 652 g. Cardiac hypertrophy is the rule in Bright's disease, the heart weighing as much as 450, 550, 580, or even, as in the case of the patient L., 650 g.

Dorsal pericardial friction, the outcome of an enormously enlarged renal heart, appears to be almost specific in the terminal pericarditis of Bright's disease. I am of the opinion—and my conclusions coincide with those of Dr. Pauly—that the friction-sounds are not transmitted from the front to the back. It is not the precordial friction which is heard in the back, but a friction between the posterior surface of the heart and the posterior parietal layer of the serous membrane. This may be regarded as the distinctive characteristic of posterior pericarditis, the frequency and the clinical significance of which have been shown in a recent monograph by M. Cassaët (4). In the case of the patient L., the *post-mortem* showed the lesions typical of extensive diffuse pericarditis, together

with a fibrinous exudation of the bread-and-butter character almost equally distributed over the entire surface of the heart.

According to M. Pauly, the presence of large pericardial effusion in itself facilitates the detection of posterior friction; the base of the left lung becomes collapsed, and the pericardial sac, enormously distended by fluid, comes into contact with the posterior thoracic wall.

The autopsy showed that all these anatomical conditions were present in the case of the patient L. There was considerable effusion in the pericardium; there was compression of the left lung, which was flattened against the thoracic wall and hollowed into a kind of deep cell with thin walls of pulmonary substance, into which the enormous mass of the heart and its envelopes was fitted.

Such is the pathology of these rare cases of posterior pericardial friction. It must be borne in mind, however, that the area over which the sounds are perceptible does not entirely correspond with the projection of the pericardium against the dorsal wall. To a certain extent the friction sounds are transmitted, and of this I was able to obtain proof. Between the first and second puncture I was able, by means of skiagrams, to define the superior edge of the pericardial contour and to trace its position upon the patient's skin. It was obvious from the position of these that friction sounds were perceptible well above the area of contact between the pericardium and the thoracic wall.

It is evident, then, that pericardial friction-sounds are not confined to the friction area; they are transmitted in a greater or less degree according to the prevailing anatomical conditions. A collapsed and flattened left lung must necessarily favour the transmission of the morbid sounds.

The method of pericardial puncture which I employed in the case of the patient L. possesses technical advantages which are of no small therapeutic significance. To puncture a pericardium is always an anxious business. In the first place, the indications for such a procedure are very rare; in the second the close proximity of the heart is bound to give rise to a certain measure of apprehension. By the introduction of the epigastric method, M. Marfan (5) has rendered an invaluable service to the medical profession. It is now possible by a perfectly safe and comparatively easy method to tap the effusion at the point where it accumulates in the most dependent portion of the serous membrane. I had never seen Marfan's puncture performed, yet I was able twice to puncture the pericardium, in the certain knowledge that I should penetrate neither the internal mammary artery nor the pleura, and with every chance of escaping the cardiac wall.

The *technique* of the method is of the simplest description. The patient is placed in a semi-sitting posture and supported by cushions. The site of puncture is on the median line below the apex of the ensiform cartilage, which serves as guide. The trocar is inserted from below and directed upwards, following the posterior face of the ensiform cartilage and sternum so closely as almost to touch it. The distance from the surface to the pericardium is, in adults, about 6 cm. As the liquid is evacuated, the patient is slowly raised, in such a manner as to allow the fluid to collect in front and below at the level of the point of the trocar. It is advisable that the puncture should be preceded by subcutaneous injection of spartein or camphorated oil. This is a precaution which I invariably adopt before puncturing a thorax.

In my judgment, Marfan's epigastric puncture marks a distinct advance in *technique*, and I do not doubt that the method is destined to supersede

all others. Owing to the toxæmia by which it is accompanied, a temporary relief, such as that afforded the patient L., is the best that can be hoped for in the pericarditis of Bright's disease. In other pericardial effusions, where the general condition is less grave, the method would undoubtedly prove of great therapeutic efficacy.

ORIGINAL PAPERS.

SOME OBSERVATIONS UPON THE ENDOCRINIC GLANDS.

By IVO GEIKIE COBB, M.D., M.R.C.S.,
L.R.C.P.,

Late Assistant to Out-patient Physician, the Middlesex Hospital, etc.

THE place which those glands possessing internal secretions now occupy in the practice of medicine cannot be over-estimated. Although it is only in recent years that their importance has been understood, every day brings to our knowledge fresh evidence of their vital influences upon the general bodily and mental health. When it was discovered that exophthalmic goitre owed its existence to an over-action, associated with hyper-secretion, of the thyroid gland, the first milestone had been passed in the path which led us to the discovery of the important part which the hormones play in our lives.

What we may call the grosser lesions due to disturbances in the normal ratio between the various internal secretory glands, are nowadays matters of almost popular knowledge. What we desire to emphasise in this article are the smaller signs and symptoms which, to the eye trained to observe, show minor disturbances, either of one or more glands, or of the balance between these glands. Many of these details, trifling in themselves, have been proved to be sufficiently characteristic to justify medical science in including them among the constant features which owe their origin to the ductless glands. When the pioneer work was being done on this subject, the evidences of the slighter disturbances of the endocrinic glands were regarded by many observers as too fanciful to merit serious consideration. Thus, when Levi and Rothschild first pointed to the "eyebrow" sign as indicative of deficient thyroidism, it was hard for many students of these matters to convince themselves that this sign was of any value whatsoever.

Nevertheless, this and other manifestations of equally slight nature are now admitted to be of the greatest value in diagnosing deficient thyroid secretion. Many of the signs of kindred nature are so slender as to require the most minute study and the most careful observation before we can say, with any degree of probability, which particular gland is at fault. The importance of this lies in the fact that many cases of "functional disturbances," which we have been content previously to cosset with various preparations, and to class as neurotic or neurasthenic, according to the depths of our

ignorance, are now plainly due to abnormal functioning of the endocrinic glands. This much is now generally known and universally admitted. Only relatively few observers recognise that this is not the *fons et origo mali*, but only one stage on the journey.

To take a concrete instance, let us suppose that a patient exhibits signs that the thyroid is not functioning adequately. The patient exhibits many of the well-known signs pointing to this deficiency. Most of us are well content to leave it at that, and even to spend time (which should be occupied in delving still further and asking ourselves why such a deficiency is present), on self-adulation at our extraordinary deductive powers. It is certainly true that we can benefit our patients by the exhibition of one or other of the organo-therapeutic products, but we shall do so to a much larger extent if we realise one or two simple facts.

When advising a patient to take, let us say, thyroid extract for a time, we are constantly asked by the patient the *rationale* of such a prescription. Having explained that we have reason to believe that this gland is not supplying an adequate amount of secretion, on more than one occasion we have been asked by the logical patient, "Have I got to continue this medicine for the rest of my life?" or "Will the need for its administration be overcome in due time?" This is an important matter, because it makes us think for ourselves, and not blindly prescribe drugs for indefinite times without reasoning as to their method and length of administration.

I think that we are justified in considering for a few moments what underlies the deficiency in secretion. It is highly improbable that one or other of the endocrinic glands would suddenly and without any stimulus refrain from supplying, or determine to over-supply, its valuable contents to the blood-stream. It is much more probable that some cause, be it mental or bodily, has determined this upset, and it behoves us to realise that this is the case, and not to consider our diagnosis completed when we have made up our mind that such and such a gland is defective or over-active.

In his book on "Intestinal Stasis," Lane states that one of the effects of intestinal intoxication is atrophy of the thyroid. Here we have a definite attempt to go to the root of the trouble, although unfortunately there is little evidence at present for this statement. For the present, at any rate, therefore, let us assume that this is one of the causes which underlies sub-myxoedema. What others may there possibly be? Among the causes of diabetes which find their place in most current textbooks on medicine is worry and anxiety. Now, this is at once assuming that mental causes may upset a bodily function or functions, and thereby disorganise metabolism. And the writer of this article would be the last to wish to deny this. If, therefore, we may assent to this detail of aetiology with regard to diabetes, why should we not include such a cause when we are discussing disorganisation of the endocrinic glands? Many cases which we can call to mind at the moment afford us the strongest possible support for such a theory. Prolonged anxiety, business worry, a sudden shock, are said to be capable of producing diabetes, just as puncture of the floor of the fourth ventricle is, experimentally, capable of doing the same. It would seem at least equally probable that the same causes can, and do, upset the mechanism which governs the balance between the ductless glands.

In the severe cases of this nature (*e.g.*, Graves' disease), this fact is sufficiently recognised. But is it—has it been—when we come to consider slighter derangements of these important glands? It is obvious that the entire study of this subject is

of too recent a date to have made the minute clinical study of the ultimate cause a feasible proposition. Nevertheless, we now come to the time when our patients ask us the why and the wherefore of such prescribing.

We have suggested two possible causes which may underlie the disorganisation of the endocrinic system—namely, intestinal toxæmia (as suggested by Lane), and mental causes, such as worry, anxiety, and mental strain of any kind. But are these the sole causes which may be held responsible? We are all familiar with the damaged health which may result from a long illness, or, alternatively, from a sudden short attack, such as influenza. The patient recovers but slowly, the strength returns not, the mind is clouded, and in countless other ways the individual shows the effects of the illness. Hitherto, we have referred to such cases as post-influenzal debility, when this disease has been at the root of the trouble, or as "neurasthenia" when we could not find a cause, even as tangible as influenza. Our remedies have been confined, certainly in many instances, to a change to the sea or spa, and a generous addition to the diet. But we have rarely asked ourselves what factor underlies these "delayed recoveries."

Why should not the toxins of influenza, in like manner to the toxins generated by the inhabitants of the bowel, or the adverse mental influences which exert their harmful action where mental strain is present, be capable of producing an endocrinic disorganisation? Hypothetically, at any rate, such an occurrence is at least probable; and it would give us a reason for the sudden or gradual withdrawal of the internal secretion which happens to be deficient in the particular case.

From the practical standpoint, moreover, we must advance some such hypothesis as this, in order to account for the train of symptoms, which, certainly in many cases, owes its origin to a disturbance of the normal ratio which exists in health between the various endocrinic glands. Again, most of us are familiar with the cases of delayed convalescence following an operation. The patient invariably presents a similar picture to that designated "post-influenzal debility." In theory, at any rate, he ought to respond to the administration of one or other of the preparations of the hormones, and in many cases he does.

On more than one occasion I have had the opportunity of putting this theory into practice. One lady consulted me some years ago for neurasthenia following a severe abdominal operation. This condition had resisted a wealth of treatment; many and diverse remedies had been tried without relief. I hoped that I might be enabled to afford relief by the administration of an organo-therapeutic preparation. On considering her syndrome, I came to the conclusion that she might derive benefit from the exhibition of pituitary extract. In spite of the laboratory evidence which should convince us that it is useless to give an extract of this gland by the mouth, I took my courage in both hands and prescribed it. The result surpassed even my optimistic expectations. The lady recovered her strength and health; her digestion righted itself; her functions became normal, and she regained perfect health. This result is striking, for it followed many other remedies, and the patient herself always refers to this medicine as the "magic mixture."

I mention this case, as it exemplifies our hypothesis that many and diverse causes may produce a change in the normal functioning of these glands. Whether, in this particular case, it was the shock of the operation, the anæsthetic, or the changes in diet necessitated by these procedures, it is impossible to say. Another example of a similar attack

of "thyroid deficiency" is the case of a lady who, having nursed her husband through a long and trying illness, which resulted fatally, consulted me for symptoms which, upon investigation, were shown to be due to deficient thyroid secretion. Upon the administration of thyroid extract, she made a capital recovery and was restored to health.

These cases both help us to answer the question so often put to us when we recommend an extract of one or other of the ductless glands. It would seem that, certainly in many instances, the administration of the extract either by the mouth or hypodermically, serves to act as a stimulus to the normal secretion, so that it is unnecessary to continue artificially its administration for lengthy periods. But, again, the prescribing of the requisite extract at the right time is the "shortest cut" to health which exists.

It is even possible that many of the benefits which we all recognise to accrue from a change of climate, from a course of spa treatment, or from a sea voyage, are really largely efficacious because they stimulate into activity the gland (or glands) which has been temporarily inhibited by the illness, operation, or other cause. In this connection, we may refer to another instance where "post-influenzal debility" has yielded to organo-therapy. A lady consulted with me for this condition, which had been in existence for five years, and which had resisted all treatment. It had commenced after a bad attack of influenza, five years before. Her condition was much improved from the first by the administration of thyroid extract, and she made a most satisfactory recovery.

The point which seems to need emphasising is this: that prolonged illness, shock, mental anxiety, and many other causes produce effects which owe their origin to a disturbance of the relation between the hormones. The indications are rarely broad; Sometimes they require the eye of a medical "detective" before their significance is realised. But signs and symptoms are rarely wanting if they are looked for.

Neurasthenia has been likened to influenza (inasmuch as any intangible condition has received this label), and has been dubbed the "dustbin of the neurologist." Nevertheless, it is a real and concrete disease—concrete in the sense that it is not a hotch-potch of other diseases. Doubtless some of the diagnoses which have been made under this name, would in reality have received another title did we but realise what was the underlying pathology. Some patients who have been called neurasthenics, are in reality neurasthenics, but they are neurasthenics because they are suffering from a deficiency of hormones.

I may perhaps be allowed to mention one other case, as illustrating the relation between neurasthenia and the endocrine glands. During the course of last year I was consulted by a doctor, who informed me that he was a neurasthenic, and brought me a type-written account of his symptoms in support of this statement. I need not describe the case in detail, as the few points I mention will serve our purpose.

The patient complained that he was slow mentally, became extremely tired after comparatively small exertion, was exhausted after sexual connection, unable to concentrate for any length of time, and so on. On examination, I discovered a very slow pulse (barely 50 to the minute), a dry and rough skin, prematurely grey hair, especially over the temples (the patient was in the thirties), trophic changes in the skin appendages, and many other minor signs, which I will not waste time by enumerating. Suffice it to say, that the patient presented a typical picture of sub-myxedema, and

I advised small doses of thyroid. Some months later he advised me that he had suffered from some "extraordinary sinking feelings" when he had taken the thyroid, and in consequence had been forced to abandon it. I explained that these were most certainly due to the stimulating effect which the thyroid would produce upon the circulation, and I encouraged him to persevere with it. The interest of this case lies in the fact that all the symptoms had gradually supervened after an attack of influenza, and that their real nature had never been diagnosed.

Such a case as this will serve to show how a certain proportion of patients who have been treated, and only too frequently dismissed as incurable under some such name as neurasthenia, may be helped by the judicious administration of these extracts.

I need not offer an account of the symptoms which make up these diseases, nor is there need for me to describe in detail what is so well known about individual symptoms of deficiency in thyroid, in pituitary, or in adrenals. But one or two points have come to my notice about these conditions that I should like to mention in passing.

There can be little doubt that deficiency in thyroid secretion comes on more or less suddenly in some cases. I recall the case of a young male subject, who developed this complaint after a hazardous season on the Stock Exchange. His condition, when he came under my observation, was typical, and he made speedy progress under thyroid medication. Again, I have seen a typical attack of sub-myxedema develop after one of the exanthemata; likewise excessive thyroid secretion ensue after such a disease as rheumatism. The treatment of this latter condition resolves itself into the administration of extract of the pituitary or adrenal gland, combined with other remedies which tend to counteract the excessive secretion, such as rest, calcium salts, glycerophosphates, etc.

It may be of interest to note at this place the extraordinary intolerance to tobacco which develops when the thyroid secretion is deficient. I have, on several occasions, observed that the patient, a heavy smoker previously, has had to abandon the fragrant weed, at or about the time when he commenced his illness. I have been told that even one cigarette is followed by unpleasant sensations; and I have ascertained that blood-pressure has been lowered as much as ten points after one cigarette.

These occurrences all point to the fact that, given suitable conditions, it is not a difficult matter to upset the normal ratio between the various hormones. It is necessary in these cases to study the antecedent conditions with as much care as we should when taking the previous history of, let us say, a case of tuberculosis. For in these patients we can often discover some occurrence which may well have some bearing upon the ætiology, and may give us valuable information both as to the actual cause, and as to the particular gland at fault.

Unfortunately, the therapeutics of the other glands are scarcely in such a satisfactory state as that of the thyroid gland; and we do not, in practice, obtain results as striking as those which so often ensue from the administration of thyroid. But, before leaving the subject, we may say a few words as to the prescribing of the adrenals.

The extract of the adrenals may be given in the form of dry extract, and it is often of great benefit to those patients who are weakly, debilitated, with a low blood-pressure, and constant fatigue. These are the cases of neurasthenia in which this extract should be tried. Again, the preparations of one or other part of the pituitary gland are in some of these cases more beneficial; while it is sometimes of

service to use what Leonard Williams calls a "mitrailluse"—*i.e.*, a preparation containing the extracts of many glands. Such a one is Hormotone, and it is claimed that its exhibition is followed by marked benefit in many indefinite conditions.

The method of treating disease by means of extracts of the endocrinic glands is, relatively, still in its infancy, so we must not be hypercritical at that part of this medication, which works without the support of the laboratory. But, as has been admitted elsewhere by a physiological chemist, clinical experience often is at variance with laboratory results, and clinical results are not always in the wrong. However much we may condemn the indiscriminate and speculative use of these extracts without adequate reasoning, if we abide by laboratory results, and never test these by practical endeavour, we are liable to remain with little added knowledge on these subjects as the years roll on.

The practitioner must perforce use his eyes before he prescribes thyroid extract; he must be familiar with the small signs which go to make up the picture of deficient or excessive action of this gland; but he must not hesitate to prescribe this substance, although the signs are slight. But if he must be familiar with the diagnostic features, he must be equally *au fait* with what is now known as to rational treatment. He must choose a carefully standardised preparation, he must be careful that his preparation is new and not several months older than when the local chemist purchased it from the wholesale house; and, finally, he must understand that the dose is a matter deserving the closest attention. Thyroid, to quote one example, is not a drug to use from three to ten grains, but in fractions of a grain, certainly to commence with. Had it not been for the fact that it has been utilised to reduce weight, the probability is that it would not have obtained that popularity which it now possesses in the lay mind. This has made its administration a matter of danger, especially when we consider that the dose, or rather the initial dose, is often far too large.

Convalescence is often accompanied by deficiency in the thyroid gland, and its administration in minimal doses is of very real help. During the months which follow a serious illness, such as pneumonia, the administration of a "mitrailluse" is frequently indicated.

To all those who treat neurasthenia, who have to lighten the lot of those unfortunate sufferers from what are known as "the functional neuroses," the importance of organo-therapy cannot well be over-estimated. When administered with intelligence, with the patient under observation, there need be no risk in such prescribing. Rather is there a risk in prolonging a morbid condition owing to neglect in the faculty of observation or an oversight as to the underlying causation.

Again, what a difficult matter it is to "fatten up" some patients. Rest-cures, hyperalimentation, malt extracts, digestive ferments—all seem to be of no avail. But the extracts of the ductless glands will often be found of service, when taken with regularity. It should, however, be remembered that thyroid must be prescribed with great care in such cases as these. Extracts of the brain and spinal cord, of the pancreas and liver, of the testes and seminal vesicles, are of much help. I have recently had under my care a man suffering from advanced neurasthenia, whose weight had dropped from eleven stone to between eight and nine. Under the administration of a mixed extract his weight is now (one month after the commencement of treatment) nearly ten and a half stone, although nothing had previously been able to stop the loss of weight.

In the *Practitioner* for January and February,

1915, will be found many able articles from the pens of experts on the subjects of the endocrinic glands. These articles discuss fully the available material both from the standpoint of the laboratory and the bedside. A perusal of these numbers will well repay the time occupied.

It is hoped that this article will succeed in pointing out some of the ways in which the hormones may be utilised, and a few of the morbid conditions in which they are indicated. That a great future lies in front of this method of treatment no one will doubt. But we may also express the hope, in conclusion, that the reason why changes in the normal relation of the hormones take place will be investigated fully, as well as the changes themselves. When we have more information as to the occasions on which we may expect this important system to be upset, then shall we have more definite information for our therapy.

A NOTE ON THE DISTRIBUTION OF CASES OF CEREBRO-SPINAL FEVER IN A MILITARY CAMP.*

By GEORGE E. NESBITT, M.D.DUBL.,
F.R.C.P.I., D.P.H.,

Assistant Physician to the House of Industry Hospitals,
Dublin.

In a paper read before this Section in April, 1915 (*MEDICAL PRESS AND CIRCULAR*, May 19th, 1915), I drew attention to the difficulty in tracing the source of infection and the mode of spread of cerebro-spinal fever. With reference to an outbreak in the Dublin district in that year I remarked: "No connection whatever could be traced between any of these cases, no two of which happened in the same room, or even in the same block of buildings. The disease seemed to exhibit a curious perversity in emphasising this point."

Following the usual course, however, the epidemic died out towards last summer, and during the autumn and winter no cases were reported. In January of this year the disease reappeared in a large military camp. The first case occurred in a brick-built barracks at a considerable distance from the remaining cases who occupied huts erected last year. It was, apparently, a so-called sporadic case, and, except as a coincidence, had almost certainly no connection with the small epidemic which followed.

Though this epidemic numbers only nine cases, it exhibits certain features of interest, more particularly with reference to their curious distribution.

A plan of the camp shows that it consists of three separate divisions, two being adjacent, the other 600 yards distant, open grass land intervening. The shortest distance between the huts is 30 feet. The huts are designed to accommodate twenty-eight and thirty men, but the full number was seldom reached. There was no overcrowding, though the entire camp was occupied by about three thousand men. As a matter of fact, the only drawback to perfectly hygienic conditions was the sodden state of the ground surrounding the huts, due to the exceptionally heavy rainfall during the winter. I incline to the belief that this factor is important.

I have indicated on a diagram [not reproduced] the position of the huts where the cases occurred, numbered according to date of appearance. It should be noted that no two cases occupied the same or even adjacent huts, that the order of appearance is quite irregular, and that the cases are widely spread throughout the camp.

The first case developed on January 22nd in a

* Read before the Section of State Medicine in the Royal Academy of Medicine in Ireland on Friday, April 14th, 1916.

hut marked (1). Next day the second appeared two huts off. The third ten days' later in the distant section of the camp—i.e., six hundred yards off. No. 4 next day jumped as far as possible in the opposite direction, followed by (5), eight days later, two huts distant. Two days after No. (6) appeared—back in the distant camp, but not near No. 3's hut. Then in five days No. (7) as far as possible from any of its immediate predecessors. Nos. (8) and (9) did not appear for a month after—a week and six or seven hundred yards between the two.

So far as could be ascertained these men were not in direct contact—in fact, they were unknown to each other previous to admission to hospital.

A careful examination of these data suggests that direct infection plays a very small part in the spread of the disease. Popular opinion would, in this respect, appear to be at fault. Proved cases are rather rare in the literature of the subject, and my own experience includes only one fairly certain example—a hospital resident.

Amongst the numerous suggested possibilities I would place the climatic factor first. Exactly how it operates is a matter for further investigation.

I must express my hearty thanks to Lieut. R. H. Cox, R.A.M.C., who has medical care of these troops, for much assistance in the investigation of the outbreak and for an excellent scale map from which my diagram is prepared.

The treatment in all cases was serum intrathetically, and of the nine four died.

CONCERNING RUBBER GLOVES.*

By ROBERT T. MORRIS, M.D.,

Professor of Surgery, New York Post-Graduate Medical School.

SOME years ago I published an article condemning the indiscriminate use of rubber gloves. This brought out favourable comment from a number of the older expert surgeons, and it called up a great deal of unfavourable criticism from men who had been trained to believe that rubber gloves should be employed in all operative surgical work. Perhaps it is now time for me to state clearly certain views which are the outcome of more extensive experience.

First, let us take up the matter of principles. According to the fundamental ideas of the third or pathological era of surgery, the operator was to remove bacteria and their products most thoroughly from any infected area. This called for a degree of technical work which represented progress, but nevertheless often proved injurious to the patient. Furthermore, it was frequently unnecessary. We are now passing into the fourth or physiological era of surgery.

The main idea about which our new methods are grouped consists in giving the patient the mildest attack of surgery which will suffice for turning the tide of battle between bacterium and organic cell. It is the idea of conserving the patient's energies and turning him over to himself as expeditiously as possible—in other words, giving him "home rule." Most surgeons cannot introduce their nicest manual *technique* when wearing gloves.

The methods of the fourth era of surgery include the idea of the least possible degree of handling of sentient tissues, and the shortest incisions which will suffice for accomplishing an object without jeopardising any of the patient's interests. Furthermore, rapid work is desirable in order to avoid sending prolonged destructive influence into the patient's centres of consciousness, which are never wholly asleep, no matter what

degree of anæsthesia may be employed. Regarding this, Dr. T. L. Bennett says that the best surgeon is the one who acts all of the while as though he were afraid of waking the patient up.

In order to follow the principles of this fourth era of surgery, one needs to depend very largely upon the sense of touch. We have often to work by touch in a class of cases in which a phrase "expose all of the pathology" belongs to the third or pathological era of surgery, now passing. It is better not to expose all of the patient's pathology in many of these cases in which we already know what that pathology is, and what the patient will be able to do with his repair machinery if he is not shocked too deeply.

In some cases a large incision and tedious technical ideal work will allow more bacteria to fall into a wound from the air than would be carried in by well-prepared surgical hands.

This matter of careful preparation of surgical hands is sometimes neglected by men who put too much confidence in their rubber gloves. I would not advocate any idea which jeopardised the patient's interests. On this basis I made at one time a quiet examination of hospital records of a number of surgeons who worked without gloves, and of a number who worked with gloves. Some of us who depend upon careful preparation of our hands had fewer cases of infection than were recorded against other operators who used rubber gloves in all of their operative work. In only one instance did a surgeon who wears rubber gloves continuously have better results than my own, and he is a better surgeon than I am, anyway.

For hand preparation I have depended for some years upon one of the chemical substances which does not coagulate albumin, and which leaves the skin of the hands soft, and free from that epithelial injury which follows the use of bichloride of mercury. There is doubtless a difference between hands of various surgeons in this respect. Hands which are continually moist, indicating some chronic toxic influence (chiefly from the colon, according to Lane) may carry more active colonies of latent bacteria in their epithelium than would be found in the epithelium of the hands of men in perfect health. We have laid too much stress upon the need for the employment of germicides in hand preparation, when a powerful antiseptic, not a germicide, might cause less injury to the protoplasm of the epithelium of the surgeon's hands.

The advantages of working by the sense of touch in preference to the sense of sight in certain cases has been recognised by surgeons since the earliest days of surgical history. The sense of touch is dulled by the best of gloves.

The operator in a case of perforated ulcer of the stomach, working by sense of touch, may introduce drains down to the region of perforation and complete his preliminary operation in three or four minutes of time, leaving subsequent details for a secondary operation.

In typhoid perforation, or in cases for drainage of the fluid belonging to parenteral anaerobes in typhoid hemorrhage, the entire operation from first incision to last suture may sometimes be done in seconds instead of minutes where one is working by the sense of touch.

When removing firmly adherent organs like oviducts in cases of pyosalpinx, or the appendix in acute infective cases, work may be done through short incisions by aid of the sense of touch very rapidly and accurately. Long incisions naturally predispose to the development of post-operative hernia, if the patient has the luck to live and face that danger.

For cases in which we need to be particular about

* *New York Medical Record*, March 4th, 1916.

scarring, one will often work to advantage through incisions which could not be employed if the sense of sight were our chief dependence.

On the other hand, rubber gloves may be worn to advantage in almost all of the so-called "external operations," such as amputations or excisions, or hernia, in fact I need not enumerate. Surgeons there be who are not well trained in the principles of asepsis or of antisepsis, yet who are doing a great deal of operating. For such operators I would prescribe the employment of rubber gloves under all circumstances.

The question of wearing rubber gloves was first brought forth actively at a time when I was most deeply engaged in forwarding the principles of the fourth era of surgery, and for that reason my stand against the indiscriminate use of gloves may have been made with more emphasis than would be placed upon the subject at the present time, when very thin flexible gloves are to be obtained from the manufacturers. Rubber gloves which were put upon the market at first were comparatively thick and cumbersome.

Excepting in abdominal work rubber gloves give a certain percentage of results in their favour, even with the most expert operators, provided that very thin gloves are used. Personally I prefer the ones which are made in such a way that the knuckles of the operator are left free, without the necessity for putting the rubber particularly upon the stretch over the knuckles. There is thus less interference with the sense of touch under these circumstances.

There is no need for bringing up the question of desirability of rubber gloves for use in obstetric work or in various examinations, or for protection of the surgeon in some fields of work in which the advantages are obvious.

Improvements in rubber gloves have been so marked that I do not now have the feeling that was engendered when I saw dangerously bungling work done by men who were wearing thick gloves. At that time it was evident that younger men who were being trained to wear gloves in all operative work would never develop the fine sense of touch belonging to the surgeons of a past school.

DOPE POISONING.

By F. BARLOW, L.R.C.S.E., L.R.C.P.E.,
L.R.F.P.S.GLAS.

THE term Dope Poisoning is given to a definite train of symptoms affecting those engaged continuously in the final manipulations on the canvas of aeroplane wings. In the early days before the nature of the agent, active in the production of this disorder, was appreciated, hoppers were erected above the part being doped. At present the rational method of ground-suction ventilation is proving much more efficacious, since this mode of action is based upon considerations of the essential physical characteristics of the noxious agent to be dispersed. Undoubtedly in some of the cases seen, a certain part of the symptoms, especially in young girls, is of an hysterical-autosuggested type, probably induced by the constant dread of this affection and the fact that they see fellow-workers, with whom they are daily in close association, continually falling out owing to this complaint. A vicious circle is thus very soon established unless from the very outset the matter is dealt with in a firm and skilful manner by the medical officer in charge. Discrimination between these pseudo poisonings and the true cases of Dope intoxication, also the detection of those other cases in which there is a certain element of poisoning overshadowed by subjectively exaggerated sym-

ptoms, and to allot to each its true proportion in the special diagnosis of the case under consideration, may present great difficulty until the patient has been under observation for some time.

As a rule, the first complaint by a patient, that would direct suspicion of the case being one of Dope Poisoning, is a persistent pain in the back. This is aggravated by exertion or standing, and but slightly relieved by rest. The pain is usually worse in the day, progressing in intensity throughout the working hours, until towards the evening these patients have to interrupt their work at frequent intervals to rest. On examining the painful area of the back, it is found to coincide roughly with Morris' quadrilateral. There is no pain on light palpation, but deep pressure or dipping the fingers produces sharp lancing pain. Examination of the abdomen and pressure in the hypochondriac and epigastric region generally shows nothing abnormal. Coincident with the onset of this pain in the back observant patients will state that they noticed the urine assume a darker hue progressing to a deep orange shade. If a specimen is examined at this stage albumin will usually be detected, and in many cases the Hæmoglobin test (Guaïac and Ozonic Ether test) falls out positive.

Jaundice is also an early and progressing feature, but is, as a rule, of such gradual onset that it is the friends of the patient who first notice it.

Constipation, less noticed by women workers, probably because with them this state amounts in many instances almost to a physiological condition, is an early and troublesome feature. Additional symptoms which gain importance by their aggregation are: nausea or even vomiting, often complained of after the first few weeks of work, vague abdominal pain, vertigo, tachycardia, breathlessness and a general feeling of malaise. If these workers are transferred from Dope work at this stage and given employment which does not bring them into contact with any of the doping process or dope workers, all symptoms usually rapidly subside.

Almost all the dope workers say that their mouth or throat feel dry and sticky, and complain of a persistent taste which they compare to the smell of the dope. The mucous membrane of the buccal cavity and nose has a pale and dull appearance and the saliva and nasal secretion is of a greater consistency than normal.

Since there is no precedent to guide one in the treatment of Dope Poisoning, the following method seems at present to be the most satisfactory. Its object is alkaline saturation of the tissues. Many of the most alarming and troublesome symptoms have a marked resemblance to those met with in cases of acidosis. Whether this similarity is essential or fortuitous I cannot say, but it certainly is quite remarkable in some instances. The patient is put to bed between blankets and, since a feeling of chilliness is usually complained of, hot-water bottles are placed at the extremities. A dose of calomel combined with bicarbonate of soda is given, followed by a saline. An alkaline mixture of the following type is exhibited:—

R. Sod. Bic., oz. i.
Mag. Carb. Poud., dr. ii. gr. 40.
Bismuth Carb., dr. ii. gr. 40.
Tr. Bellad., dr. ss.
Tr. Nuc. Vom., dr. i. ss.
Paraff. liq., q.s.
Aq. chlorof. ad. oz. viii.
Sig. Oz. i. T. W. S.

Unless albuminuria is a marked symptom, a small dose of calomel is given daily for four or five days.

The diet consists of milk, milk and soda water, and any of the well-known malted foods (Benger's,

Allen and Hanbury, Horlick's Malted Milk, etc.), pure flavoured gelatine, but no meat jellies. The patient is encouraged to drink large quantities of water, preferably as hot as can be taken in sips. The water can be made palatable, so that large quantities can be taken, by a pinch of salt or a clove dropped in if hot, or a slice of lemon or orange if cold. Barley water freshly prepared, weak tea, or imperial drink can be added, but no coffee, cocoa or alcoholic beverages are allowed. Free daily evacuation of the bowels must be procured.

The patient is kept in bed until all the symptoms have subsided. Under this régime the patient usually recovers rapidly if the case is seen early enough.

The preventive measures that suggest themselves are:—

1. A thorough downward ventilation, especially active immediately below the place where the doping is done.

2. Roomy, but not necessarily lofty workshops.

3. Impermeable gloves to be worn by the workers during the time they are engaged in doping. The hands to be washed with spirituous or ethereal soap (special attention to scrubbing the nails) immediately after working with the dope.

4. Daily inspection of the hands of workers, especially before meals.

5. Prophylactic daily dose of some alkaline mixture.

6. Cessation of all dope work upon complaint of any characteristic symptom.

In conclusion, it is interesting to note that women workers appear to suffer more frequently and severely from this affection than men. Whether because there are a greater number of women employed in this manner than men, or because men are more resistant, is difficult to say. There is also a great difference in the susceptibility of individuals.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

SURGEONS AND PETROL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—“The medical advisers to the War Office have decided that London consultants can do without cars—or drive them themselves.”

Such is the edict of the various tribunals before whom these medical men appear who wish to obtain their chauffeurs' release. Let us now consider how this decision is arrived at and analyse its justice.

The medical advisers in this instance appear to be the Central Medical War Committee—or rather that small sub-committee responsible for the arrogance and ill-temper which met representatives of the medical profession some weeks ago. These men, chagrined at the failure of the consultants to accept them with open arms, have wreaked their petty vengeance in the above manner.

Consultants, they say, are not wanted! Now, let us concede that every eligible man should serve; that feeling and no less is representative of the thoughts of all medical men, consultants and general practitioners. But let us also in all fairness consider the question from the point of view of the surgeon. It is he who most needs a competent chauffeur. Some of us there are who can drive

even in the present Cimmerian gloom with unshaken nerves. More power to them. Other weaker mortals, like myself, cannot. Years ago, before the war, I learned to drive. Pleasant it was spinning along the clear roads. Soon an urgent case called me to a suburb, and on the way a hair's breadth escape shook my budding confidence. At the operation the knife quivered in an unpleasantly dangerous fashion.

A week later, having operated consecutively for five hours, returning home dead tired, I allowed my attention to wander, with the result that in the same journey I knocked over a cyclist and finished up in the back of a hansom. I then resigned the wheel in favour of my chauffeur.

That represents the surgeon's side of the picture.

Let us suppose that one of the great ones of the Army Council or the self-opinionated members of the British Medical Association are suddenly stricken with severe abdominal pain. A surgical crisis has arisen, and a surgeon is summoned. Perhaps he has no car and cannot get down—or perhaps he starts and gets a puncture on the way—or goes astray from the road to his destination. Hours late, with a shaking hand and disordered mind, he reaches his patient, and may have to perform a critical and urgent operation.

I can wish nothing worse for those unreasonable gentlemen that I have indicated than that such a fate may befall them or their families.

I am, Sir, yours truly,
“S. O. S.”

[We know at least two eminent surgeons who have never driven a motor car and who do not intend to learn to do so.—ED., M.P. and C.]

THE STUDY OF THE INTERNAL SECRETIONS

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The increasing appreciation of the importance of the glands of internal secretion and their influence upon the ætiology as well as the treatment of many disorders, has made the subject of unusual interest to many physicians. It has been suggested recently by several American physicians that it might be advantageous to form an “Association for the Study of the Internal Secretions;” and it is desired to know whether there is sufficient interest in this matter to warrant its further consideration.

A few of the prospective advantages of such an association would be: (1) the assembling of those with a mutual fellowship of interest in this subject; (2) facilitating the exchange of ideas, inquiries and reprints on the internal secretions; (3) enabling those who are interested, but do not have the facilities, to be kept in touch with the articles that are appearing on this subject so frequently, but in such scattered and inaccessible periodicals—perhaps a monthly list of these articles with a brief résumé of their contents eventually might be prepared; (4) facilitating concerted clinical study of various phases of the subject, and also the measures being brought forward in organotherapy.

No effort has yet been made to form such an association; but any physicians who are interested and would welcome the establishment of a community of interest embracing some or all of the points just mentioned, as well as others which cannot be enumerated for lack of space, are requested to send their names and addresses (on a postal card preferably) to the undersigned, at 715-19, Baker-Detwiler Buildings, Los Angeles, California, U.S.A.

HENRY R. HARROWER, M.D.

PANEL MEDICO-POLITICAL UNION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—May I be allowed to dispel the belief which you apparently hold as to the constitution of this Union? You conclude the "Peripheral" observations in the current issue by saying:—

"It is a pity that the Panel Medico-Political Union appears so to have restricted its scope as to exclude those who are not panel doctors. There are other members of the profession who might suitably be included within the fold of its activities."

If you will be good enough to refer to the Rules of this Union (a copy of which is enclosed), you will notice that any duly qualified medical practitioner within the meaning of Section 34 of the Medical Act, 1858, is eligible for membership. Every application, however, is considered by the Council, and no name is enrolled until a ballot in favour has been registered. Yet, while our constitution is framed so as to embrace the whole of the medical faculty, we have not, in practice, upheld the candidature of any member of the profession who is not engaged in panel practice. The reason for this attitude is, I believe, manifest to all who have followed the manner in which the Government has of recent years interested itself in medical matters.

I think it may be safely asserted that, with the introduction of the National Insurance Act, the pure individualism of practice, at least among the poorer classes of the community, disappeared. Those doctors who were responsible for the formation of this Union soon realised one important fact—namely, that it depended entirely on the practitioners themselves whether the change that had thus taken place, with so much parade and ostentation, was or was not to be to our advantage. For, in the place of private adjustment as between a doctor and his patients, we have, under the panel system, a contract between the State on the one hand, and a body of some 15,000 medical practitioners on the other. And the only way in which persons bound by contractual relations can adequately safeguard themselves is by availing themselves of the immunities provided by the Trade Union Acts.

The State does not, it is true, differentiate between the profession as a whole and that vast section which has taken service under the National Insurance Act: the Local Medical Committee is appointed by the doctors in a particular area and not exclusively by panel practitioners; and the regulations relating to the constitution of panel committees enjoin that at least three-quarters shall be panel practitioners. We, however, are convinced that panel matters should only be discussed by panel men, and that an independent organisation is an absolute essential.

The work undertaken by the Union, however, is not and cannot be restricted to the panel service alone. The panel doctor is not a panel practitioner only. He is also a general practitioner. Consequently the needs of general practitioners are also the needs of the panel profession; but the converse does not necessarily apply. It is for this reason the Union has advocated, and has so determined its administrative policy, that in panel matters, to achieve the best results for all concerned, the deliberative body, which it is the business of the medical faculty to provide, must be composed entirely of panel practitioners. This does not imply that extraneous advice shall not be obtained. It simply means that the ultimate decision shall rest exclusively with the interested parties. If, therefore, non-panel men are to be admitted into the Union, they must fully understand that they will have no vote in panel matters.

This Union was formed to resist encroachments upon the rights and privileges of the medical faculty, and to promote its interests in every legitimate way. We are not hostile to the British Medical Association. We apply fair criticism to its actions; and when we consider that it has taken a false step or made a colossal blunder we are not slow in passing strictures upon and severely censuring its conduct. We do not think it can be controverted that the Association is—owing, presumably, to conflicting interests and extraneous influences—completely unable to negotiate with the Government from a well-defined standpoint—hence the recent compromises which have proved to be so unfavourable to the bulk of the profession.

In conclusion, I should like to add that I share your views that the scant leisure of the general practitioner has been responsible for his apathy. To spend one's life tending the sick in an overcrowded industrial area should call forth expressions of thanks from a grateful Government; instead, we find no opportunity is lost to hem the profession in with regulations and, by imposing "un-feed" duties, to add to its burdens. This could never happen if the profession were properly organised and could make its voice heard. We owe you, Sir, a debt of gratitude for sounding such an eloquent call to arms.

I am, Sir, yours truly,

A. WELPLY,
General Secretary.

47, Fleet Street, London, E.C.
May 18th, 1916.

THE CONSCIENTIOUS OBJECTOR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Tennant, in the House of Commons, has expressed the wish that there was some formula by which these objectors could be brought to book. For those who object to serve on the ground that they are forbidden by the New Testament to shed blood on any grounds whatever there are plenty of formulas to hand, and I would advise all of this class of objectors to read and digest the Rev. Lawrence Green's letter which you published on the 10th inst. In that letter the religious qualms of the C.O. are, as far as I can see, absolutely settled, and the basis of Scriptural objection is completely cut away—an unpleasant fact perhaps for the objector, but one that has to be faced by him! I wonder how it comes about that so many conscientious objectors come from Cambridge, many more than from Oxford! I understand that the chapels at the Cambridge colleges are smaller than those at Oxford, and are not so well attended. Is there then something fundamentally different in the teaching at the two universities? Whatever may be the cause it is an interesting fact, and there must be some way of accounting for it. Dr. Gwillim Davies seems to be impatient with the law. Of course, the law is a changeable guardian—it must be so, because not only new perversions, but the misrepresentations of old obligations have to be dealt with as they arise, and the twists and turns of those who try to wriggle out of conditions which are inconvenient or unpalatable must be met by strong and new measures when, as is the case of the conscientious objectors, they threaten the safety of the realm. I suppose that if the C.O.s are sincere they would wish to see the whole nation made proselytes to their apostasy; where then should we be? The whole brotherhood of the C.O.s would be promptly exterminated by the conscientious Hun who would quickly impose a new "conscience" on any survivors, viz., that of doing what "Kultur" dictates!

Dr. Davies chooses Lavater's dictum from among those tendered by a "Student of Psychology." I thought he would—it seems to suit his purpose—but it is rather unfortunate because Lavater was an ingenious empiric, and not a scientific man. Personally, I prefer Montaigne, who says "the laws of conscience which we say are innate do really arise from custom," *i.e.* from environment, experience and education. If there is such a thing as a really conscientious objector he is of no use to the country, and in his isolation he is to some extent a menace to the integrity and solidity of the Empire. If he is not honest, but is the mistaken interpreter of true psychological terms, and refuses, in his self-esteem, to be properly instructed, why then he must be treated as any other dishonest person would be. There are, I know, many who try to obtain exemption from service for family reasons, many of which seem valid. These I think ought to be called simply "objectors"—they would fight if they could and they are entitled to consideration. They are of a different class from the objectors whose "conscience" is an artificial compound of self-interest and of special pleading. In conclusion I beg to thank you, Sir, for kindly opening your columns to a discussion on this burning subject.

I am, Sir, yours truly,
T. CLAYE SHAW.

Weymouth Street, London, W.,
May 19th, 1916.

PATENT MEDICINES AND THE BUDGET.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Who is it wants the patent medicine fraud done away with? Is it the health crank, the sanitary reformer, the medical profession, or any other party in the State? The man in the street, the voter whom the politician must conciliate if he would retain his salary, is quite cold about it. He argues that the doctor sells him a bottle worth twopence and charges him from eightpence to half-a-crown for it; and he is unable to see why, if it is morally right for the doctor to do so, it should be morally wrong for his rival, the quack, to sell him a penny box of pills for a shilling. I don't expect to see any more come of the Report of the Select Committee on Patent Medicines, nor any reform in the patent medicine system, until medical practitioners either cease to sell medicine, or where that is unavoidable, sell it at cost price. Alas! it is futile to expect a trader to voluntarily abandon 100 to 200 per cent. profit and no questions asked.

I am, Sir, yours truly,
M.D.

THE B.M.A. AND THE L.G.B.

138, Harley Street, W.,
May 15th, 1916.

MY DEAR HARMAN,—At our annual meeting I wish to ask a question: "Is it true that the deputation from the head office of the B.M.A. to the L.G.B. admitted that 1s. would be a sufficient fee for notification of infectious diseases?" If the answer is No, the matter drops; if the answer is Yes, then I move:—

"That the Marylebone Division expresses its indignant surprise that the B.M.A. should have made such a statement, and asks the representative meeting to express its disapproval and also its instruction to try to have the 2s. 6d. fee restored.

Yours sincerely,
(Signed) FRED J. SMITH.

108 Harley Street, W.,
May 16th, 1916.

DEAR DR. SMITH,—Cross-examining counsel loves to put to the witness in the box a question and demand a plain Yes or No. There are not many questions that can be answered thus simply. But happily your question can be truly answered in this curt fashion.

You ask: "Is it true that the deputation from the head office of the B.M.A. to the L.G.B. admitted that 1s. would be a sufficient fee for notification of infectious diseases?" I answer No, and without hesitation.

At our interview with the Government representatives we took up a definite and unassailable stand against the statement of the Retrenchment Committee that the filling of a notification form involved no more than "clerical labour worth one shilling." This statement, we maintained, showed a total lack of appreciation on the part of the Government advisers of what the notification of a disease meant and involved. We pointed out that serious responsibility was involved, and one that laid the doctor open to an action at law in case of a real or alleged error on his part. In rubbing in this statement I confined myself to my own knowledge of the notification of ophthalmia neonatorum, and the case was admitted by Mr. Hayes Fisher, the Government representative, who happened to have more than an ordinary knowledge of this disease. Not only did we repudiate the Government position, but we urged that the present fee was all too small for such work. We admitted that the same heavy responsibility did not hold in the case of the notification of measles, for no parent would be likely to be disturbed at the notification of a fever which was unfortunately held by most to be too trivial for the care of a doctor. And that as the fee for the notification of measles was already on a different basis to that of other notifiable diseases the Government might logically claim to treat it separately. But we made it clear that any exceptional fee for measles was to be considered only "as a reduction on taking a quantity," and a war economy concession, and not the concession of the professional position. I should like your permission to publish this correspondence in the medical journals.

Yours sincerely,
(Signed) N. BISHOP HARMAN.

TRANSACTIONS OF SOCIETIES.

LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD TUESDAY, MAY 16TH, 1916.

The President, DR. J. L. BUNCH, in the Chair.

DR. CHRISTOPHER-KEMPSTER brought forward the following case for consultation. A soldier *æt.* 36, who first came out in a "flush rash" while in South Africa 16 years ago; this was accompanied with sickness and vomiting which lasted from three to four hours; he then became so bad that he could not stand, he complained of headache and had to lay up because he felt so ill, this went off in three or four days. He then started peeling around the ears and neck and finally peeled all over. The scales came away in large flakes which was not repeated on any particular spot. The second attack came on six years later, and he has repeated attacks every year, generally occurring in the spring or autumn. The present attack started on May 5th, and on admission to the hospital he was peeling, his temperature was 99.6, and has been normal since. He has been treated for many diseases such

as scarlet fever, nettle rash, German measles and quinine rash.

In the discussion which followed, Dr. MORGAN DOCKRELL suggested that the case was one of erythema scarlatiniforme.

The PRESIDENT showed among other cases, a boy with keratosis-pilaris, and in contrast to this a case of parakeratosis variegata of ten months' duration, also a woman *æt.* 65 with a fungating condition on the leg; a microscopic section was shown which proved to be tubercular.

Dr. MORGAN DOCKRELL showed a case of melanotic sarcoma, which had been cured at the Radium Institute.

Captain W. GRIFFITH showed a very striking case of ichthyosis in a boy *æt.* 16.

Dr. W. KNOWSLEY SIBLEY showed a woman, *æt.* 69, with a rodent ulcer on the cheek and xanthoma on the eyelids, also a case of tertiary syphilis in a woman *æt.* 51, ulcerated lesions were present on the right cheek, spreading down the neck on to the arm and chest; the condition had been present for ten years, and the most striking feature was that the patient had never had any treatment, only what she had applied herself, which was boiling water fomentations.

Captain C. H. MILLS showed a case of syphilis complicating an eruption of lichen planus; the patient first had lichen and then contracted syphilis; the lichenoid papular rash was present all over the trunk, the patient had injections of intramine and ferrivine, and in spite of this the *Spirochaeta pallida* was found to be present in the chancre until the day the sore dried up.

Colonel HARRISON, R.A.M.C., made reference to the treatment of syphilis with intramine and ferrivine, and said that in his experience intramine was only a source of torture to the patient, and even if followed by injections of ferrivine the results were absolutely nil: he said that the point which had to be considered was whether they were justified in using intramine or ferrivine in the treatment of syphilis.

The PRESIDENT (Dr. J. L. Bunch) then read his paper entitled "Dermatitis due to Hair Dyes"; an interesting discussion followed.

SPECIAL REPORTS.

THE BOMBAY BACTERIOLOGICAL LABORATORY.

THE "Report of the Bombay Bacteriological Laboratory for 1914" (Bombay: Government Central Press. London agent: Constable and Co. 1916. Price 5d.), edited by Major Glen Liston, C.I.E., I.M.S., Director, contains accounts of much useful work. The work of the laboratory is twofold. All the anti-plague vaccine for India and its dependencies is made there, and investigations concerning plague are carried on. It is also the laboratory for preventive medicine and pathological diagnosis for the Bombay Presidency.

The total number of doses of anti-plague vaccine issued in 1914 was 812,942. It is not easy to make a just comparison as regards the incidence of the disease on the inoculated and the uninoculated, but the conclusion is come to that the uninoculated were attacked three times more frequently than the inoculated. It is easier to estimate the case mortality among the two groups, and it appears that whereas 72 per cent. of the uninoculated who were attacked died, only 20 per cent. of the inoculated who were attacked died.

Among the various studies undertaken in the laboratory were some interesting researches bearing

on tuberculosis. Having noted that tuberculosis is a rare disease among cattle in Bombay, it was important to investigate whether bacilli of the bovine type were frequently met in the disease in human beings. Fifteen strains of tubercle bacilli were isolated during the year, of which fourteen were from cases of disease of glands. In no case was a strain of bovine type encountered.

Dr. Soparkar made some interesting observations on the vitality of the tubercle bacillus outside the body. He found that when sputum was exposed to the direct action of the sun in Bombay, the bacilli remained alive for six hours, but were dead in eight hours. When tuberculous sputum was exposed in a well-lighted room, but protected from the direct rays of the sun, tubercle bacilli could be isolated from it alive six days after exposure, but all the tubercle bacilli were dead in eight days. Tuberculous sputum, when kept in a dark cupboard, although completely desiccated over lime still contained living bacilli six months after it had been deposited. These observations show that sunlight is an important agent in destroying tubercle bacilli, and that dark rooms in which the sputum of tuberculous patients has been deposited may remain infected for months.

MEDICAL WAR HONOURS.

D.S.O.

HIS MAJESTY THE KING has been graciously pleased to approve of the appointment of the undermentioned officer to be Companion of the Distinguished Service Order, in recognition of his gallantry and devotion to duty in the field:—Temp. Captain Robert McCowan Hill, M.B., R.A.M.C. (attd. 2nd Bn., Arg. and Suth'd Highrs.), for conspicuous gallantry and devotion to duty. He went to an area which was under intense bombardment, amputated the leg of a wounded officer, and attended to other wounded under most difficult and dangerous circumstances. Finally, he accompanied two stretcher cases back under shell-fire.

MILITARY CROSS.

HIS MAJESTY THE KING has been graciously pleased to confer the Military Cross on the undermentioned officer in recognition of his gallantry and devotion to duty in the field:—Temp. Captain James Lennox Stewart, M.B., R.A.M.C. (attd. 1st Bn. Gord. Highrs.), for conspicuous gallantry and devotion to duty on several occasions when tending the wounded under heavy fire. On one occasion he rallied men and set a splendid example of coolness and bravery.

FOREIGN DECORATIONS.

HIS MAJESTY THE KING has been graciously pleased to grant unrestricted permission for the wearing of the Decorations specified against the undermentioned officers' names, in recognition of their distinguished services during the campaign. Decorations conferred by his Majesty the King of Serbia on members of the Royal Army Medical Corps Mission to Serbia, March to June, 1915:—

ORDER OF ST. SAVA.

Capt. Norman Cameron, M.B., 5th Class; Temp. Capt. John Matthewson Clements, M.D., 5th class; Temp. Capt. Bernard Creasy Ewens, 5th class; Temp. Capt. Alexander Keith Forbes, M.B., 5th Class; Temp. Capt. Charles Michael Forster, 5th Class; Temp. Capt. John McAdam Hill, M.B., 5th Class; Temp. Col. William Hunter, C.B., M.D., F.R.C.P., 2nd Class; Capt. Sydney Walker Lund, M.B., 4th Class; Temp. Capt. Samuel Edward McClatchey, M.B., 5th Class; Temp. Capt. Charles Rowley Nicholson, 5th Class; Temp. Capt. Thomas Holmes Ravenhill,

M.B., 5th Class; Temp. Capt. Hugh Young Riddell, M.B., 5th Class; Temp. Capt. John Henry Victor Scott, M.B., 5th Class; Temp. Capt. Philip John Ambrose Secombe, M.B., 5th Class; Temp. Capt. Bryce McCall Smith, M.B., 5th Class; Temp. Capt. Charles Edgar Holton Smith, 5th Class; Temp. Capt. Robert Haig Spittal, M.B., 5th Class; Lt.-Col. George Elliott Frank Stammers, 3rd Class; Temp. Capt. Lewis Augustus Walker, M.D., 5th Class; Capt. Edward Sancton Walls, 5th Class; Temp. Capt. Gerald Whittington, M.B., 5th Class; Temp. Capt. John Samuel Williamson, 5th Class; Temp. Capt. William Miller Will, M.B., 5th Class; Francis Frederick Brown, Esq. (late Lt., R.A.M.C.), 5th Class; William Whiteman Carlton Topley, Esq. (late Capt., R.A.M.C.) 4th Class.

OBITUARY.

DR. JOHN HEPBURN LYELL, M.D., PERTH.

DR. JOHN H. LYELL passed away at his residence in Perth on May 12th. He had been in rather indifferent health during the past winter. Deceased was a native of Newburgh, and received his education at Perth Academy. He studied at St. Andrews and Glasgow, and qualified M.B., C.M. at Glasgow in 1896. He took the M.D. degree in 1901. For a period he acted as House Surgeon at Perth Royal Infirmary, and in 1891 started practice in Perth. Dr. Lyell was held in the highest respect and esteem in the community. In the affairs of the Infirmary he took a keen interest. For long he was the Out-door Patient Physician to the Perth Infirmary, and for the last five years he was radiologist to the institution. For the last two years he had been Visiting Physician to the Infirmary, and was in charge of the X-ray apparatus. He also held the appointment of Assistant Medical Superintendent to Perth prison, and for some time he acted as Secretary to Perth branch of the British Medical Association. He was Joint Secretary of the Local Medical Panel Committees of Perth City and County. A keen lover of science, he was identified with Perthshire Natural Science Society, and from time to time contributed papers which were informative, graphic, and of original merit. He was a member of the Röntgen Society, and an honorary life member of the St. Andrew's Ambulance Association. Dr. Lyell is survived by a widow and three children.

DR. GEO. EDWARD LANYON, M.B., C.M., J.P., FALMOUTH.

DR. GEORGE LANYON, Medical Officer of Health of the Port of Falmouth, died suddenly at his residence in Falmouth on April 17th, at the age of 50. After a medical training at Edinburgh University, he qualified M.B., C.M. in 1889. He settled in Falmouth, and soon acquired a large practice. Besides being Medical Officer of Health for the Port of Falmouth, he had recently been appointed a magistrate for the town, where he was highly respected. He leaves a widow and five young children.

DR. JAMES BRUCE RONALDSON, M.D., F.R.C.S., COLINTON.

THE death took place at Colinton, on May 17th, of Dr. James Bruce Ronaldson, who for a long period of years practised in Haddington. Educated at Belfast, Dublin, and Edinburgh, he qualified L.A.H. Dublin, L.R.C.P. and S. Edin. in 1874. In 1895 he took the M.D. St. Andrews. In addition to a large private practice, Dr. Ronaldson for many years held the appointments of medical superintendent of Haddington District Asylum, and M.O.H. for the burgh of Dunbar. He also took a deep and active interest in local affairs, and for upwards of thirty years was associated with the 8th Battalion the Royal Scots, receiving the Volunteer decoration for long service, and

latterly holding the rank of Honorary Surgeon-Colonel. Alike in private and professional circles Dr. Ronaldson was held in high esteem. He was 65 years of age, and is survived by a widow and son, who is in the medical profession, and is at present on war service.

DR. TOM ROBINSON, M.D., SPILSBY.

WE regret to announce the death of Dr. Tom Robinson, which occurred at his residence, East Kirkby Manor, Lincolnshire, a few days ago. Deceased was for many years in practice in London, and specialised in diseases of the skin and allied departments. He occupied the posts of physician to the Western Skin Hospital and other hospital appointments. He wrote some years ago a series of papers for this journal, and contributed several useful and suggestive articles to the literature of his subject in other directions. He took a great interest in the founding and the carrying on of the New London Dermatological Society, the members of which at their last meeting proposed and carried *nem. con.* a vote of condolence and sympathy with the relatives of deceased, and expressed their regret at the loss of so valued a colleague. Dr. Robinson retired into private life about three years ago, and resided at Spilsby until his death.

REVIEWS OF BOOKS.

TWO USEFUL BOOKS FOR NURSES. (a, b)

THE nursing profession is well supplied with books, and we have pleasure in welcoming new editions of two such volumes which have recently come to hand. Mr. Childe deals with a particular branch of a nurse's work—namely, surgical nursing, and he has written a book which should appeal to all nurses who take an intelligent interest in surgical work. After explaining the significance of antisepsis and asepsis in operative surgery, the author describes the preparation of patients for operations, and the after-treatment of such cases, and he discusses in detail the various duties of ward sisters, nurses, and others who may be associated in the treatment of surgical patients. The subject is very fully reviewed and all directions are clearly given. The iodine method of preparing the patient's skin for operation is enthusiastically endorsed, and we note with pleasure the author's brief explanation of Crile's theory of "surgical shock," and the measures which it entails in the preparation for operation and in the conduct thereof. The actual prescribing of drugs is no part of a nurse's duty, but she ought to know that certain drugs may be given in certain conditions and the reasons for their administration. Both these points within the limits indicated receive consideration in this volume, but we were rather surprised to find no mention of the value of pituitary extract in surgical cases. A section is devoted to operations in surgical homes and private houses, and in a short concluding chapter there are some very terse remarks regarding nursing in military hospitals. The book is thoroughly practical, and can be recommended not only to nurses but also to dressers and junior medical practitioners.

Mr. Sydney Welham's little work is an unpretentious and yet ambitious production, for an attempt has been made to cover the whole field of nursing, with the result that in parts the matter is far too condensed to be satisfactory. There are five sections—namely, Anatomy, Physiology, Medicine, Surgery, and Nursing, while in an appendix will be found some useful remarks on infant feeding, tables of weights and measures, a hospital diet scale, etc. A

(a) "Surgical Nursing and Technique." By Charles P. Childe, B.A., F.R.C.S. Eng., Lieut.-Colonel, Royal Army Medical Corps (Territorial); Senior Surgeon, Royal Portsmouth Hospital, etc. Second edition, 1916. London: Bailliere, Tindall and Cox, 8 Henrietta Street, Covent Garden. Price 3s. 6d. net.

(b) "A Manual for Nurses." By Sydney Welham, M.R.C.S., late Resident Medical Officer, Charing Cross Hospital. Second edition. London: Mills and Boon, Ltd., 49 Rupert Street, W. Price 1s. 6d. net.

glossary has been given at the end to explain terms in the text which may not have been adequately described. With the exception of a few diagrammatic temperature charts, there are no illustrations. The book is pleasantly written, and all points are clearly and succinctly stated within certain limitations.

A POCKET MEDICAL DICTIONARY. (a)

THE issue of a 7th edition of this small work testifies to its popularity. It has certainly proved its usefulness as a handy and reliable pocket reference book. It is comprehensive. We read through the "table of bacteria" it contains, and felt humbled thereafter by the extent of our ignorance. Clearly printed on good paper, the new edition should increase considerably the already large number of medical men who have found this dictionary of value.

AN IRISHWOMAN IN CHINA. (b)

MISS FRENCH went to Ningpo in 1888 to take charge of a small hospital for Chinese women. She subsequently married Dr. C. C. de Burgh Daly, and spent in all some twenty years in China, first at Ningpo and afterwards in Newchwang, where Dr. Daly held the position of Port Medical Officer. Since their return home a few years ago, she has occupied some of her leisure time in writing a singularly charming volume of reminiscences of her life in the Far East. She and her husband passed through many stirring experiences—the Chino-Japanese War, the Boxer rising, the Russo-Japanese War, and two epidemics of plague. When the great Manchurian epidemic broke out, Dr. and Mrs. Daly were home on leave, but a cablegram brought them back as fast as the Trans-Siberian Railway could carry them. Mrs. Daly describes the episodes of these adventurous times with much spirit, and we gain a deep respect for the courage and light-heartedness with which she faced dangers and difficulties. Notwithstanding the interest of her account of these stirring times, we have found Mrs. Daly's chapters dealing with Chinese life in times of peace of even greater interest. She has a great affection for the Chinese and a deep appreciation of their good qualities. It is, perhaps, her Irish blood which leaves her free of the patronising attitude of which so few Europeans can divest themselves in dealing with alien races. She appears to have been on terms of intimate friendship with many Chinese ladies, whom she found intelligent and keenly interested in European modes of life. Mrs. Daly, also, while in Manchuria, made friends of many Russian officers, military and naval, and her remarks on the complexity of the Russian character are shrewd. The same general who was with difficulty dissuaded from delivering over a whole city to loot and rapine was capable of showing the most humane consideration for an injured Chinese child. We could have wished for some more detail as to Dr. Daly's medical work, but it is only incidentally that we learn how highly it was valued both by the European community and by the Chinese.

The charm of the book is greatly enhanced by the delightful illustrations of Chinese life, most of which are reproductions of Chinese paintings. We cannot do better than recommend the book to the perusal of our readers who like a change from strictly professional reading.

THE death of Dr. John Service, a well-known medical man and an authority on colloquial Scots, is announced from Sydney, New South Wales. Dr. Service was born at Kilwinning, and was educated at Irvine Academy and Glasgow University. His best-known books are "Dr. Duguid" and "Robin Cummell," and he was the author of many sketches of social life in Scotland 150 years ago.

(a) "A Pocket Medical Dictionary: 35,000 Words." By G. M. Gould, A.M., M.D. Seventh edition, revised. Pp. 1003. 32mo. London: H. K. Lewis and Co., Ltd. Price 5s. net.

(b) "An Irishwoman in China." By Mrs. De Burgh Daly. Illustrated. London: Werner Laurie. 1916. Pp. xi, and 295. Price 18s. 6d. net.

MEDICAL NEWS IN BRIEF.

Not a Duly Qualified Doctor.

AT Linlithgow Sheriff Court on May 16th, a studious-looking man, named George Bowie Farquhar, was charged with having at Blackridge in February last pretended to Dr. William Thomas Lindsay that he was a duly qualified medical practitioner, and obtained employment as his *locum tenens* at a salary of £6 5s. a week. A previous conviction at Manchester was recorded against him. A plea of guilty was tendered, and an agent stated that accused had a knowledge of chemistry, and had taken some of the preliminary examinations in medicine. Sheriff MacLeod said he would not be doing his duty for the protection of the public unless he imposed the highest sentence of that Court, three months' imprisonment.

Russo-German Red Cross Co-operation ended.

ACCORDING to *Dagens Nyheter*, the closing of the Red Cross conference means the end of all co-operation between the Russian and German Red Cross Societies, because the German Red Cross authorities refuse to express regret for the sinking of the Russian hospital ship *Portugal*. The journal adds that the projected joint visits to prisoners' camps have fallen through.

Hampstead General Hospital.

THE Grand Duke Michael of Russia was re-elected President of the Hampstead General Hospital at the annual meeting on May 16th. In returning thanks, he paid a warm tribute to the work of the members of the medical, nursing, and official staff, and expressed his admiration of the quiet and efficient way in which they had worked, especially during the trying time of this terrible war. The institution had grown from a very small hospital into one of over a hundred beds, and of these sixty-four had been placed at the disposal of the authorities for the reception of wounded soldiers.

Administration of Tuberculosis Grant.

THE Local Government Board have expressed the view that where the primary object of an institution provided by a local authority is to deal with tuberculosis, the control of the institution does not fall within the province of the Education Committee of the authority, but comes under the control of the health department of the authority, which is charged with the treatment of tuberculosis, and that, as the administration of the tuberculosis grant is now in the hands of the Local Government Board and not of the Board of Education, they were only prepared to afford assistance in the provision of buildings to be under the control of the local authority as a health authority.

Victoria Hospital for Children.

THE annual meeting of the Council of the Victoria Hospital for Children was held on May 17th, Princess Louise, Duchess of Argyll, presiding. Mr. F. W. Hunt, Chairman of the Committee, in moving the adoption of the report, pointed out that two wards had been entirely given up to wounded soldiers during the year, and said the number of children treated had been reduced to 919. The abnormal conditions prevailing last year were reflected in the expenditure, the cost of maintenance being £1,264 more than in the preceding year. There had been a serious decrease in annual subscriptions. Her Royal Highness said she wished particularly to thank the members of the Ladies' Association for the great assistance they had rendered the hospital.

Children's Health and Food.

SIR THOMAS BARLOW, speaking at a meeting at the Mansion House, on April 25th, on behalf of the National Children's Home and Orphanage, 1,000 of whose boys have joined the colours, remarked that in these momentous days we must not only save infant

life, but have healthy children to grow into robust men and women, in order that they might fight the battle of life in conditions which they could not foresee, but which might be more strenuous than now. The open-air system had proved the value of sunshine and fresh air, but it must be supported by good food and warm loose clothing.

We were not sufficiently alive to the need for making food attractive and palatable for growing children. They did not want a lot of red meat, but what they did have should be well cooked, and accompanied by plenty of vegetables and fresh fruit. Bananas and oranges had a very far-reaching effect on the digestion. Jam, valuable as it was, was not so good as fresh fruit for children of the humbler classes, who were absolutely certain to suffer if its importation was interfered with.

Wittenberg Doctors.

IN the House of Commons on May 17th, Mr. Malcolm asked the Under-Secretary for War whether the Royal Army Medical Corps doctors, whose gallant behaviour at Wittenberg had been rewarded by His Majesty, were volunteers for that particular work or were detailed by the Germans to do it; and whether other British doctors in other typhus camps in Germany would be recommended for similar recognition.

Mr. Tennant replied: The three officers mentioned were detailed by the Germans for duty in the typhus camp at Wittenberg. My hon. friend may take it that if other officers have done equally good work they will receive equal recognition.

Tuberculous Men and the Army.

THE Local Government Board has issued a circular to town, borough, and district councils enclosing copies of an order made by the Board, whereby medical officers of health are required to furnish to the Army Council particulars of all male persons who on January 1st, 1916, were between the ages of 18 and 45, and who have been notified since February 1st, 1913, as suffering from tuberculosis.

The operation of the order is limited to the duration of the present war, and its object is to assist the Army Council in securing that men suffering from tuberculosis are not enlisted.

Swiss Hospitality for Red Cross Nurses.

The Association of Swiss Hotelkeepers has addressed a circular to proprietors of hotels asking them to give gratuitous accommodation for a period of three weeks during June, July, August, and September to Red Cross nurses on leave of all countries. It is expected that hospitality will be provided for some hundreds.

New R.A.M.C. Magazine.

THE first number of the *R.A.M.C. Depot Magazine* has just been issued at the price of 1d. The magazine is attractively got up and illustrated, and contains a number of features, including a "serial," "barrack-room yarns," an "imaginary interview," notes on sports, and general news about the corps. Members of the R.A.M.C. at home and abroad can obtain copies by applying to the office of the magazine, R.A.M.C. Depot, Aldershot.

War Medical and First-Aid Exhibition.

THE War Medical and First-Aid Exhibition, which was to have been held at the Royal Horticultural Hall, Vincent Square, Westminster, from Monday, May 22nd, to Friday, May 26th, has, with the consent of the Minister of Munitions, been postponed to July 25th to 28th inclusive.

Needy Medical Students.

At a meeting of Manchester University Court on May 17th, the Vice-Chancellor, Sir Henry Miers, announced that Mr. Sam Gamble, well known in Manchester, has set aside the sum of £5,000 to be devoted to the purpose of assisting needy medical students. It would be available for women who had passed their first medical examination, and the only

condition was that they should be Christians and total abstainers. The endowment would not be administered by the University, but by a small board of trustees. It might, added the Vice-Chancellor, be possible to elect a student under the scheme for the ensuing session.

Accident Reports.

THE Home Secretary has informed a deputation from the National Transport Workers' Federation that the proposed abolition of certifying surgeons' reports of accidents will not prejudice the general position of the workers in regard to the medical supervision exercised by the Home Office. The duties of the certifying surgeons in regard to industrial diseases will not be interfered with.

Health of Bath Rural District.

THE annual report of the Medical Officer of Health for the Bath Rural District states that the death-rate of 12.7 compares with a death-rate in England and Wales of 14.8, an average death-rate for the previous five years in Bath rural district of 11.44, and a death-rate for England and Wales, less the great and smaller towns, of 13.6. The birth-rate of England and Wales was 21.8, and the Bath rural district 24.2, the figure for England and Wales, less the great and smaller towns, being 20.7. The average for the previous five years in the Bath rural district was 20.82.

Women and War Work.

BISHOP FRODSHAM, speaking at Cheltenham on May 17th, criticised the employment of women in doing men's work in the war. He urged the necessity of safeguarding the mothers and infants in the interests of the nation. Five babies died every half-hour of each day, and this fact had a direct bearing upon the employment of women in men's work. If women's industrial work decreased the birth-rate, or if it brought about the loss of child life through neglect or any other cause, then it could not be justified in the interests of the nation. To sacrifice the capacity for bearing healthy children was an outrageous injury to the individual and to the nation.

The Cost of Notifying Measles.

AT a meeting of the Hartismere Rural District Council on May 15th, the Chairman called attention to the large expense incurred in the notification of minor diseases, such as measles. He noticed that one doctor had been paid £8. He thought that this should not be so heavy.

The Clerk said that the amount of the fee was fixed by the order of notification. Whether measles was expected or not, directly the order was issued they had about 100 cases. The doctor was paid 2s. 6d. for the notification of private patients and 1s. for other patients.

New Principal of Edinburgh University.

At a meeting of curators of the Edinburgh University on May 22nd, it was resolved to appoint Sir Jas. Alfred Ewing, Director of Naval Education, Principal in the room of the late Sir William Turner. The new Principal is a native of Dundee and an honours graduate of Edinburgh University. He held the professorship of Mechanical Engineering in Tokio University, Japan, before he was appointed Professor of Engineering in Dundee University College. From Dundee he went to Cambridge, where he left in 1903 to fill his present post. Principal Ewing has been a member of several important committees, and has written widely on scientific subjects. He enters on his new duties in October.

Dundee and Infantile Mortality.

At a meeting of the Public Health Committee of Dundee Town Council on May 18th, Mr. Paton moved that there be appointed a specialist lady doctor at a salary not exceeding £300 to supervise and control the proposed new department. They would thus secure continuity and equality of treatment, which

would at least yield them data that they could absolutely rely on in arriving at a conclusion as to whether they were getting the results they might expect. The cost of the new department would be about £1,100, and of that sum the Public Health Department would have to provide only £500 or £600.

Baillie Anderson, who seconded, said that of all the expenditure that might be admissible at such a time as this, this was an expenditure that no one who had the interest of Dundee at heart would cavil at.

The motion was unanimously agreed to.

Doctors and Panel Certificates.

THE following appears in the *Liverpool Echo* of May 18th:—

"A remarkable allegation—which will doubtless bring strong denials—is contained in the following letter:—

"The stipendiary magistrate is to be congratulated on his outspoken remarks *re* doctors' certificates of incapability. For some considerable time now doctors have, in order to please their patients, issued certificates to men and women on the slightest pretence. In fact, under the National Health Insurance certificates are issued certifying that they have to-day examined So-and-so, when they have not done so; and, further, in numerous cases these certificates are issued to messengers who call on the doctors on behalf of the patients. The attention of the local Insurance Committee is wanted in this direction.—One with Proof."

Medical Men and Compulsion.

IN the House of Lords, on May 22nd, on the consideration of the Military Service Bill, on the motion of Lord Sandhurst, a new clause was agreed to, providing that regulations made under the principal Act should provide for the establishment of professional committees to deal with claims for exemption made by duly qualified practitioners, and the recommendation of such committee should be binding on any tribunal constituted under the principal Act.

New South Shields Hospital.

WITH the object of providing increased facilities for dealing with infectious diseases, and waging a more effectual war upon tuberculosis, the South Shields Corporation have decided, when the times are more propitious, to erect a new hospital. The plans have been prepared by the borough engineer, in the light of knowledge gained through visiting some of the best hospitals in the country, and the institution will therefore be thoroughly up to date and provided with the most modern equipments.

Generally the accommodation for infectious diseases will consist of 124 beds, and for tuberculosis 66 beds. The fever patients will be treated in five pavilions, the dimensions of which will be 195 feet by 38 feet over all, and each pavilion will be provided with sun rooms and verandahs with glass roofs.

In the tuberculosis section of the institution there will be a nursing pavilion 338 feet long, and three separate pavilions for men, women and children. A sheltered playground has been set apart for children, and a large plot has also been reserved for the male patients to cultivate.

Royal College of Surgeons of England.

AT the last meeting of the Council of the College held on the 11th inst., ninety-nine candidates, having passed the required examinations, were admitted members of the College as follows:—

K. D. Atteridge, John Aydon, Hannah K. Alton, A. J. Bado, H. J. Bensted, D. S. Brachman, J. P. Bracken, I. R. R. Brogden, A. S. Carter, L.D.S.Eng., H. H. Castle, L. A. Celestin, G. E. Chissell, Hester M. Church, Mabel C. Clark, A. H. Clarke, P. S. Clarke, H. M. Cohen, W. H. Coldwell, W. M. Crombie, R. C. Davenport, S. G. Dunn, F. Dunphy, M. Dwyer, W. F. Eberli, A. W. F. Edmonds, P. O. Ellison, G. I. Evans, H. S. Evans, L. W. Evans, W. Farquharson, Guy Fehrsen, E. A. Fiddian, S. W.

Fisk, M. R. V. Ford, A. R. Fuller, D. H. A. Galbraith, G. T. Garraway, S. C. Ghose, C. C. Goodall, F. H. S. Greenish, Ethne Haigh, Edith C. Hudgell, J. C. N. Harris, S. F. Harris, A. N. Haworth, H. N. Haysom, W. A. Hotson, E. G. Howell, G. P. B. Huddy, S. Hutchinson, T. H. Jackson, B. B. Jareja, W. G. Johnston, A. M. Jones, T. Jones, V. Kameneff, T. L. Kan, R. P. Langford-Jones, E. E. Lightwood, H. B. Logan, P. G. McEvedy, S. S. Malkani, P. S. Marshall, Adeline M. Maitland, F. C. Mason, B. H. Mellon, H. W. L. Molesworth, T. D. Morgan, A. G. Morris, G. Moulson, S. Mutiah, K. V. Muttukumaru, F. Newey, D. C. Norris, A. J. Orenstein, F. C. Ormerod, P. E. Pank, G. E. Paul, R. R. Powell, J. N. Puri, H. M. Quackenbos, R. Rau Damodar, C. R. Reckitt, B. T. Rose, P. G. Russell, Violet I. Russell, M. Schwartz, D. M. Smith, W. Steadman, H. G. Stormer, G. C. Swanson, D. G. C. Tasker, H. W. Taylor, G. B. Wild, R. W. Willenberg, G. C. Williams, A. Williams-Walker, C. E. Wise, R. S. Woods.

C. H. Pywell, having fulfilled the requirements of the Dental Board of Examiners, was admitted a Licentiate.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examination, have been granted the L.S.A. diploma of the Society, entitling them to practise medicine, surgery and midwifery:—M. Dwyer, A. Glen, A. W. North, and L. F. Pain.

Royal College of Surgeons of Edinburgh.

AT a meeting of the College held on May 18th the following gentlemen, having passed the requisite examinations, were admitted fellows:—Dines C. Chakravati, L.M.S.Calcutta, L.R.C.S.Edin., William W. Hoare, M.R.C.S.Eng., L.R.C.P.Lond., M.D.Bru., George R. Livingstone, M.B., Mast. Surg., M.D.Edin., Alfred C. Sandston, M.B., Bac. Surg., M.D.Edin., Neil F. Sinclair, M.R.C.S.Eng., L.R.C.P.Lond., Herbert M'L. Staley, M.R.C.S.Eng., L.R.C.P.Lond., Muhammed A. Wajid, M.B., Ch.B., M.D.Edin.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

NOTE. CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

LETTERS TO THE EDITOR and Original Papers intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of *bona fides*. These should be addressed to the Editor at the Offices of this Journal; if in Ireland, to the Dublin Office, 29 Nassau Street; from all other parts of the United Kingdom these should be addressed to the London Office, 8 Henrietta Street, Strand.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

SANATOGEN.

AN Order has been made by the Board of Trade requiring the following business to be wound up:—

A. Wulffing and Co., 12, Chenies Street, W.C., manufacturers of Sanatogen, Formamin, etc.

Dr. T. H. M.—The London and Dublin office addresses of this journal will always be found at the foot of the last page of each issue, according to postal regulations. Letters to the Editor should be addressed as referred to at head of "Notices to Correspondents."

ANÆSTHESIA AND TRUTH-TELLING.

THE Court of Criminal Appeal dismissed the appeal of Henry James Tishaw, who appealed against a sentence of five years' penal servitude and seven years' preventive detention. The Lord Chief Justice said that the appellant in his grounds of appeal asked to be subjected to a test by chloroform, and he apparently had the impression that when he was under its influence he would be bound to tell the truth. The appellant was 46 years of age and had spent 24 years in prison.

Dr. Bruce is thanked for his communication and enclosure. The journal will continue to be addressed to the Mediterranean Expeditionary Force until contrary instructions are received.

A GERMAN MUSICIAN.

THE late Max Reger received the degree of Doctor of Medicine from the University of Berlin on the ground that his music "exercised a soothing influence on the sick." To judge from the specimens we have heard in London it might have sent even a strong man to sleep.—*The Observer*.

TUBERCULOSIS AND RECRUITING.

To prevent consumptives getting into the Army the Local Government Board are asking tuberculosis dispensary officers to assist Army Doctors in examining recruits.

BERLIN'S MOVING KITCHENS.

ACCORDING to a message from Berne, travelling kitchens have made their appearance in the suburbs of Berlin to supply the poor.

M.R.C.P. (Leeds).—The Dr. Jung referred to last week in the communication by Dr. Savill in our columns to which you refer, is a member of the Swiss Medical Faculty, a Professor of the University of Zurich, not an Austrian, as you suppose. His work on "Analytical Psychology," now translated into the English language, is most illuminating, and clearly sets forth the chief differences between the teaching of the rival schools of Zurich and Vienna.

AUSTRALIA AND PATENT MEDICINES.

THE Australian Senate has passed a Bill providing that all patent medicines imported into Australia shall bear a label showing the constituents of the medicine in general terms.

Dr. JOHN BROWN.—Your communication reached us too late for our present issue; it will appear in our next.

THE LAST STAGE!

A certain young man of great gumption
'Mongst cannibals had the presumption

To go—but, alack,
He never came back;

They say 'twas a case of consumption.—*Pall Mall*.

FLIES AND DISEASE.

WARNINGS about the danger of flies as carriers of disease germs are being issued by the Lambeth Borough Council.

DOCTORS' MOTOR CARS.

THE National Medical Union hope that the Government will take steps to reduce the duty on motor-car licences payable by the medical profession to that of 1915, and also supply the medical profession with petrol at as low a cost as possible.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 24TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE (1 Wimpole Street, W.).—4.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Dr. Michael Foster: Stick Pomanders. And other Exhibits. Papers (at 5 p.m.): Dr. J. A. Nixon and Dr. Charles Singer: Miniatures of the Bristol Guy de Chauliac MS. Dr. Charles Singer: Some Figures bearing on the Practice of Blood-letting in the Fourteenth, Fifteenth, and Sixteenth Centuries. Mr. R. R. Steele: A Note on the Scientific Work of Roger Bacon.

THURSDAY MAY 25TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY (1 Wimpole Street, W.).—8 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Clinical Cases will be shown, and anyone desiring to show cases is requested to communicate immediately with the Hon. Secretary, Dr. Hinds Howell, 145 Harley Street, W.

ROYAL SOCIETY (Burlington House, London, W.).—4.30 p.m.: Bakerian Lecture—Prof. C. G. Barkla: X-Rays and the Theory of Radiation.

FRIDAY, MAY 26TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN (1 Wimpole Street, W.).—4.30 p.m.: Annual General Meeting—Election of Officers and Council for Session 1916-1917. Cases: Dr. Eric Pritchard: Severe Rickets, Dr. W. Mitchell Smith: (1) Pigmented and Hairy Nævus with Molluscous Tumours; (2) Giantism. Dr. E. Cautley: (1) Infantism; (2) Optic Neuritis (two cases).

Mr. A. S. Blundell Bankart: Hemihypertrophy. Dr. J. Walter Carr: Juvenile General Paralysis. Short Paper: Dr. J. Lawson Dick: The Teeth in Rickets.

Vacancies.

Royal Victoria Hospital, Folkestone.—Resident Medical Officer. Salary £200 per annum, with board and laundry. Applications to Secretary.

London Temperance Hospital, Hampstead Road, N.W.—Assistant Resident Medical Officer. Salary £120 a year, with residence, board, and laundry. Applications to the Secretary.

The Royal Infirmary, Sheffield.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.

Bolton Union.—Resident Assistant Medical Officer. Salary £250 per annum, with furnished apartments, washing, and attendance. Applications to H. I. Cooper, Clerk to the Guardians, 28 Mawdsley Street, Bolton.

Bury Infirmary.—Lady Junior House Surgeon. Salary £150 per annum, with board, residence and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lanes.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Lady House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38, Barton Arcade, Manchester.

Hulme Dispensary, Dale Street, Stretford Road, Manchester. House Surgeon. Salary £250 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Secretary.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with board, rooms, attendance, and washing. Applications to the Secretary.

Royal Albert Edward Infirmary and Dispensary, Wigan.—Senior House Surgeon. Salary £250 per annum, with board, apartments, and washing. Applications to L. E. Mapei, Acting Secretary.

Gorey.—Temporary Medical Officer. Salary £146 per annum and £15 as Medical Officer of Health. Applications to R. Creighton, Clerk of the Union. (See advt.)

Appointments.

ECCLES, R. BURTON, M.R.C.S., L.R.C.P.Lond., Medical Officer for the East Riding County Isolation Hospital, Great Driffield.

HALL, O., L.R.C.P. & S.Edin., D.P.H., Medical Officer of Health for Plymouth.

MACKENZIE, FEDE M., M.B., B.S.Lond., Assistant Surgeon to the South London Hospital for Women.

Births.

COOKE.—On May 10th, at Clodiagh, Stanmore, the wife of J. Douglas Cooke, F.R.C.S., R.A.M.C.—a daughter.

FARR.—On May 21st, at Watlington, Norfolk, the wife of C. C. J. Farr, M.R.C.S., L.R.C.P.Lond., of a son.

HARKER.—On May 12th, at Chicago, U.S.A., to Dr. and Mrs. Wade C. Harker (*née* Lyla Macdonald), a daughter.

HUNNARD.—On May 15th, the wife of Arthur Hunnard, M.B., B.S., The Elms, Mansfield, of a daughter.

MALCOLM.—On May 12th, at 10 Rosslyn Hill, Hampstead, the wife (*née* Molly Scott) of Lieut. Alan Malcolm, R.A.M.C., of a son.

MILLS.—On May 16th, at 30 Heath Street, Hampstead, N.W., the wife of Lieut. E. Halford Mills, R.A.M.C., of a son.

WEIR.—On May 18th, at South Lodge, Merstham, Surrey, the wife of Walter Weir, M.B., M.R.C.S., L.R.C.P., of a son.

Marriages.

RICE-OXLEY-MILLER.—On May 16th, at St. Mary Abbot's, Kensington, Douglas George Rice-Oxley, M.B., Captain, R.A.M.C. (T.), second son of Dr. and Mrs. Rice-Oxley, 5 Prince of Wales Terrace, to Estelle Mortimer, only daughter of the late Robert Mortimer Miller and Mrs. Sidgwick, "Branksome," Ipswich.

RYLAND-MOORE.—On May 17th, at The Hirsell Private Chapel, Coldstream, N.B., Capt. Archer Ryland, F.R.C.S.Ed. and R.A.M.C. son of Mr. and Mrs. Woodcock Ryland, of 43 Holland Park, London, W., to Gladys Mary, daughter of the Rev. C. A. Moore, Domestic Chaplain to the Rt. Hon. the Earl of Home, K.T., and Mrs. C. A. Moore, of The Hirsell, Coldstream, N.B.

Deaths.

CATHCART.—On May 14th, at Greenfield, Highgate, Dr. Samuel Cathcart, aged 64 years.

GIBB.—On May 13th, at his residence, Sandyford Park, Newcastle-on-Tyne, Charles John Gibb, Esq., M.D., in his 93rd year.

RIVERS-WILLSON.—On May 19th, at Oxford, Alfred Rivers-Willson, Ph.D., L.S.A., L.M.S.S.A.

SHUTTER-HILL.—On May 16th, at 27 Warrington-crescent, Maida Vale, Dr. J. Shutter-Hill, eldest son of the late Samuel Hill, Esq., M.D., of 22 Mecklenburgh-square, aged 60 years.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MAY 31, 1916.

No. 22.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Whistling for Taxis.

ON the question of whistling for taxicabs, a correspondent sends me the following cutting from the Parliamentary Report in a daily:—
"Mr. Herbert Samuel (Yorks, Cleveland), asked by Mr. Cecil Harmsworth (Luton, L.) whether the Home Secretary had powers to prohibit the use of cab whistles in the neighbourhood of hospitals and nursing homes, said: No such power is vested in me, but a by-law made by various borough councils makes it an offence to sound a noisy instrument within a certain distance of a hospital after being requested to desist by a constable, and where this by-law is in force the police take action." My correspondent asks: "Why do not all the London boroughs revise their by-laws so as to enable the police to take action everywhere?" Why, indeed. There is scarcely a district in which this nuisance occurs which does not contain a hospital, a nursing home or a private house in which the sick and weary are tossing for sleep, and these unfortunates are permitted to be disturbed by those fortunates who have just been tossing for deal.

The Leprosy Case.

MR. JUSTICE DARLING set aside the findings of the jury in the leprosy case, saying that "he could see no legal obligation on the defendants, nor could he see any evidence to support the findings of fraud, conspiracy or misrepresentation." His lordship had left the following questions to the jury, the answers to which are appended:—

"(1) Was Mr. Miller when he took the rooms liable to infect persons or the furniture with leprosy, and did Mr. Miller or Miss Miller know this?—Yes.

"(2) Is leprosy infectious or contagious so as to be, in England, communicable from the leper to another?—Yes.

"(3) Did Miss Miller and Dr. Harbord fraudulently misrepresent that Mr. Miller was a fit and proper person to occupy the plaintiff's rooms?—Yes.

"(4) Did Miss Miller and Dr. Harbord conceal from the plaintiff that Mr. Miller was a leper, which made him unfit to occupy the lodgings?—Yes.

"(5) Did Dr. Harbord, acting as agent for Miss Miller and Mr. Miller, state to Mrs. Humphreys that Mr. Miller was not suffering from any infectious or contagious disease?—Yes.

"(6) Were these statements untrue to the knowledge of Mr. Miller, Miss Miller, and Dr. Harbord?—Yes.

"(7) Did Mr. Miller, Miss Miller, and Dr. Harbord conspire to conceal the state of Mr. Miller from the plaintiff, and make false statements to him for that purpose?—Yes.

"(8) Damages?—£250."

The facts. THE case, it will be remembered, was an action brought against Miss Miller, Mr. Bendell (as executor of the deceased Mr. Miller, who died of leprosy), and Dr. E. A. Harbord,

for breach of warranty, fraudulent misrepresentations, and conspiracy. It was alleged that the plaintiffs had suffered damage through the bringing of the deceased Mr. Miller, a leper, into the plaintiff's lodging-house. It was, of course, perfectly obvious to any medical man acquainted with the law that even if it were wrong to take a leper into a lodging-house, on whomsoever the responsibility might rest, it could not be made to rest on Dr. Harbord. Leprosy is not a notifiable disease, and in the case of a non-notifiable disease, not only is a medical man not bound to speak of it, but he is, as Sir Malcolm Morris properly pointed out, precluded by the unwritten laws of the profession from telling it in Gath. If Dr. Harbord had acted otherwise than he did, it is quite certain that the unfortunate patient, to whom alone he owed a duty (the public health was not in question), would have been harried and jockeyed from pillar to post, with the result that his sufferings would have been enormously increased. Dr. Harbord is much to be congratulated on the issue of the case; but he was fortunate in having a judge with the courage and good sense to over-rule the findings of the jury.

Trial by Jury.

IF trial by jury is to survive, the composition of juries must become more discriminate. The original idea seems to have been that a man was entitled to be tried by a jury of his "peers"—this is, his equals. The older term is now employed almost exclusively in a social sense. A

peer now means a nobleman, and it is not so very long ago since a member of the House of Lords, who was indicted for a felony, claimed the right of being tried by his "peers." Nowadays, however, intellect and education cannot be said to be the monopoly of the members of the Gilded Chamber, and anyone who is being tried on a question which involves a due appreciation of abstruse technical facts ought to have a right to a jury of his intellectual equals—men, that is, who may be presumed to have sufficient capacity to comprehend the real points at issue. In the above-mentioned case four of the jury, who, according to counsel, "have been sworn with their hats on," had been bandying about an Old Testament, calling each other's attention to the 13th chapter of Leviticus, which deals with the diagnosis and treatment of leprosy as it was known in the time of Aaron. It is a preposterous thing that medical questions in our Courts of Justice should be decided by the scientific views of Moses as interpreted in the Ghetto. You might as well summon a jury of horse-copers to decide about a submarine.

THE amusing letter of Dr. Ross, of Bedford, which appears in another column, is so personal to myself that I can scarcely avoid a reference to it. I am naturally much flattered by the suggestion that "'Sinapis' is a kind god," but while blushingly admitting the adjective, I must disavow any claim whatever to the substantive. "Sinapis" is very human—indeed, so free from god-like attributes does he seem to have appeared to some, that he has been frequently compared, and even more frequently consigned, to the devil. Dr. Ross's surmise that the B.M.A. has in the past applied a sinapism to "Sinapis" is not correct, nor is it right to assume that because I find a great deal to criticise in one of the many spheres of the Association's activities, I am unable to find a good word for it in any of the others. I am, on the contrary, very willing not only to admit, but even to affirm, that in matters purely scientific the Association has done very good work, and if it were to confine itself to the encouragement of research and the advancement of knowledge there would, in these columns at any rate, be nothing but praise for it.

WHATEVER its original intention may have been, the Association is to-day far more a politico-ethical organisation than a scientific body, and it is from this plank of its composite platform that it now stands and appeals, and it is consequently on this plank that it must be judged. I am not for the moment concerned with the blunders, the *lâches*, the tergiversations which have punctuated its political progress, nor need I further insist upon the brummagem bounce which it mistakes for playfulness, or the suburban sermonising which is its sorry substitute for seriousness. I am merely insisting that as the question at issue refers to its political activities, it is irrelevant to urge that in some other directions there are points which may be counted to it for righteousness. Macaulay says of Charles I., "We charge him with having broken his coronation oath, and we are told he kept his

marriage vow. We accuse him of having given up his people to merciless inflictions; and the defence is that he took his little son on his knee and kissed him. We censure him for having violated the Petition of Right; and we are informed that he was accustomed to hear prayers at six o'clock in the morning." The B.M.A. may be possessed of all the domestic and parochial virtues, but its essays in statesmanship have been disastrous.

**Mending
or
Ending.**

DR. Ross complains that I am purely iconoclastic, that my notes lack a constructive policy. If I am to be judged entirely by what I have written about the B.M.A., there is doubtless much truth in this contention. My defence is that by endeavouring to point out the political incompetence of the only existing medico-political organisation, I was trying to persuade my readers that if their interests are to be defended in the future they must look beyond 429 Strand. I may be asked, "Why not mend the B.M.A.?" To this I would reply that, in my humble opinion, for political purposes, it is past mending. It is in the wrong hands. It is only incidentally political. It is neither fish, flesh, fowl, nor good red herring. It is not only incompetent and dunderheaded; it is worse: it is self-satisfied in its incompetence and dunderheadedness. It learns nothing: neither tactics nor manners. It has no settled policy; it is purely opportunist. So far from uniting the profession it succeeds only "in intensifying old animosities and creating new ones." If we are really to be in earnest about meeting the next medical Bill as it ought to be met, we must get rid of this floundering incubus and set up in its stead something which will represent us with dignity, energy and understanding.

**The
Substitute.**

I AM not for the moment prepared to say what that "something" should be, but of one thing I am convinced—namely, that it should be a body whose sole *raison d'être* would be political, whose executive would be chosen from among those who have some practical acquaintance with affairs, with the time, experience and energy to defend the large interests of the profession; watchful, far-seeing and resourceful. I hoped, and am still hoping, that the Panel Medico-Political Union will be able so to revise its rules and its views as to open the door to every qualified person, man or woman, in the British Isles, and to extend the sphere of its activities so as to comprise every politico-medical question, whether connected with the Panel or not. A cursory perusal of the rules of Dr. Weply's Union, which I received last week, does not leave the impression of any insuperable difficulty, but on such a question my opinion is valueless.

**Medico-
Political
Union.**

OF the letter which appeared from Dr. Weply on page 473 of our last issue, I am free to confess that I do not find it altogether explicit upon the point which, by implication, I put before him. He says that the membership of the Panel Medico-Political Union is open to any duly qualified medical practitioner, but goes on to

admit that the Union "have not, in practice, upheld the candidature of any member of the profession who is not engaged in panel practice; that in the opinion of the Executive "panel matters should only be discussed by panel men, and that an independent organisation is an absolute essential." Whilst I am ready to concede that the interests of panel men are best considered and managed by those directly concerned, I cannot find therein a good reason for a separate and distinct organisation. It seems to me that a body which included all medical practitioners might for executive purposes easily be divided into more or less independent committees, whose findings on points exclusively within their respective departments should be final. There could thus be a Panel Committee, a Tuberculosis Committee, a Health Committee, and the like, each of which would be paramount in its own sphere of influence. *L'union fait la force*, and it would be a grave mistake to multiply defensive organisations at this juncture. The Panel Medico-Political Union seems to me to have the germs of a really beneficent body. But from Dr. Welch's letter it appears obvious that if it is to "man the trenches" it must consent to become more catholic.

In the letter of Dr. John Brown, which appears in another column, **Direct Representatives**, our readers will find another and a very important count in the indictment which is growing against the British Medical Association. From this letter it would seem that it is the policy of the B.M.A. to use its machinery for the purpose of capturing the direct representation of the Profession on the General Medical Council. That, of course, is very human, but it is not in the interests either of the profession or the public that it should be tolerated. There are but four direct representatives for England and Wales, one for Scotland, and one for Ireland. Of the other 33 members, five are appointed by the King in Council and the remainder by the various Universities and other qualifying bodies. The bulk of the working members of the profession have thus but six real representatives allotted to them. According to Dr. John Brown these six are now nothing more than nominees of the British Medical Association, a body which, on a generous estimate, does not contain one-third of the profession. This is an additional reason for setting up a new body.

Surgeons and Petrol. ON two successive days in last week the correspondence columns of the *Times*, in two letters, supplied a useful commentary upon the subject upon which, with the customary vigour, "S.O.S." addressed us in our last issue. The first was signed by "One who is obliged to Economise," the gist of which is contained in the following citation: "Last week a luxurious six-cylinder car, containing two ladies, arrived at Harrow for the purpose of buying a small dog." (I did not know that motor-cars bought dogs.) "They had motored from beyond Bristol—130 odd miles at least. And, having bought their dog, returned home the same afternoon. Two hundred and sixty miles, costing in petrol alone quite £3!" The following day there appeared a letter signed "M.D.," in which the signatory says: "I reside in a South Coast watering place which at the present time is full of people using pleasure cars.

Personally, although I am surgeon to a large military hospital and have charge of two important departments, I experience considerable difficulty in obtaining petrol. Often I am unable to obtain more than a can at a time, and to-day was told that if I offered £1 for a can I could not be supplied, because the visitors had bought up all the petrol in the town."

It is a grave scandal that doctors, who are not only the least luxurious and—nowadays, at any rate—the hardest-worked members of the professional classes, but admittedly those upon whom the health and well-being of the community depend, should be restricted in petrol when luxurious ladies are allowed to travel 260 miles for the purpose of buying a dog. I wonder how much was paid for that dog, and I wonder, too, how much it will cost these ladies to keep it. There is a good deal of sentimental nonsense talked about the magnificence of women in war time. The nonsense is usually chanted in a shrill advertising treble or intoned with snuffles and unction by the castrates who conscientiously object to men being men and women women; but chant and intone as they will, these people cannot conceal the fact that there are hundreds of women in this country whom the war has not touched in any degree, women who motor and buy dogs, who overfeed and overdress themselves exactly as they did before the war, and who will continue to do these things unless or until they are legally prevented from so doing. When the snufflers and advertisers express surprise at the right type of Englishwoman being ready and willing to do her obvious duty as a woman in a time of national crisis, they are offering the worst insult to the sex which it would be possible to devise. Self-respecting, loyal and patriotic women work because they feel a call to work and not because they hope after the war to use their war services as a lever for obtaining political concessions. If these chanters and intoners would go to France they would see what women who are in earnest will suffer and sacrifice, not for possible reward, but for that real love of their *patrie* which characterises the race. I beg to acknowledge the receipt of a letter from Mr. Eustace Miles on the rather paltry question of his qualifications as a dietetician, with which I may possibly deal next week.

Sir James Goodhart. THE profession will experience a feeling of very genuine regret at the announcement of Sir James Goodhart's death. The loss of his devoted wife a short time since dealt him a blow from which he never recovered, for although he has worked on steadily, he felt, as he recently expressed it to me, that the aching void was increasing rather than diminishing. James Goodhart was a fine type of physician, accurate in diagnosis, resourceful in treatment, helpful in difficulties, sympathetic with the suffering and courteous to colleagues. He was among the few medical writers of his day (they are even fewer now) who had any real sense of literary balance. His writings were always worth reading, if only for their style; but inasmuch as his rich fund of natural humour pervaded everything he wrote, he was one of the most popular, as well as one of the most instructive writers of his time. His little book on "Some Common Neuroses" is one which every medical man should read, especially every young medical man. Guy's Hospital will now add another to the already long list of departed physicians who have contributed to its renown, the name of one who not only in learning, but also in that which is even more important—namely, in character and influence, was really a great and good man.

SINAPIS.

CURRENT TOPICS.

The Chair of Surgery in Trinity College, Dublin.

THE appointment of Mr. Edward H. Taylor as Regius Professor of Surgery in the University of Dublin necessitates his vacation of the Chair of Surgery in Trinity College which he has occupied with much distinction since the death of Mr. E. H. Bennett. Hitherto it has been one of the duties of the Professor of Surgery in Trinity College to act as surgeon to Sir Patrick Dun's Hospital, but the present appears to be an opportune time for the Board of Trinity College and the Governors of Sir Patrick Dun's Hospital to consider the advisability of altering this arrangement. There is no doubt that if the candidates for the Chair of Surgery were to be drawn from a class of surgeons who were not already possessed of hospital appointments in Dublin, the allocation of beds in Sir Patrick Dun's to the College professor would be a great advantage to the Board of Trinity College. But, as a matter of fact, the most eligible candidates for the chair are certain to be surgeons who already hold hospital appointments which they are unwilling to give up in order to migrate to Sir Patrick Dun's. The net result, as far as Trinity College is concerned, is that, if the surgeony of Dun's is to be still attached to the Chair of Surgery, the field of candidates for the chair will be limited to those who are either too young or of too little standing to have already won hospital appointments. The choice will, in fact, be unduly and improperly limited, to the detriment of surgical teaching in the School of Physic. From the point of view of the Governors of Sir Patrick Dun's Hospital, the advantages of dissociation appear to be equally clear. It is unsatisfactory for the Governors not to be masters in their own house, and not to be in a position to choose their own staff. As things are at present, they have to take most of their staff on the appointment of outside bodies, and they cannot, for example, consider the claims to promotion of their assistant staff. This does not tend either to efficiency or to contentment. We understand that there is no legal difficulty in dissociating the surgeony from the chair; the Board of Trinity College and the Governors of the Hospital can make the same arrangement as has been in force for many years in regard to the Chair of Anatomy and Chirurgery. The Professor of Anatomy and Chirurgery is also *ex officio* Surgeon to Sir Patrick Dun's Hospital, but he is not merely permitted, but compelled, to declare that he will neglect his duties as surgeon. The Governors of the Hospital have then the power to appoint a deputy. We hope that a similar arrangement will be made in regard to the Chair of Surgery, if, indeed, the College and Hospital authorities do not consider the present a suitable opportunity for reviewing their relations in their entirety.

The Prophylactic Use of Tetanus Antitoxin.

TREATMENT by prophylaxis is one of the most remarkable advances in medical science emphasised by the present war. The most encouraging results have attended the use of tetanus antitoxin as a prophylactic measure, as the subcutaneous injection of twenty units immediately after the injury almost certainly prevents the development of tetanus. Yet the form of treatment is not by any means ideal. The antitoxin will protect for a short period only, variously estimated as from 8 to 20 days; whereas if administered after injection a delay of a few hours may prove fatal; and again, a repetition of

the injection is not generally practicable owing to the danger of anaphylaxis. Professor H. E. Robertson, of Minnesota, has studied the subject in great detail whilst working in the University of Freiburg, and he published a discussion of his results in the current number of the *American Journal of the Medical Sciences*. Having particularly tested the various methods of administration, and having sought to discover the reasons of failure in those cases where the antitoxin has proved ineffectual, he has arrived at the following conclusions:—The antitoxin is far more slowly absorbed than the toxin, therefore it should be administered either intravenously or subcutaneously. If this be impracticable, then a pad soaked with antitoxin and applied directly to the wound will protect if it can be brought into contact with every part of the wound, and if there be no delay in its application. Antitoxin in the form of a dry powder does not protect, for it cannot be absorbed. The only type of case in which this has proved useful is in the prevention of tetanus neonatorum, and this is probably because absorption takes place so much more readily in young subjects. Robertson uses pads previously soaked with antitoxin and dried in an oven, and when required for use moistens them with any sterile fluid, preferably saline, this only as a temporary measure until a subcutaneous injection can be given. The most important cause of failure is the very rapid formation and absorption of the toxin. Donitz injected mice and rabbits with the toxin and came to the conclusion that in cases of severe poisoning the lethal dose of toxin was already combined with nerve structures at the end of five to eight minutes. The combined toxin cannot be neutralised by the antitoxin, hence the urgency in the use of the latter. Cases of delayed tetanus where the incubation period is very prolonged occur from time to time and have not yet been explained. No safe method of active immunisation has as yet been discovered owing to the dangers associated with tetanus toxin. Until this is done prophylaxis cannot be assured.

King Edward's Hospital Fund.

A CHERFUL note pervaded the speeches at the annual meeting of the Governors and General Council of King Edward's Hospital Fund for London, which was held at St. James's Palace on May 24th, under the presidency of the Speaker of the House of Commons, Mr. Lowther. This was justified abundantly by the reports of both Secretary and Treasurer. In presenting the accounts and balance-sheet for 1915, the Hon. Treasurer, Lord Revelstoke, referred to the fact that the income from investments was over £97,000, the largest ever reached. This was largely due to the receipt of the first instalment of the legacy of Sir Julius Wernher. The Fund held a large amount of War Stock, Treasury Bills, and Exchequer Bonds. His Lordship referred to the munificent bequest, made this year, of the residue of the estate of the late Dowager Lady Wilton. The total was expected to amount to about £150,000, and already the Fund had benefited to the extent of £100,000. The draft report of the Council was presented by Sir Savile Crossley, the Hon. Secretary, and showed total receipts of £226,779, of which £12,949 were contributions to capital. The general account total included a special donation from Sir Ernest Cassel of £28,000 4½ per cent. War Stock.

The report went on to state that the total sum distributed among hospitals, convalescent homes, and consumption sanatoria during the last ten years was £1,484,750. Since the foundation of the Fund £2,098,416 has been distributed. The first million was passed in 1909, the thirteenth year of the Fund.

It had taken six years for the grants to reach the second million. The average annual distribution for the whole period of 19 years has been £110,442. During 1915 the amount spent on administration was £3,205 16s. 1d. The average yearly outlay in this respect was £2,819. The League of Mercy had again contributed £14,000, making a total of £230,000 which it had given to the Fund since 1899. A further £6,300 had been received from the Wernher estate, making a total of £320,015.

The Speaker, replying to a vote of thanks, said he thought they must be prepared to find that, as war continued, the margin of eleemosynary funds available for the general charities of the country would shrink to a considerable extent.

Our readers will agree that the report is a very satisfactory document, and we trust this great charity will continue to receive the large measure of support it requires for the proper discharge of its onerous duties.

Indian Medical Appointments.

It was recently announced in the Press that after the open competitive examination held last July for admission to the Indian Medical Service, no similar examination would be held during the continuance of the war, but that such appointments as might be required to meet the absolutely indispensable needs of the Service would be made by nomination by the Secretary of State. To assist him in making these appointments which, as already announced, will be limited in number to the absolutely indispensable needs of the service, Mr. Chamberlain has appointed a Selection Committee who will summon and interview such applicants as may appear to be *prima facie* suitable, and make recommendations for appointment. Applications for appointment should be addressed to the Secretary of the Military Department, India Office, Whitehall, London, and should contain concise particulars of the applicant's medical degrees and career. Applicants must be over 21 and under 32 years of age at the time of application. Particulars regarding pay, promotion, etc., in the Service can be obtained from the Secretary, Military Department.

Rest.

STANLEY ABBOT, of Massachusetts, estimates that 20 per cent. of insane persons become so from want of rest of body, or more particularly of mind. Moreover, in the same percentage, he believes a series of prodromata to obtain, easy of recognition, and most imperatively to be obeyed. These vary, in the one case manifesting themselves as an inexplicable and ingravescent laziness in a subject heretofore conspicuous for industry; in another, functioning paradoxically to produce a feverish appetite for work, combined with a strong distaste for any form of inactivity, physical or mental, and a belief that hours spent in all forms of suspension are criminal. He further disputes the prevalent opinion that change of occupation constitutes recreation; such a belief of itself implies an incapacity truly to rest. Study of the healthy child tends to confirm such conclusions. It is a matter for much marvel how a boy will contrive to pass an entire day frequently employed in doing practically nothing, yet will retire to bed at night with an astonishing avidity for sleep and a profound sense of a well-spent twelve hours. The commonly deplored slackness of the young adolescent may, in this light, be an instinctive conservative process. Such individuals, when placed in *medias res*, frequently display much acuity and promptness of mentality, a striking contrast to the jaded conclusions of the overworn. Abeyance of all function save the essential is to be seen even

in such temperamental beings as birds—over prolonged periods. The generations become more and more "troubled about many things," drifting further and further from what has been styled "the eventual element of calm."

Minor Cases.

STUDY of the clinical assortment constituting an extern surgical-dressing department is not devoid of instruction. Frequently, from the lack of continuous or systematic treatment, the absence of control over the patient's domestic circumstances, together with the necessity of cramming, it may be a hundred cases, into the space of a few hours—such so-called minor cases come to assume an inexorable chronicity and refractoriness which cause them to become of truly major importance. A neglected or mistakenly opened whitlow lacks the dramatic clinical urgency of an acute osteomyelitis. But its effects, resulting from faulty drainage or imperfect immobilisation, are deleterious and debilitating to a degree. Moreover, in cases where such departments are administered by resident officials in turn, from day to day, continuity of treatment, as regards the therapeutics employed, is not exercised. We have ourselves experience of one case of obscure chronic ulceration of the lower extremity, which had presented itself at the extern department for a period extending over seventeen years, without a cure being effected. Yet so great is the demand upon the hospital accommodation for cases of immediate or vital urgency, that these poor lesser pathological fry must perforce remain where they are.

PERSONAL.

SIR ARTHUR CHANCE has been elected Consulting Surgeon to Dr. Steevens' Hospital, Dublin, in room of the late Sir Charles Ball.

ON June 23rd, Sir John Bland Sutton will deliver the Cavendish lecture of the West London Medical-Chirurgical Society at the West London Hospital.

THE appointment is gazetted of Surg.-General Sir William Babbie, V.C., K.C.M.G., C.B., M.B., K.H.S., to be a Director of Medical Services at the War Office.

DEPUTY SURGEON-GENERAL D. J. P. McNABB has been appointed to the Medical Department, Admiralty, as Deputy Director-General, and Fleet Surgeon J. F. Hall has been appointed to the Medical Department, Admiralty, as Assistant Director-General.

THE President and Council of the Royal Society have awarded Miss Dorothy Dufton, of Girton College, Cambridge, the first year's income of their Lawrence Fund for an investigation of pneumonia produced by poisonous gases. The income of the Lawrence Fund is devoted to research in the relief of human suffering, and amounts to about £160 per annum. Miss Dufton is the daughter of Dr. S. F. Dufton, Inspector of Schools in Leeds, and is at present doing research work in Cambridge University Physiological Laboratory.

COMMISSIONERS under the Military Service (Civil Liabilities) Act for making grants to men on service are being appointed, and will enter upon their duties almost immediately. Dr. Tinsley Lindley has been appointed to act as Commissioner for the whole of Nottinghamshire, including the city. The duty of the Commissioner is to investigate applications for assistance, to satisfy himself as to the accuracy of the statements made by the applicants, and to report, with recommendations, to the Central Committee.

FRENCH CLINICAL LECTURE

ON

TUBERCULOSIS OF THE FOOT.*

By PROFESSOR KIRMISSON, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HERE are two small boys with tuberculous mischief of the bones of the foot and dorsum, an affection which is very common in general practice and with which therefore it behoves us to be familiar. The disease presents itself in various clinical types, as I shall explain in the course of my remarks.

The first of our little patients is eight years of age and his family history at once suggested the possibility of tuberculous mischief inasmuch as his father is a "cougher," as is also the patient himself. He was born prematurely at the eighth month of pregnancy and had a bad attack of enteritis when seven months of age. The trouble in the foot set in about three months since with swelling in the region of the right malleolus. This seems to have come on without any known cause, there being no history of previous injury, and it was not accompanied by any pain or functional impairment.

The skin over the swelling is normal, presenting no redness or thickening or tendency to adhesion. The swelling is oval and is situated in front of the tibial malleolus. It measures an inch and a half in length, is of soft consistency and is slightly tender on pressure. The movements of the tibio-tarsal joint are intact, and on making him lie down we see at once that the two retro-calcanean hollows are free. It follows that the lesion does not involve the articulation, a point to which I shall have occasion to refer later on. Lastly, to complete our examination, we must note the presence of an enlarged gland at the apex of Scarpa's triangle and an expiratory murmur over the fourth dorsal vertebra, indicating the existence of tracheo-bronchial adenopathy. You will see then that there is no limitation of movement or displacement of the foot, and that the swelling is unilateral.

It is to be remarked that a few hours' rest is followed by noteworthy diminution of the size of the swelling, a circumstance usually met with in cases of this kind.

The symptoms then point to the existence of osteitis involving the external malleolus. In view of its insidious onset, its essentially chronic course, without any constitutional or local reaction, we have no difficulty in arriving at the diagnosis of osteitis of tuberculous origin.

I must point out, however, that the chronic course of a given case of osteitis is not *per se* proof of its tuberculous nature, for there are many forms of osteomyelitis which are essentially chronic *ab origine*. These affections, which are in no wise related and have nothing in common with tuberculosis, were first adequately described by Trélat. I met with a case of the kind about four years ago in a young man, 26 years of age, who had served in the cavalry. This patient had suffered for a long time from trouble in his right foot, and as he had never had any sharp pain or fever it was thought to be tuberculous. He was operated upon and we came down on an abscess, the pus from which on cultivation showed

staphylococci. It was a case of osteo-myelitis of the internal malleolus, chronic *ab origine*. In this case the radiograph shows very distinctly a white patch indicating the presence of an abscess.

The other little patient, six years of age, born at term of healthy parents, brought up on the bottle, has had measles, small-pox and diphtheria, and every winter he has a cough.

A fortnight before admission his mother noticed that his foot was turned out in valgus when he walked and there was a swelling on the inner side. There is deep-seated thickening in the region of the medio-tarsal articulation, and twisting the foot causes some pain. The tarso-metatarsal joint, on the contrary, is free from pain and tenderness. Lastly, there are several glands in Scarpa's triangle as well as in the cervical and axillary regions. In this child the lesion is situated in the second row of the tarsus on the inner side, and I shall explain shortly why this should be the preferential seat of tuberculous osteitis.

The diagnosis of lesions of the tarsus and dorsum of the foot is based on two considerations, *viz.*, the nature of the osseous lesions and their distribution. The nature of the lesions is inferred from the clinical appearances, more particularly their pasty fungous consistency and the discovery of enlarged glands. You are aware that coxalgia is accompanied by the presence of enlarged glands in the internal iliac fossa and, similarly, tuberculous osteitis of the knee and foot are almost always associated with glands in Scarpa's triangle.

The course of the disease might lead us astray because there are forms of osteomyelitis which are chronic *ab origine*, while, on the other hand, tuberculous osteitis sometimes runs a hyperacute course. I can recall a case of coxalgia which started with a temperature of 105° F. Nevertheless a slow, chronic, insidious course militates in favour of tuberculosis. Another argument in favour of this diagnosis is the discovery of tuberculous lesions elsewhere.

The second part of the diagnosis, based on the situation of the lesions, infers exact anatomical knowledge. Tuberculous lesions of the dorsum and tarsus are specially apt to occur in three spots, *viz.*, the tibio-tarsal articulation, the posterior half of the tarsus (astragalus and calcaneum) or in the anterior half. In adults and in elderly persons all these joints may become involved simultaneously.

In determining the exact seat of the mischief we must take into consideration the site of the swelling. If the swelling is in the region of the malleoli, it is a case of malleolar osteitis involving the tibia or the fibula as the case may be. If behind the malleoli it may be a case of synovitis, but though it is common enough in adults for the synovial sheaths to be involved, it is much less frequent in children. Nevertheless, last year I came across a case of tuberculous synovitis in the sheath of the tibialis anticus in a girl.

The swelling may be unilateral or bilateral. This enables us to distinguish malleolar osteitis from tibio-tarsal arthritis. In presence of

*Delivered at the Paris Hospital for Sick Children.

arthritis the fungous outgrowths tend to project between, in front of and behind the malleoli, because the joint is bounded laterally by the malleoli and the strong lateral ligaments, and in front by the tendons of the tibialis anticus, the extensor proprius pollicis and the extensor digitorum communis.

Tibio-tarsal arthritis then is manifested by two lumps separated by the tendons of the anterior part of the leg and behind by the two fungous masses on each side of the tendo Achillis. In these cases, moreover, the movements of the joint are limited and the foot assumes a faulty position intermediate between flexion and complete extension. The foot tends to fall and, after a time, retraction of the tendo Achillis leads to permanent equinism in a certain proportion of the patients.

I should add that in most instances changes in the astragalus characterise the onset of tibio-tarsal tuberculous arthritis. These changes, however, do not necessarily involve the joint. The astragalus is made up of two segments, the astragaloid pulley which forms part of the articulation, and the head of the astragalus, which is outside the tibio-tarsal joint and belongs entirely to the articulation of the first and second rows of the tarsus. The head of the astragalus may likewise be the seat of tuberculous mischief.

Tuberculosis, however, displays a marked preference for the calcaneum. This seat is recognised by the swelling in the depressions on either side of the bone and ultimately by reddening of the skin and fluctuation.

In some instances the disease involves the second row of the tarsus as in our second case. In this event the lesion usually affects the point of maximum movement, *viz.*, the internal half (scaphoid, articulating with the astragalus and the three cuneiform bones, the latter articulating with each other). This remark applies to lesions of the elbow which tend to involve the external aspect (centre of the movements of flexion, extension, pronation and supination).

Apart from the seat of the swelling, we must investigate the movements in endeavouring to determine the seat of the lesions. The movements of the tibio-tarsal joint are especially flexion and extension, and it is limitation of these movements that is met with in tuberculosis of the tibio-tarsal joint. The movements of abduction and adduction belong to the sub-astragaloid articulation, and those of twisting to the medio-tarsal joint.

Treatment.—Speaking generally, it may be remarked that tuberculous disease of the foot and dorsum is among the least unfavourable forms, because it has a tendency to yield to conservative treatment, and when this fails it yields readily enough after operation. The prognosis is certainly better than in tuberculous arthritis of the elbow or knee or in coxalgia.

When the patient comes to us with the foot in a faulty position, the first thing to do is to restore it to its normal relationship with the leg. This can sometimes be done by mere reposition, but it may be necessary in certain cases to divide the tendo Achillis, after which the foot must be maintained in a proper position by means of a light plaster splint, leaving the lesions as far as possible uncovered.

When the patient comes with abscess formation, as in these two cases, the usual practice is to have recourse to deep ignipuncture, a method which is of veterinary origin, and has only become safe and useful since the introduction of asepsis and the thermo-cautery. The patient is anaesthetised, and, having sterilised the skin, we make thirty or forty

stabs with a fine platinum cautery needle into the swelling.

In presence of suppuration, we must deal with the case as we should with an abscess of whatever origin—by puncture, followed by the injection of iodoform ether. In more advanced cases tunnelling of the astragalus gives excellent results. Partial and total tarsectomy generally prove successful. Patients treated in this way usually walk well, provided we take care to keep the foot at a right angle with the leg.

ORIGINAL PAPERS.

ATROPHODERMIA RETICULATA SYMMETRICA FACIEI.

By GEORGE PERNET, M.D.,

Dermatologist to the West London Hospital and Lecturer on Dermatology, West London Post-Graduate College.

THIS is a condition which has apparently not been described (I am open to correction), and to which I have given the above descriptive name as a provisional label, but I have no doubt that it has been observed by others. Indeed, I have seen one or two examples of it myself, but as it is uncommon in my experience I have thought it advisable to christen the condition in order to call attention to it. Perhaps readers of this journal in general practice may have seen similar cases. This skin affection, being more or less a trivial one, may well pass unnoticed or not be troubled about when seen. As regards the present case, I am indebted to Mr. Oswald L. Addison, who has the patient under his care for

scioliosis, for sending the child on to my department as something a little unusual from the skin point of view.

The patient is a girl, aged 12½, and, according to the mother, there was nothing the matter with the skin, which was good, until she had measles very badly at the age of four. As a sequela, the skin of the face became rough and remained so until about a year ago, when the two cheek areas began to take on their present appearances. There has never been any sign of ulceration or pustules about the affected areas. Last Christmas (1915) the child had an attack of German measles, but the eruption was not at all bad on the face. Cold winds made the areas red. Nothing had ever been applied to them in the way of treatment.

The affected areas of the cheeks are roughly triangular and more or less symmetrical, not strictly so in the Euclidean sense, but sufficiently to be described in that way for our purposes. The distribution is shown in the reproduction from a photograph.

The parts are slightly reddened and have a honeycombed appearance. On close examination with a lens a superficial atrophy of the skin can be made out. The picture is that of a fine net-work, the meshes of which form a raised, delicate tracery enclosing slightly depressed atrophic areas. At the borders of the patches small pinpoint depressions could be seen. The slight, bluish redness is due to a certain amount of telangiectasis here and there, especially about the margins of the affected areas. With the exception of a slight degree of xeroderma about the legs, the patient's skin generally is good.

The condition is admittedly a somewhat trivial one in itself, though in a girl and situated on the face it has its importance from the æsthetic point of view. La Rochefoucauld has said that: "Nous avons tous assez de force pour supporter les maux d'autrui," but a young woman with a blemish of this kind would consider it under a very different angle, and would not be as philosophical about it as the detached onlooker.

THE MEDICO-LEGAL ASPECT OF GUNSHOT WOUNDS.

By J. C. McWALTER, M.D., LL.D., R.A.M.C.

EVEN doctors sometimes pray. Not often, perhaps, or for long. And on occasion they ask pardon for offences. One of the crimes of which they are often guilty is to swear, boldly and confidently, what is not true. One means that medical men make statements on oath which they doubtless believe to be true, but which are really founded on assertions embalmed in text-books originally written forty or fifty years ago. Such teaching was possibly true at one time and under certain conditions which then prevailed. Such assertions ought no longer to be seriously made in the Courts unless they are within the personal knowledge and experience of the witness, or have been checked or verified by recent observations.

Startling statements are sometimes made in our Courts about gunshot wounds. These have become unpleasantly familiar in Dublin of late, and it is desirable to review them from the point of view of medical jurisprudence.

It is stated in text-books and sometimes sworn in Court that the wound shown on the dead man cannot have been fired at close range, because there was no charring of the clothes or of the surface of the wound. Clearly it may be a matter of life and death for an accused person to prove whether a fatal shot was fired at close or distant range, and it is well, therefore, to be accurate in one's statements.

I have quite lately examined cases of fatal gunshot wounds, where the firing was at close range, and in no case was there charring either of the clothes or the skin. I think the statements about charring were true in the old gunpowder days, but that it never occurs in modern rifle firing with modern ammunition.

One ought, of course, to be very guarded in making dogmatic statements, and one must give as accurately as possible the conditions under which one's observations were made.

The cases which I examined were seen by me from half an hour to two hours from the time of death. The weapon was the ordinary service rifle,

and the ammunition the ordinary Mark VII bullet—also called 7.7 m.m., or .303 gauge. They occurred within the limits of a room, probably nine feet.

It must be noted that the appearance and characters of a gunshot wound will vary according to such a variety of circumstances that it is most difficult to determine everything from mere *post-mortem* examination. The wound will vary not only with the weapon—revolver, rifle, carbine—but also with the description of ammunition—its bore, .275 or .303—or with the flat-pointed German bullets described as Dum-Dum, or if by some of the Italian ammunition. The size, shape and composition of the bullet, and the explosive—whether it be gunpowder or one of the modern high explosives, and the part struck, whether bone or soft tissue, will, of course, modify the result. The velocity of the projectile will depend partly on the explosive and partly on the distance, and will also influence the result.

The nature of the gunshot wound will vary, therefore, with the part of the body struck, with the shape and even position of the missile, with the obstruction met with in the course of the bullet, with the nature of the explosive, and with the degree of velocity.

Old-time traditions of the text-books that a gunshot wound fired at close range exhibited blackening and charring of the clothes and of the wound merely lead one astray. The most reasonable tradition was that the wound of entrance was small and inverted, the wound of exit large, jagged, and everted. Caspar, whose work is such a storehouse of knowledge on the questions of medical jurisprudence, long ago doubted this teaching, and even asserted that in certain instances the wound of entrance was large and that of exit small.

In my experience with modern rifle bullets, Mark VII, at close range, the wound of entrance and the wound of exit are alike small, without any charring or marked inversion or eversion, when the shot goes through the hand or wrist. Where the shot penetrates the thorax, from before backwards and obliquely, the wound of entry is small, very slightly inverted, with no charring and no external sign of hæmorrhage. The wound of exit is large, approximately triangular, and with little or no eversion, and very little hæmorrhage. It is rather more like a bayonet wound.

There is no sign of charring on the clothes, either at entrance or exit. They look as if slashed with a sharp knife. There may be no sign of blood on the torn clothes over the wound of entry.

One constantly reads about the danger of bullet wounds from the particles of clothing carried into the wound. I doubt if particles of clothing are ever carried in, unless by stray bullets. The clothing, in the cases I examined, was simply cut aside out of the way by the velocity of the bullet, and showed no indication that any part was carried in. Copious internal hæmorrhage determined death. The quantity of blood that flows out of the wound of exit some time after death is very great.

Where death occurs from heart wounds there is, I think, generally an expression of anguish. Where the fatal injury has occurred to the brain, the face may be stereotyped into a smile, a stare of anxiety, or of grim resolution. Death from a head-wound may be so rapid that it comes on before the stricken man can even fall.

THE QUEEN has sent a cheque for £100 as a contribution to the funds of Queen Mary's Royal Naval Hospital, Southend-on-Sea. Her Majesty has expressed the hope that the excellent work of the hospital may meet with the full amount of success which it deserves.

AN INVESTIGATION OF THE ASH OF FÆCES.

By WILLIAM PARTRIDGE, F.I.C.

THE composition of fæces varies greatly in health and enormously in sickness. This is partly due to the fluctuating content of water, which in specimens examined by the author has ranged from 56 per cent. to 97 per cent. If analyses are made on the residue left on drying, some semblance to constancy in composition can be distinguished in certain directions. The fatty constituents and the mineral matter, for example, often approximate to the average figures given for them.

Little information appears to be available about the content of ash. The inorganic constituents of the average composition given by Way total 11.48 per cent. on the moisture-free specimen. *Evans' Journal* (April, 1914) puts the normal figure at 12 per cent. An author, whose name I have not got, says it ranges from 10 per cent. to 15 per cent. in normal specimens.

Several authors mention an increase in ash in catarrhal inflammation of the intestine, and a still greater increase, to an average of 25 per cent. (Evans), in chronic colitis. The diminution of ash on a meat diet and an increase on a milk diet have been noted. Eric Pritchard comments on the extraordinarily high amount of calcium found in the fæces in rickets: "As much as 25 per cent. of the dried residue of an infant's motion is often found to consist of the lime base."

The fact that the fatty constituents may differ widely in amount, suggested these to have perhaps an important influence on the content of ash, when they differed much from the normal. Variation in the content of soap cannot appreciably affect the percentage of ash, as the proportion of mineral matter in the soaps that occur in fæces (calcium and magnesium oleates, stearates, and palmitates) is about the same, when reckoned on the soap, as the proportion of normal ash reckoned on the dry fæces. An instance of this occurs in specimen No. 8 in the following table, where fatty acids to the extent of 32.9 per cent. of the dry fæces were combined with metallic bases as soaps. Yet the figure for ash is normal. The case is different with fatty acids in the free state, and with fats. When these are present in excessive quantities, they automatically reduce the percentage of ash by a process of dilution. Conversely, when these fatty constituents diminish, the ash rises in inverse proportion.

As all the specimens dealt with below were from persons who were either ill or supposed to be ill, disturbing factors are likely to be frequent. All the same, the tabulated results show the tendency of the ash figure to rise as the content of fatty acid plus neutral fat diminishes. Nevertheless, as the normal figure for fatty acid and neutral fat only averages 15 per cent., even considerable diminution in them will only raise the ash content slightly, and the factor becomes of no consequence when high ash figures are reported.

The water content bears no relation to the ash in these specimens.

In the table the moisture is, of course, reckoned on the fresh native specimen, while the totals of fatty acids and neutral fats are, like the ash, stated on the moisture-free residue.

A BROADER VIEW OF TABES DORSALIS.*

By FRANK R. STARKEY, M.D.,
Philadelphia, Pa.

THE development of our knowledge of tabes has been a matter of slow evolution since Duchenne casually alluded to the frequency of syphilis and demonstrated involvement of the posterior columns of the cord in tabes. The cause was a matter of dispute. Leyden declared chill to be the most common and probably the only cause. Duchenne was of much the same opinion, but he and Wunderlich pointed to overexertion, fatigue, and sexual excess as probable causes. Wunderlich also suggested that concussion of the spine might be a causative factor. Erb was the first to lay especial stress upon syphilis as the essential cause of tabes, and he was ably supported by Fournier among the French, and Möbius and his colleagues of Leipzig sustained him fully in this view. Möbius, with much emphasis, declared: "Without syphilis there is no tabes." Erb substantiated his opinions by a long series of tables of cases showing that syphilis was undoubtedly present in a vast majority, if not in all persons who developed tabes, but he believed it was a parasyphilitic disease due to the influence of toxins rather than the actual invasion of the cord by the syphilitic germ. As late as 1911 Oppenheim gave voice to the following: "We are by no means justified in regarding syphilis as the *conditio sine qua non* of tabes, as Brassard, Babinski, and others do. Tabes is further not a syphilitic disease in the pathologic-anatomical sense. The pathological changes have nothing in common with the well-known lesions of visceral syphilis, although Erb does not admit it. It is nevertheless conceivable that syphilitic cachexia is the result of poisonous chemical substances produced in the organism which bring about simple degeneration in certain portions of the nervous system. Those suffering from tabes seldom present any constitutional sign of syphilis." So it will be seen that at no time has there been an unanimity of opinion concerning the ætiology or pathology of tabes, and that some of our most learned neurologists and pathologists clung to views that we now believe to be entirely untenable. The discovery of the spirochæte in the cord tissues by Noguchi and Moore in 1913 placed an entirely different light on the whole matter, and it is now generally accepted that in tabes there is an actual invasion of the tissues of the cord by the spirochæte. We have, however, adhered to the histological picture of a cross section of the cord in our conception of this disease, and accepted the teachings of our forefathers, who considered it solely a systemic degeneration of the posterior columns.

We must now go beyond this very circumscribed view, for it by no means gives us an ample con-

* *New York Medical Record*, March 4th, 1916

ception of tabes in its broader sense. In view of our present knowledge of the glands of internal secretion and of the automatic and sympathetic nervous systems and the relation of the endocrinous glands thereto, we are now able to explain many mysterious phenomena of tabes which could not be accounted for solely by degeneration of the posterior columns of the cord. The nuclei of the vegetative system are so intimately associated both in the brain and the cord with those of the sensorimotor system that it is impossible to separate them. The autonomic and sympathetic nervous systems are unquestionably under the control of the glands of internal secretion, and if we study their embryonic origin we shall find that the origin of the chromaffin system, the sympathetic nervous system, and autonomic and central nervous systems is closely associated. The reproductive organs are also closely allied in this relation.

It may be well for us to pause for a moment and view the distribution of the autonomic-sympathetic system (for the sake of brevity counting them as one). The autonomic supplies the muscles of the iris, ciliary muscle, and orbital muscle (disturbance of this would account for Argyll-Robertson pupil), heart, blood vessels of the mucous membranes of the head, walls of the gut from the mouth to the descending colon, also the gastric glands, liver, and pancreas. The sympathetic, from first thoracic to second lumbar, supplies muscles, glands, and vessels of the skin, vessels of the gut from mouth to rectum, blood-vessels of the lungs, abdominal viscera, arteries, skeletal muscles, spleen, urethra, and internal generative organs. The autonomic, from second to fourth sacral, supplies arteries of rectum, anus, and external generative organs, also walls of bladder and descending colon. A lesion here would account for bladder phenomena, impotency, incontinence of urine and feces, so common in tabes. Other frequent findings in tabes which can be accounted for by disturbance of the autonomic-sympathetic system are muscular atrophy, which in tabes does not follow the course of any particular nerve, but occurs in large groups of muscles, frequently unilateral tabetic arthropathies (Charcot joint), perforating ulcer of the foot, or of the mucous membrane, occasionally with gangrene, somatic disturbances of general nutrition, disturbances of nutrition of hair, skin, and nails, and aortic disease, manifesting itself in insufficiency or aneurysm. Cardiac crises and vascular crises have been described by Pal; these crises frequently resemble angina pectoris—a feeling of oppression about the heart with arrhythmia, bradycardia, tachycardia, bradypnoea, and glycosuria, common in association with paralysis of the vagus in pituitary involvements and in tabes. Oppenheim describes a case of tabes which was marked by unilateral total paralysis of the vagus. When we remember that the vagus supplies the pharynx, larynx, lungs, heart, oesophagus, abdomen, intestines, and the fundus of the external auditory meatus we shall at once be able to account for the analgesia of the pharynx, laryngospasm, oesophagospasm, intestinal and gastric spasticity, and disturbances of the auditory tract. With the autonomic and sympathetic, like the glands of internal secretion, there is a normal equilibrium maintained in health, but in the case of the autonomic and sympathetic this balance is established by a normal antagonism between them. Stimulation of one abolishes the action of the other. The adrenal is the natural stimulator of the sympathetic, and although we cannot definitely establish it as yet, the pituitary and sexual glands are probably the natural stimulants of the autonomic, for vagotonia is conspicuous in sexual

neurasthenics and at the climacteric. Although the fibres of these two systems are so closely related that it is impossible to differentiate them anatomically, we can readily influence each system separately by the use of adrenalin for the sympathetic or pilocarpin, atropine, muscarine, or a number of other vegetable substances for the autonomic.

We may summarise the symptoms which we commonly find in disturbances of the glands of internal secretion, the autonomic-sympathetic system, and tabes, as follows: Disturbances of nutrition involving skin, hair, nails; blue, swollen, or gangrenous skin or mucous membrane; atrophy of large groups of muscles, not following the course of any particular nerve; perforating ulcer of the hand or foot; profuse sweating; neurasthenia; arrhythmia, and other disturbances of the circulatory apparatus; disturbances of respiration; glycosuria; visceral crises; analgesia of pharynx; pharyngeal, laryngeal, oesophageal, and pylorospasm; spasticity of stomach or intestines; splanchnic congestion; hyperalgesia of the abdomen; Argyll-Robertson pupil, and disturbances of the sexual organs. We must not expect to find all of these symptoms or signs of involvement of the glands of internal secretion and of the sympathetic-autonomic system in each individual case, any more than we expect to find all of the classical features of typhoid fever in every case of that disease, but a sufficient number of these signs are constantly present in all cases to prove the point at issue.

Arthropathies can be most rationally accounted for as a trophic disturbance through the sympathetic. There is absolutely nothing to differentiate microscopically the cord of a case of tabes showing arthropathies from one in which they are not present, and there is certainly nothing in common between the Charcot joint and ordinary syphilitic arthritis, nor is there the slightest pathological difference in the cord of a tabetic patient with Argyll-Robertson pupil from one with normal pupil, yet we know positively that the Argyll-Robertson pupil may be absent in tabes, and that lesion of the sympathetic will produce it. Eloesser produced Charcot joint by traumatising a segment whose posterior roots had been cut.

I believe that we should consider the treatment of tabes as separate from syphilis, not attempting to deny the syphilogenesis of the disease, and this in my opinion can be accomplished best by organotherapy. (See Starkey: "Glands of Life.") I think it is not always wise to treat the patient for syphilis, but rather, in selected cases, to treat the tabes separately. I wish to make it very clear that I do not make the slightest claim that organotherapy can cure syphilis, but tabes is not syphilis. It does, however, seem to act as a sensitiser and increases the phagocytosis or formation of antibodies, the patient's resistance is increased and he responds more promptly to antisyphilitic treatment when used in conjunction with organotherapy. I want to emphasise that in many cases of tabes where the syphilis seems to be dormant or quiescent it is better to allow the syphilis to sleep rather than to arouse it to a state of activity by antisyphilitic treatment. Such cases when treated by salvarsan or even the mercurials frequently show marked exacerbations, due to the setting free of enormous quantities of toxins or the liberation of the spirochaetes which have been encysted, and do not improve under further antisyphilitic treatment. Since the advent of salvarsan and the vigorous treatment of the primary stage of syphilis incident thereto the percentage of luetics showing early nervous involvement has been dis-

tinctly increased. Our experience seems to show that when the disease is attacked in a vigorous manner in the early stages and the secondary stage prevented or aborted, the liability to early and severe nervous phenomena is increased. It would seem that where the infection spends itself by severe secondary phenomena its virulence is attenuated and the liability to involvement of the nervous system is distinctly lessened. The German aphorism: "syphilis does not die but only sleeps," I believe to be applicable here, and when it is in a sleeping or quiescent state it is decidedly safer to let it sleep in these old cases. I have at present under my care a gentleman, 76 years of age, who contracted syphilis fifty years ago and received the rather indifferent treatment in vogue at that time. He has shown no manifestations of syphilis whatever since, until three years ago, when slight numbness of the feet with paræsthesia over part of the thoracic region and a rather marked myosis developed. He has absence of knee jerk and a two plus Wassermann. This myosis may be due to his age. He shows absolutely no other signs of syphilis, and I believe that to institute anti-syphilitic treatment in this case would be a grave error.

The question of why a very small percentage of those infected with syphilis acquire tabes, while the vast majority do not, has been puzzling one for many years and numerous very ingenious attempts to explain it have been made. I believe that it can be most rationally explained by assuming a constitutional inferiority involving primarily the glands of internal secretion, the pituitary in particular, and the consequent perversion of its secretion which is poured directly into the cerebrospinal fluid. It may be that when this gland is involved and its secretion perverted it acts as an irritant to the tissues of the cord, making them vulnerable to the invasion of the spirochæte, or again the sympathicoautonomic system, which presides over nutrition, may be originally involved in these patients and their vulnerability thus increased. This seems to be more rational than to believe that a special organism exists which creates tabes only. Certain strains of germs have been shown to have selective predilection for certain tissues, but this can be developed only by passing them through a number of individuals with a definite disease, and this particular phenomenon has never been demonstrated with the *Spirochæta pallida*. It has been shown that certain prostitutes leave numerous victims of tabes in their wake, but these instances are so rare as to be of little assistance in answering this question.

The following rather typical cases are cited not for the purpose of showing the results of treatment, but solely to illustrate the connection between the glands of internal secretion and tabes.

CASE I.—Female, æt. 45, married, one child. Family history: unimportant. Previous history: unimportant, except scarlet fever in childhood. Denies venereal disease. Seven years ago first noticed difficulty in walking in dark and numbness of feet; ataxia gradually developed until patient was unable to walk without assistance, then arthropathies (Charcot joint) developed in knees, which necessitated the use of crutches; for past three years unable to stand unassisted, compelled to use wheel chair or crutches, complains of stuffy feeling, shortness of breath. Examination: medium height, quite obese, brown hair, gray eyes, puffy face, myxœdematous appearance, unable to open eyes widely, palpebral fissure, narrow, slight external squint of right eye, skin and hair dry and harsh, subcutaneous tissue firm to pressure, entire body, especially legs, swollen in appearance but does not pit on pressure, marked hyperextension of knees making it impossible to stand, temperature 98.6°, pulse 65,

abdominal and thoracic viscera normal, Argyll-Robertson pupil, loss of knee jerk, blood pressure 120 mm. Wassermann three plus. This patient presents a typical picture of thyroid insufficiency. An orthopædic appliance for one leg was prescribed and organotherapy instituted. At the end of twenty days was able to stand and walk unassisted with hands behind back. The swollen appearance of body greatly lessened, legs so reduced in size, readjustment of brace was necessary, crutches and wheel chair entirely dispensed with.

CASE II.—Male, æt. 55, chemist. Family history: father died of diabetes, otherwise negative. Previous history: ordinary diseases of childhood, chancre twenty years ago, first noticed difficulty in walking ten years ago, a tendency to fall, lightning pains in extremities and gastric crises, diplopia then developed, was treated by ordinary methods of syphilis and received ten injections of salvarsan which caused diplopia to disappear and lessened gastric crises for a time. These pains, however, returned with usual severity. Examination: fairly well developed male, 5 feet 10 inches, dark complexion, coarse hair, prominent eyes, large lips, high cheek bones, large jaw, angular conformation of body, prominent sacral parts, large hands and feet, skin cold and clammy to touch, perspires profusely on slightest exertion, decidedly neurasthenic, tendency to muscular atrophy in large groups of muscles in arms, shoulders, back and legs, very ataxic, Argyll-Robertson pupil, knee jerk absent, examination of thorax elicits aortic insufficiency otherwise negative, dullness in percussion over entire abdomen, splanchnic congestion (evidence of vagotonia), temperature 97.5°, pulse 60, blood pressure 100 mm. Wassermann negative. I believe this patient to represent hypopituitarism and hypothyroidism secondary to hyperpituitarism and hyperthyroidism. This is further borne out by the prompt response to organotherapy. Within one week patient's temperature was normal, pulse 72, blood pressure 120 mm., and within two weeks was able to walk a chalk line without perceptible ataxia. Continued to improve under further treatment.

CASE III.—Man, æt. 45, occupation, retired, married nine years, no children. Family history: negative. Previous history: ordinary diseases of childhood, including scarlet fever and diphtheria, syphilis eighteen years ago, treated vigorously, did not develop secondary eruption, first noticed tingling sensation in feet nine years ago, which extended to legs and arms, walking became difficult one year later, and manifested difficulty in starting urine about this time. Present condition: walks with cane and assistance of nurse, decidedly ataxic, complains bitterly of lightning pains in legs, arms, and stomach, partial incontinence of urine and feces, entirely impotent. Examination: Tall, light complexion, prominent eyes, wide palpebral fissure, rather slender, delicate features, tapering fingers, very little hair on body, small bones, fine hair, skin cold and clammy, complains of cold, perspires easily, complains of choking in attempting to drink due to pharyngeal spasm, decidedly neurasthenic, pulse 70, blood pressure 90 mm., temperature 98°, Argyll-Robertson pupil, loss of knee jerk. This patient is undoubtedly one of hypopituitarism of the second classification. I saw him only twice, and was unable to make a complete study or note results of treatment.

CASE IV.—Male, æt. 60, occupation, brewer. Family history, unimportant. Previous history, ordinary diseases of childhood, typhoid fever at eighteen, denies specific infection: first noticed diplopia twelve years ago, then uncertainty in walking, especially in the dark, pains in arms, legs, and various parts of the body, treated for rheumatism, developed girdle sensation, vision became impaired six years ago, now totally blind, walks with wide base but little ataxia, however, makes very little attempt to walk unassisted. Examination: Height 5 feet 8 inches, weight 200 pounds, decidedly stout, dark complexion, coarse hair, shaggy eyebrows, heavy moustache, thick leathery skin, pudgy face, heavy lips, constantly in profuse perspiration, legs swollen and blue, skin cold and clammy to touch; examination of chest reveals small aneurysm

of ascending arch of aorta, temperature 97.8°, pulse 60, blood pressure 121 mm., knee jerk absent, areas of anaesthesia in mammary region and on inner side of thighs and legs below knees, also some perineal anaesthesia, neurasthenic, complains of insomnia, is of a positive stubborn disposition, very intractable, difficult to manage. Under organotherapy pains reduced, neurasthenia much improved, sweating lessened, insomnia disappeared. Discontinued treatment at end of ten days. I would classify this patient as thyroid insufficiency secondary to hyperthyroidism.

Many of the most troublesome symptoms of tabes can be clearly accounted for by involvement of the autonomicosympathetic system, and bearing in mind the governing influence of the glands of internal secretion over this system, the gratifying results obtained in this disease by organotherapy are easily understood.

The cardinal points in organotherapy are: first, select the glands from uncastrated animals; second, administer by intramuscular injection; third, use in combination as they occur in nature. The adrenal can be omitted in ordinary therapeutic measures, as it is represented by the pituitary. The dosage is to be worked out in each case.

There is no constant relation between the length of time tabes has existed and the amount of destruction found in the cord or severity of symptoms; neither is the severity of symptoms an always accurate index of the extent of the lesion in the cord. I have seen fulminating cases in which the patient became bed-ridden within a year after development of first subjective symptoms and other cases in which, after more than twenty years from onset of symptoms, the progress had been so inconsiderable as to but slightly inconvenience the patient. I have sections of cords showing but slight destruction of the posterior columns in which the ataxia, root symptoms, and bladder and rectal involvement were very marked early in the disease, and later improved spontaneously. The improvement in these cases may be due to sound cells taking on new functions. That an actual regeneration of cord tissue can take place is a matter of dispute, although it is certainly frequent in other nerve tissue.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE ELECTION OF DIRECT REPRESENTATIVES ON THE G.M. COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—In the *B.M.J.* for May 20th, 1916, fol. 740, there is a letter of mine on the above. I have no personal grievance, but I do protest against the policy adopted by the B.M.A. in 1906, 1911, and now about to be carried out again in 1916, by which all direct Representatives will necessarily be elected by means of the Association. The Association has its divisions covering Great Britain and Ireland, so that it is absolutely futile for anyone not nominated by the Association to have any substantial hope of success. Moreover, the enormous cost for a candidate debars men from making a real fight. In England and Wales we have over 25,000 doctors; the area extends from Land's End to Berwick-on-Tweed. To send a stamped letter to each elector would cost over £100. To canvass and to address the electorate is almost an impossible task. The policy of the Association rings the death knell of real direct representation on the G.M.C., which every fair-minded person regrets. We have been

agitating for more direct representatives, and this is only our due when we consider that the Universities have 23 on the G.M. Council, besides five appointed by the Privy Council. If the B.M.A. carries out its present policy all the representation is in its hands. The Association, numerically, is only entitled to one-half of the direct Representatives. We know that many of its members do not approve of some of its opinions and acts, especially in regard to the Insurance Act, etc. The cost to a candidate nominated by the Association need not cost 100 coppers, whilst one nominated outside the Association will cost over £100 for stamps for sending a letter to each elector. The four nominated by the Council would do what is honourable if they would ballot for two representatives and allow two to have a chance to be real direct Representatives of the profession. It has been my privilege to work for several years as Representative of Bury and Rochdale Divisions of the B.M.A. with Drs. Macdonald and Verrall, and I am confident that if it should be their good fortune to be unsuccessful, they would have a good sporting chance of being returned by the *real direct* electorate. To use the Association in the way it has been is a blotch on the escutcheon. The use of legal power in a manner subversive to any form of moral basis is not handsome nor honourable. The four representatives for England ought to be divided into four electoral areas, so that the candidates' expenses could be lessened and the views of each candidate brought before the electors. We need to have more life brought into the profession. In my opinion, if the G.M.C. had had on its Council more representatives who knew what general practice really meant, the Insurance Act in its present "derogatory form would not have been passed." The Association has stamped the Act as derogatory; what have the direct Representatives done to alter it? In my opinion, the G.M.C. ought to have acted promptly and saved the profession from the humiliating conditions involved in working the Act. I have no hesitation in stating that very many panel doctors would far rather have the old club system at 5s. per head per year than the present, which entails an enormous cost in time, in clerical work, etc., that make it often impossible to give proper care to the patients. Also the limitation as to use of certain drugs is not satisfactory for doctor nor patient. Recently four doctors, at the request of some chemists, complained that over-prescribing had been done; also that one doctor's doses were such that they were of little value. Is it not humiliating to have such criticism? All the doctors were able to explain satisfactorily the points complained of in their prescribing. Two felt that they were humiliated almost to the level of criminals.

I am, Sir, yours truly.

JNO. BROWN, M.D.

Blackpool.

May 24th, 1916.

PATENT MEDICINES AND THE BUDGET.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not want to write about the broader questions suggested by your correspondent "M.D." in your issue of May 24th, and the questions whether the State is called upon to protect the public, especially the simple and ignorant, against fraudulent quackery, and what are the prospects of far-reaching medical law reform are being constantly dealt with in your pages by much more able pens than mine. I write merely to protest against the terrible imputation which "M.D." lightly throws upon practitioners practising among the poorer class. It is, after all, now, under the panel system,

only a small minority who dispense their own drugs, and this minority is diminishing. These men are compelled often to give "advice and medicine" for a small fee. They do their duty honestly and attempt to make a correct diagnosis, and then give medicine called for in the case. The purveyor of fraudulent nostrums, on the other hand, by means of plausible, lying advertisements, makes the ignorant public believe that by a pill which usually contains only a small dose of purgative he can actually cure a score or more of different diseases, and can cure all external maladies by an ointment which is really made up entirely of coloured paraffin. The honest practitioner makes a diagnosis, or gets a second opinion to help him when he comes across a case of deadly disease which may be controlled or cured by medical or surgical science, and puts his patient in the way, often *via* the hospital, towards health and life; whilst, on the other hand, the fraudulent quack medicine seller induces vast numbers of simple people to rely upon his worthless trash until their diseases have progressed beyond the reach of medical and surgical help. The law is quite competent to stop much less harmful frauds than these, and until the attempt has failed I shall not believe in its failure to do the same in the case of quackery.

I am, Sir, yours truly,

G. P.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The writer of the letter in your last issue over the signature of "M.D." appears to be outraged at dispensing doctors selling (as he puts it) medicine which costs a few pence for 1s. 6d. or 2s. 6d. Stated in the same way, prescribing doctors sell a sheet of paper with instructions to a chemist at probably a higher charge, although the paper costs less than the dispensing doctor's medicine. Each gives advice.

I entered the profession with a prejudice against dispensing. Now that my professional career is nearly ended, I am very fully convinced that it is extreme folly—in fact, business insanity—to give prescriptions to be used indefinitely and handed about from one to another.

I am, Sir, yours truly,

AN OLD M.D.

Chelsea.

May 28th, 1916.

LEPROSY AND "KING'S EVIL."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to your comment on my evidence in the leprosy case last week, may I say that I am quite aware of the fact that leprosy and the so-called "King's evil" are not the same disease.

What I wished to convey was that in former times—as well as in the present day, as the question put to me by the judge would indicate—leprosy was frequently confounded in the popular mind with other maladies. Even now, in the West Indies, "scrofula" is one of the common names for true leprosy.

I am, Sir, yours truly,

Harley Street,

PIUN. S. ABRAHAM.

May 26th, 1916.

"SINAPIS" AND THE B.M.A.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have often wondered who "Sinapis" can be, as he will not allow the ordinary contributor to hide his head under a bushel, and yet appears weekly under the patronage of Saint Sinapis. He must be a god! At any rate, I have found much comfort, consolation and amusement from his fearless outspoken remarks. What are his views? I fancy that he is a Homœopath and believes that

"like cures like": that the B.M.A. has at some time ordered Sinapis to cure his malady and that he argues on this wise, Sinapis did me good and it may do the B.M.A. good. If my surmise be correct, it proves that he has a kindly heart. So far we have arrived at the conclusion that Sinapis is a kind god. As I turn over the pages of the MEDICAL PRESS AND CIRCULAR the B.M.A. looms large, and the ire of the god is manifest. But, dear Sir, as you know, nothing in this world is wholly bad: will you not say but one kind word?

I have read all your notes most carefully, but one thing they lack—a constructive policy. You acknowledge that the Association possesses the machinery for assisting the profession and that no other organisation exists which possesses such machinery. It is all important that we should be united at the present time, so come over and help us to obtain this desideratum. You have given us a good dose of Sinapism; now we want a little oil poured over the troubled waters. So let us look at the matter from another standpoint. Recount the good deeds of the Association, and tell us how the Association can multiply these. I can fancy you saying with Sterne:—

"Go, poor devil, and get thee gone! Why should I hurt thee? This world is surely wide enough to hold both thee and me."

I shall not criticise but suggest; because I remember "Of all the cants which are canted in this canting world, though the cants of hypocrites may be the worst, the cant of criticism is the most tormenting."

Yours,

S. J. ROSS.

Monkhams, Bedford,

May 27th, 1916.

MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Letters from old friends and new acquaintances which this correspondence is drawing to me illustrate especially what I have so often insisted upon in your pages during the past thirty years, and what I have referred to at least on numerous occasions during the same period in the *British Medical Journal*—the fact, namely, that the vast majority of members of the profession whose careers began any time after the year 1858 are almost completely ignorant of the main and minor facts of medical legislation. I believe that the proportion of your readers acquainted with this subject is greater than that of any other medical paper. You have at any rate kept the subject to the front in season and out of season during all the years. In view of the latent power which the British Medical Association might have brought out and wielded, the Association has done comparatively nothing in the promotion of Medical Law Reform; and the perfectly blameless ignorance of men who have used the *Journal* as their sole medical newspaper has been owing to the circumstances that Medical Law Reform has been greatly neglected by that paper. I shall return to this topic later and perhaps discuss earlier episodes. I would now only point out that the Report of the Select Committee on Patent Medicines has been virtually ignored by the *Journal*. The only notice it has received since its appearance was in the form of a few casual sentences in a leader of third-rate importance on another subject and under another heading. The report, with the evidence attached, I repeat, constitutes the most important document ever issued in promotion of Medical Law Reform, and it called for full exposition so that among the members there might be formed an enlightened opinion which might be focussed and brought to

bear when the occasion should arise. Not five per cent. of the members have any adequate information on the subject, and it seems to me evident that the Council is no better informed. If the Association had worked as it might towards Reform, I at any rate cannot doubt that it could have achieved this any time within the last twenty-five years. The case for Reform is overwhelming and needed only setting out with unquestionable authority to compel the Government to take notice of it. The Association drew up one or more Bills years ago, and seems to have imagined that Government would adopt one of these without any proof if its necessity. In a letter which I addressed to the *Journal* many years ago, I stated that such a procedure was certain to prove futile. I was then agitating for a Royal Commission to enquire into the whole question whilst urging that an enquiry of such a kind preliminary to a demand for legislation was imperative. I did not then know what I have since been taught, that a Select Committee would much more easily answer the purpose, and it is now evident from some utterances of the Select Committee on Patent Medicines, which I have quoted in earlier letters, that if the Association had pressed for a full enquiry into the whole subject the matter of practice by unqualified persons and fraudulent quacks would have been included in the enquiry. I do not know enough about the inner working of the British Medical Association to speak of the causes of its failure in medical politics. I do not know whether any blame attaches to any person or any party. But I am certain no blame attaches to the present Editor of the *Journal*. He is no autocrat. He gains his inspiration from the Council, and this is conveyed to him via a Committee by which he is directly controlled. The *Journal* evidently pipes a tune or holds its peace to order. I am no longer a member of the Association, but I recognise that if it fell to pieces it would be a misfortune to the profession and the public. It is the only organised body through which the profession might be able to make its voice heard. I have said before, and I repeat, that the Association has for many years been hardly anything more than a Co-operative Society for the publication of a *Journal* supplied to the members at a low price. It has in late years grown to a size two or three times bigger than is useful to the great body of members—the general practitioners. Its bulk has been swollen by introduction of great masses of literary matter not generally called for. Members who seek literary and historical reading of the kind prefer, as a rule, to choose for themselves the works they desire. One quarter of the *Journal* might be with advantage cut out and the remainder reduced by one-half. Production of the *Journal* has absorbed the greater part of the resources of the Association; it has cost, I believe, about £30,000 a year. With the doubling of the subscription plus the contribution to the Division to which the member may belong, the *Journal* is no longer cheap, and members are not likely to be long content if this is to be the sole return for their outlay.

This letter has been drawn by the question, "How about the British Medical Association?" which has been put to me and which I believe is being widely asked. In my next, with your permission, I propose to describe the attempt that was made in 1828 to provide the profession with what may be called a complete Legal Constitution, and to explain its failure.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rectory, Earlswood Common.

May 24th, 1916.

P.S.—To those of your readers who have gone through this and my previous letters it cannot be necessary for me to turn aside to examine the statements of "M.D." which appear in your issue of May 24th. "M.D.'s" letter is merely a clumsy attempt to throw dust into the eyes of uninformed people by cool suggestion of the false and suppression of the truth. When Parliament resumes its normal functions after the war nothing can prevent the bringing of the whole question of Medical Law Reformation into the sphere of practical politics. It needs no prophet to foretell that Parliament will then take in hand all such measures of social reform as shall redress the grievances and safeguard the interests of the poor, the ignorant, and the simple classes that have most claim upon the guardianship of the State. It is impossible to believe that the State will continue to tolerate the existence of the army of criminals who, for lack of simple laws, remain parasitic upon society. Among these criminals the followers of quackery in every department form the section most cunning and cynical and cruel. The report of the Select Committee is in itself more than enough to demonstrate the need for legislation, and besides the leading members of that Committee there are enough members in the House to see to it that the subject is not allowed to be put aside. It was only the war that prevented the report from being discussed immediately after its appearance.

May 27th.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, MAY 26TH, 1916.

The Ex-President, DR. E. CAUTLEY, in the Chair.

DEMONSTRATION OF CASES AND SPECIMENS.

DR. CAUTLEY showed two cases of optic neuritis (? cerebral tumour). The first case, a boy, aged 6 years 8 months, attended as an out-patient at the Belgrave Hospital for Children on April 17th, under Dr. Prentice, who admitted him the following week with these notes:—

"April 16.—Headache for two weeks. Wakes up screaming at night. Anorexia, furred tongue, offensive breath, (?) vomiting, B.O.

"April 17th.—Not so well; headache, retching, drowsiness. Arm reflex greater on the left than right side; normal abdominal reflexes; knee-jerks equal and brisk. Gait unaffected. Optic discs swollen, and hæmorrhage on the left disc. He vomited during the afternoon, but did not complain of headache."

Since being in hospital he has not suffered from headache or vomiting. Mr. Bishop Harman's report on eyes (May 9th): "Bilateral papillitis, 1.5D. elevation. Fine interstitial hæmorrhages at left disc, no exudation. No disorder of fixation." There was no albuminuria. The gait was a little stiff.

The second case was a girl, æt. 11, admitted to Belgrave Hospital on April 27. One month before she had two fits. Since then she had had almost constant headache and vomiting, the result of the headaches. On April 26th she had another fit. She was a strong, high-coloured, healthy-looking girl. Her abdominal reflexes were practically absent; deep reflexes depressed, the left rather more marked than right; plantar reflexes absent. Her head was tilted somewhat towards the right shoulder, which was a little raised. Gait somewhat unsteady,

(2) cerebellar, and she tended to fall backwards and to the left. Her left side was a little weaker than the right and showed slight inco-ordination, probably sensory; and for the same reason the left movements were clumsy. The eyes showed nystagmoid movements, lateral and rotatory, and slight left convergent squint. Perhaps there was a little weakness of the left facial nerve; and there was double optic neuritis.

Mr. Bishop Harman's report (May 9th): "Nystagmus on extreme duction, tendency to left convergent squint; well-marked papillitis in each eye, about 2D. elevation, a trifle more on the right side; no hæmorrhages or exudation, slight silkiness of right macular region."

Since being in hospital no special symptoms had been noted and she had not suffered from headache or vomiting.

Dr. CAUTLEY also showed a case of infantilism in a boy, aged 6 years 8 months, sixth child. He was said to have been a puny babe, but to have grown up to three months of age. At the age of 9 months he only weighed $4\frac{1}{2}$ lbs., and from 13 to 18 months of age he remained stationary at 6 lbs. 1 oz. He was entirely breast-fed for one and a half years, and partially so for another six months. Proprietary foods were given up to the age of $4\frac{1}{2}$ years, and since then he had had ordinary diet. His mother suckled her previous baby for eighteen months, up to her confinement with this child. During the first year of life he was remarkably somnolent; and at the age of three years he had diphtheria. At times he was troubled with constipation, and occasionally with cramps in the hands and feet. He had had no such troubles during the two months he had been under observation.

Condition on May 18th: Height, $26\frac{1}{2}$ in.; weight, 16 lb. 14 oz.; head, 17 in. He was pot-bellied, markedly rachitic, and the liver had dropped well below the costal margin. There were enlarged tonsils, adenoids, and moderate adenitis. The skin was elastic and complexion rather dull. He spoke fairly clearly, and mentally appeared about four to five years of age. He had twenty good teeth, the first having been cut at the age of two years. His appetite was poor.

On April 22nd he developed pertussis. This induced convulsions, once on April 24th and four times on April 25th, and was followed by general bronchitis. On admission on March 25th he weighed 15 lb. 12 oz., and on April 20th he had gained 28 oz. Since then the pertussis and bronchitis had caused loss of weight. The Wassermann reaction was negative.

There appeared no special cause for his backward development, beyond malnutrition and unsuitable feeding during early life. He had been taking polyglandin and improved, but the improvement may have been due to food and nursing.

Dr. W. MITCHELL SMITH showed a case of gigantism in a girl, aged 12 years 9 months.

Family history: Patient was the seventh of ten pregnancies; two miscarriages; five died at or soon after birth; three living and well: brother, aged 20 years, height 5 ft. $9\frac{1}{2}$ in., weight 16 st.; a brother, aged 11 years, normal; and present case. Father suffers from diabetes; once 17 st., now 14 st. Mother healthy. Maternal grandmother reputed to be 32 st. at time of her death.

Present condition: Height, 5 ft. $4\frac{1}{2}$ in.; weight, 17 st. 7 lb. Very obese, with equal distribution of fat; large framework, especially across the hips. Pubic hirsuties. Menstruating regularly since last Christmas. Blood-pressure, 125 mm. Hg.; urine normal; optic discs normal. Mentality normal for a girl of her age (Standard VII.); excellent memory, placid disposition, gross eater.

Skiagram of sella turcica showed that (1) it was very well developed for a girl of her age; (2) there was no erosion of anterior or posterior part to indicate a tumour of any size.

Dr. J. WALTER CARR showed a case of juvenile general paralysis in a boy, æt. 8. There was nothing in the family history to suggest syphilis, and the patient did not present any of the stigmata of the disease. He had not had any previous illness of importance. For about six months his walk had been getting increasingly jerky, and he had sometimes fallen down. For the last three months his pupils had been noticed to be unequal. Recently his speech had been getting indistinct and mumbling. Formerly he was rather bright at school, but of late had ceased to make any progress; had been unable to write, and had lost his memory. He had not had any convulsions. He was a healthy-looking, rather excessively stout boy. He showed marked mental impairment, with distinct delusions of exaltation—for instance, he talks of having knocked down a policeman and killed two Germans. He had incontinence of urine and often of fæces also. The left pupil was larger than the right and reacted very sluggishly to light; the right pupil reacted normally. The left optic disc was very considerably paler than the right. He had a distinctly spastic gait, with double ankle clonus and exaggerated knee-jerks. The triceps and supinator jerks were also increased. It was not possible to be sure whether the plantar reflexes are flexor or extensor. There was no ataxy. Wassermann reaction of blood positive.

Mr. A. S. BLUNDELL BANKART showed a case of hemi-hypertrophy—partly crossed, in a boy, æt. 6. Asymmetry of face and limbs was noticed soon after birth. The condition had remained stationary, except in so far as the child had grown. The right side of the face, right half of the tongue, right thigh, and right leg were decidedly larger than the corresponding parts on the left side. The left forearm was decidedly, and the left arm was slightly larger than the right forearm and arm respectively. Skiagrams of the forearms and legs showed that the bones on the enlarged side are slightly thicker than those of the smaller side (?). There was no increase in length. The left testicle was slightly larger than the right.

Dr. C. O. HAWTHORNE showed a case of double optic neuritis in a boy, æt. 9, without other evidence of intracranial or nervous disease, or of disease in the thoracic or abdominal viscera. Some degree of anæmia, but by no means extreme, and Wassermann reaction negative. Had been under observation in hospital for fourteen days, and except for some headache on first day had seemed quite well and happy. Acuity of vision, 6/5 each eye. The history was of occasional attacks of headache commencing eight months ago, sometimes very severe, and in recent weeks often accompanied by vomiting. No admitted violence to the skull or of illness other than the above. There was a history of "consumption" in the mother's family and of "fits" in that of the father; a sister had a "tubercular knee."

Mr. E. D. D. DAVIS showed a case of ulceration of the soft palate in a girl æt. 13 years, who had been sent to Charing Cross Hospital by Dr. J. D. Rolleston with the history that she had been admitted to the Fever Hospital for diphtheria on April 14. One week before admission to the Fever Hospital she complained of sore throat but was otherwise quite well. Cultures of the fauces showed no diphtheria bacilli and direct smears showed no Vincent's organisms.

When seen by Mr. Davis on May 19th there was a large irregular ulcer involving the left half of the uvula, soft palate, and left pillar of the fauces, with considerable loss of the left half of the palate.

The ulceration was atypical of lupus, tubercle, or syphilis, but there was no other lesion of the nose, pharynx, larynx, or ear. Wassermann's reaction was positive.

Mr. E. D. D. DAVIS also showed a case of lupus of the hard palate and gums for comparison with the above.

Dr. CAUTLEY (for Dr. P. Hamill) showed a case of recurrent jaundice. The patient, a girl, æt. 13, had been under observation since November, 1914, suffering from recurrent attacks of jaundice. From then up to the present time she had not been entirely free from pigmentation. During the exacerbations bile was present in the urine, the fæces were clay-coloured, and the liver was enlarged. In the intervals her general health was good. Since January, 1916, the spleen had begun to enlarge, and had extended more than 1 in. below the costal margin. During an exacerbation the blood count was found to be: Red blood cells, 3,78 million; white blood cells, 10,800 per cubic millimetre; hæmoglobin, 70 per cent.; colour index, 0.9 per cent. Differential count: Polymorphonuclears, 52 per cent., total number 5,620; lymphocytes, 45 per cent., total number 4,860; eosinophiles, 1 per cent. total number 100; basophiles, 2 per cent., total number 220. Very slight anisocytosis and poikilocytosis, no nucleated red cells seen. Corpuscular fragility normal. Loewi's pancreatic reaction was negative.

Dr. CAUTLEY (for Dr. P. Hamill) also showed a case of unilateral enlargement of the tongue. The patient, a girl, æt. 5, was brought to hospital with unilateral enlargement of the tongue. It was with difficulty that the tongue could be retained in the mouth. The enlargement appeared to affect the right side only, and involved the floor of the mouth. The papillæ were enlarged but did not resemble the minute vesicles commonly seen in cases of lymphangiectasis. Skiagrams did not reveal any corresponding hemihypertrophy of the cranial bones.

Mr. PAUL BERNARD ROTH showed a case of congenital defect of the left ulna in a girl, æt. 9, which was described in the *Lancet*, May 23rd, 1914.

Dr. J. LAWSON DICK read a paper on The Teeth in Rickets.

And Dr. ERIC PRITCHARD read a paper on The Rational Treatment of Rickets, with illustrative case.

SPECIAL REPORTS.

GENERAL MEDICAL COUNCIL.

ONE HUNDRED AND THIRD SESSION.

FIRST DAY, TUESDAY, MAY 23RD, 1916.

Sir DONALD MACALISTER, President, in the Chair.

The ACTING REGISTRAR having called the roll, the PRESIDENT intimated that he had received a letter from Sir Isambard Owen stating that he would be unable to be present during the session on account of war business. The President understood that Dr. David Hepburn would also be unable to be present owing to his military duties.

Mr. Littlejohn was then introduced by Mr. HODSDON.

The official intimation of Mr. Littlejohn's appointment as representative of the University of Edinburgh had been read on November 2nd, 1915.

The official notification of the appointment of Dr. Johnson Symington as representative of the Queen's University of Belfast for three years from April 12th, 1916, was read.

Dr. Symington was introduced by Dr. LITTLE.

Also that of Professor Andrew Francis Dixon, M.B.,

Sc.D., as representative of the University of Dublin for five years from May 13th, 1916.

Professor Dixon was introduced by Dr. LITTLE.

The PRESIDENT delivered the following address:—

GENTLEMEN,—The Council meets to-day in its new Chamber, and enters into complete occupation of the building erected for its accommodation under the supervision of the Site Committee. To that body, to the architect, Mr. Frere, to the builders, Messrs. Chinchin and their craftsmen, to the office staff, and to all who have helped forward the work of construction, equipment, and arrangement, under conditions of exceptional difficulty, I would, in the Council's name, express our grateful acknowledgments. Members and the public will find, I hope, that the new offices enable us to transact business in circumstances of greater quiet and comfort than were possible in Oxford Street. Considerations of economy have made us postpone for the present some desirable improvements in matters of furnishing and the like. The essentials have been provided, however, and the rest can be added as times improve. Meanwhile, it is satisfactory to know that the expenditure on the building and its contents has been met from the proceeds of the sale of the Oxford Street premises and from surplus funds in the hands of the Council and its branches. The building will thus be free from debt, and at the same time the income hitherto derived from the Council's property, on the old site, will be unimpaired. The new offices will, I am persuaded, prove in the end to be thriftier, as well as handier, than the old.

Our late President, Sir William Turner, who took a warm interest in the transfer, has not lived to see it completed. His death in February last deprived us of a wise and experienced counsellor, and his University of a great administrator, honoured alike for his scientific eminence and for his sterling character. In remembrance of his long association with the Council, I have ventured to place his bust in this Chamber. It is the original model for the marble bequeathed to the Anatomical Museum at Edinburgh. Through the courtesy of the sculptor, Mr. Herbert Hampton, I have been enabled to acquire it; and I now offer it for your acceptance as a memorial of my distinguished predecessor.

We have also to lament the loss of our friend and colleague, Sir Charles Bent Ball, who died in the midst of his many activities two months ago. His strong good sense, his professional knowledge and skill, and his genial warmth of manner, gained for him an influential position here as elsewhere. We shall miss him greatly, both in the Council and in the Committees, whose work he guided with real devotion.

Sir William Whitla retires on the completion of his term of office as the representative of the Queen's University of Belfast. His great erudition and practical knowledge in the department of pharmacology and therapeutics were freely placed at the service of the Pharmacopœia Committee. His colleagues and the editors were constantly indebted to him for willing and able help in the preparation of the new *Pharmacopœia*.

In his place the Queen's University has appointed Professor Symington. As successor to Sir Charles Ball, the University of Dublin sends us Professor Dixon. The addition of these distinguished anatomists to those who are already valued members of the Council will ensure that the importance of anatomy as a branch of medical education will not be overlooked. Dr. Harvey Littlejohn, whose appointment in place of Sir Thomas Fraser I intimated in November, takes his seat now. To him, and to the other new members, I desire to offer not only an official but a personal welcome. I am privileged to call them friends as well as colleagues.

At the end of last year, our General Registrar, who is still on military service, was promoted to the rank of lieutenant-colonel.

The necessary demands of the Services for qualified medical officers continue to put a severe strain on the resources of the profession. The Central and Local Committees, which have now been established in the three Kingdoms, and recognised for recruiting purposes

by the military authorities, are actively engaged in endeavouring to meet these demands, and at the same time to leave a fair provision for the medical needs of the civil population. The task is not easy. It calls for much careful consideration of individual persons, places, and circumstances. This could hardly be given under any general scheme of conscription, or by any but professional committees in touch with practitioners throughout the country. The value of the work already done by these committees is acknowledged by the War Office and the Admiralty. The greater the support and confidence extended to them by the profession, the better they will be able to carry through their important operations for the good of all.

It had been expected that in 1915, the first complete year since the war began, the number of practitioners added to the *Register*, and available for military or civil work, would show a perceptible decrease. The expectation would probably have been realised but for the decision to recall from the combatant ranks medical students of the senior years, and but for the establishment of reciprocity with the Dominions and with Belgium. In the result it came out that the number of registrations in 1915 was 1,526, or 354 in excess of the average (1,172) for the preceding five years. Of the whole number 181 appear in the *Colonial List* and 88 in the *Foreign List*.

The question of maintaining, in this and in future years, a supply of newly-qualified practitioners, sufficient for the needs of the country continues to engage the attention of the military authorities and of the Council. The calling-up of junior medical students, under the successive systems of recruiting, has undoubtedly given rise to some anxiety. Enquiries were accordingly made, at the instance of Lord Derby, as Director-General of Recruiting, in order to ascertain the facts of the situation. From returns obtained by the Council last January, it appeared that the number of students who during 1915 began medical study in the various professional schools and teaching institutions was 1,935. The number of first-year women students was 456. The number of second-year students was 1,020. The average annual entry of first-year students registered during the preceding five years was 1,441. In 1915 there were thus nearly 500 first-year medical students in excess of the average annual number registered in the preceding five years.

At the beginning of the present year the number of first-year students in actual attendance on instruction at medical schools (apart from teaching institutions) was ascertained to be 1,626.

The expected depletion of students, as compared with normal years, had thus been more than compensated by new entries, and if things remained as they were, the position four years hence would not be unsatisfactory. It was thought advisable, however, to recommend that exemption from military service, already conceded to fourth-year and fifth-year students, should be extended to third-year students, who showed their proficiency in the earlier subjects of the curriculum by passing a third-year professional examination in March or April, at the end of the winter session. An Order to this effect was accordingly issued from the War Office. Lord Derby then asked the Executive Committee to appoint a small committee, including two representatives nominated respectively by the President of the Board of Education and the Secretary for Scotland, for the purpose of watching the general situation as regards Great Britain, and reporting upon it to him as Director-General of Recruiting. In view of the fact that under the attestation and the compulsory systems, many of the medical students of 1915 would by April have been called from their studies, Lord Derby further requested that returns should be obtained of the numbers, belonging to each of the five years, who were in actual attendance on professional courses of instruction at the beginning of the present summer session. The replies to my inquiries on this head, for which I have to thank the authorities of the schools of medicine and teaching institutions, were returnable on May 18. They are not yet complete, and they have not been fully analysed. But the Council will be interested to learn that so far as they go they give the following results:—

Students still pursuing their professional studies in May, 1916:—

First year	1,800
Second year	950
Third year and fourth year	1,750
Final year	950

The expected depletion is most marked in the third-year and fourth-year group. Owing to the Order I have mentioned many third-year students are reckoned with fourth-year students for recruiting purposes, and the group cannot readily be divided. Your committee propose to call Lord Derby's attention to this group, as its present depleted condition indicates that a shortage of newly qualified practitioners may be expected by the end of the year 1918.

The representations made to the Government on your behalf, respecting the Scottish Midwives Bill, were effective. The Bill, which was properly regarded as an emergency measure, became law on December 23, 1915. The Scottish Board has since been duly constituted, and the first set of rules for the enrolment of midwives has, after submission to the Executive Committee, been approved by his Majesty in Council.

Revised rules, framed by the Central Midwives Board under the English Act with a view to the better training and supervision of certified midwives, will be submitted to the English Branch Council during the present session. They indicate that the policy of the Central Board is progressive, and that its aim is to increase the efficiency of midwives. In the present emergency the responsibilities of these women must necessarily become greater, and it is the more imperative that the State and the profession should take steps to ensure their entire fitness. That some practitioners have not yet realised their duty with respect to the operations of women, who are *not* certified as fit to attend mothers in childbirth, is strongly suggested by cases brought before you at the last and at the present session. The Council will doubtless be prepared to consider whether the time has not come to issue a special warning notice on this subject.

In Scotland an important legal precedent has been established by a decision, on appeal, of the Court of Session. A limited company carries on in Edinburgh an objectionable form of unqualified practice under the style of the "Dr. Temple Company." The Royal College of Physicians, with Dr. Norman Walker its Treasurer, has succeeded in obtaining a perpetual interdict against the company, restraining it from using the word "Dr." and so pretending to the public that it possessed some medical title to practise. The Royal College has thus vindicated its claim to intervene for the protection of the people of Edinburgh against a gross form of imposition. Company law and administration in England have hitherto failed to check similar abuses. The civic spirit of the Royal College merits our cordial recognition, and its success may well encourage other corporations to re-examine their powers in respect of the medical interests of the public.

In another Scottish court, a pretender to medical qualifications, who attempted to obtain money by falsely assuming a medical title, has been sentenced to three months' imprisonment, apparently without the option of the fine for mere false assumption provided in Section 40 of the Medical Act, 1858. This also may prove to be a useful precedent in extension of the meagre safeguards of the statute.

Several of the penal cases you will have to consider this week relate to practitioners who have been tried and convicted elsewhere. It is for the Council to decide whether these practitioners should be allowed to remain on the *Medical Register*.

The exigencies of the war have induced certain of the Canadian provinces to reconsider their position with regard to Imperial reciprocity. In November I reported that Ontario and Saskatchewan had ranged themselves with the Eastern provinces. Now I report that legislation for the establishment of reciprocal relations has been effected in Manitoba and is proceeding in British Columbia. The Province of Alberta alone remains outside the movement. It has expressed a desire for reciprocity, but so far we have not learned that it has taken the necessary action. When it does,

the Dominion of Canada will, province by province, have fulfilled the conditions laid down in the Medical Act, 1886. There will then be no obstacle to the application of that Act by His Majesty to Canada as a whole, and to our recognition, for purposes of registration here, of the Diploma in Medicine, Surgery and midwifery, granted after examination by the Canada Medical Council. The whole problem of Canadian qualifications would thus at once receive a satisfactory simplification.

The Empire of Japan, whose University degrees in medicine have long been registrable, has now decreed that in October, 1916, the new law on medical practice, intimated to the Council ten years ago, will come into effective operation. The Japanese authorities will then be able to guarantee that the degree of Bachelor of Medicine, granted by specified medical colleges under Government direction or supervision, will represent a qualification not inferior to the corresponding University degree. The Executive Committee will consider the question of adding this college degree, granted under the new conditions, to the list of qualifications registrable in the *Foreign List*.

Reports may be expected from the respective committees on the teaching of medical ethics, the revision of the dental curriculum, and other topics of interest.

A reference to the minutes of the Executive Committee will show how numerous and important are the matters with which it has had to deal since last session. Medical and dental legislation throughout the Empire has given rise to questions of policy and practice on which the advice of the Committee has been sought by the Privy Council, the Foreign Office, the India Office, and the Colonial Office. In pursuance of the powers delegated to the Committee, such advice has been given, and gratefully accepted by the Departments of the State.

Moved by Dr. LITTLE, seconded by Dr. NORMAN MOORE, and carried by acclamation: "That the President be thanked for his address, and requested to let it be printed in the minutes."

Moved by the CHAIRMAN of the Business Committee, seconded by Sir HENRY MORRIS, and agreed to: "That the Council do adjourn at 4 p.m. to-day to enable certain committees to meet for the completion of their reports."

Moved by the CHAIRMAN of the Business Committee, seconded by Sir HENRY MORRIS, and agreed to "That the yearly tables dealing with examinations be received and entered in the minutes, and be referred to the Examination Committee for its consideration."

The Council proceeded to the election of the Executive Committee, Dr. Dixon and Dr. Symington acting as scrutineers.

It was agreed that the following be the members of the various committees:—

• Business Committee.—Dr. Norman Moore (Chairman), the President, Sir Henry Morris, Dr. Norman Walker, Dr. Little.

Pharmacopœia Committee.—The President (Chairman), Dr. Norman Moore, Sir George Philipson, Dr. Caton, Dr. Barrs, Dr. Cash, Dr. Norman Walker, Sir John Moore, Dr. Little.

Finance Committee.—Mr. Tomes (Chairman), the President, Sir Henry Morris, Mr. Hodsdon, Dr. Little.

Dental Committee.—The President (Chairman), Sir Henry Morris, Mr. Tomes, Mr. Hodsdon, Sir Arthur Chance.

Dental Education and Examination Committee.—Mr. Tomes (Chairman), The President, Sir Henry Morris, Mr. Hodsdon, Dr. Knox, Sir Arthur Chance, Dr. Symington.

Students Registration Committee.—Dr. Norman Moore (Chairman), The President, Dr. Langley Browne, Dr. Mackay, Dr. Norman Walker, Sir Bertram Windle, Dr. Kidd.

The Council proceeded to the election of the Penal Cases Committee, Sir Arthur Chance and Dr. Littlejohn acting as scrutineers.

On motion from the CHAIR, seconded by the CHAIR-

MAN of the Business Committee, it was agreed: "That the following report from the Executive Committee made pursuant to Standing Order VII., 19, be received and entered in the Minutes:—

REPORT.

On November 2nd, 1915, the Executive Committee reported that Part II. of the Medical Act (1886) having been applied by an Order of His Majesty in Council dated June 10th, 1915, to the Province of Saskatchewan (see Minutes, 1915, pp. 150-151), the Committee had considered the conditions under which Medical Qualifications granted in the Province should be recognised for registration in the *Colonial List* of the *Medical Register* of the United Kingdom, and that in the event of information being received that the arrangements for reciprocity with the Province of Saskatchewan had been satisfactorily completed, and that a course of professional study extending over five years had been instituted in the Province, the President had been empowered on behalf of the Executive Committee to direct the Registrar to register any person who holds the Licence of the College of Physicians and Surgeons of Saskatchewan, granted after examination in Medicine, Surgery and Midwifery, together with the Licence to practise in the Province, in the *Colonial List* of the *Medical Register*, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886.

The desired information as to the adoption of the five-years course in 1915 having been received, the President, in virtue of the powers conferred upon him, directed the Acting Registrar, on April 5th, 1916, to register any person who produced the Licence of the College of Physicians and Surgeons of Saskatchewan, and who satisfied the prescribed conditions.

Dr. MAGENNIS asked the President the following question, of which he had given notice:—"By what Statutory Authority does the Council pay the Deputy appointed to attend and be present on behalf of the General Medical Council at the professional examinations held by the Apothecaries' Hall, Ireland, for the purpose set forth in Section 18 of the Medical Act, 1858, and to report to the Council the general character of such examinations?"

The PRESIDENT answered that the Council had acted under the authority conferred upon it by Section 13 of the Medical Act, 1858, which provided that: "All monies payable to the respective Councils shall be paid to the Treasurers of such Councils respectively, and shall be applied to defray the expenses of carrying this Act into execution," and Section 18 of the same Act which provided that "The several colleges and bodies in the United Kingdom mentioned in Schedule (A.) to this Act shall from time to time, when required by the General Council, furnish such Council with such information as they may require as to the courses of study and examinations to be gone through in order to obtain the respective qualifications mentioned in Schedule (A.) to this Act, and the ages at which such courses of study and examination are required to be gone through, and such qualifications are conferred, and generally as to the requisites for obtaining such qualifications; and any member or members of the General Council, or any person or persons deputed for this purpose by such Council, or by any branch Council, may attend and be present at any such examinations."

The President announced that the following had been elected members of the Penal Cases Committee:—The President, *ex officio*, Dr. Saundby, Mr. Tomes, Dr. Norman Walker, Dr. Little, and that the following had been elected members of the Executive Committee: The President, *ex officio*, Dr. Norman Moore, Sir Henry Morris, Mr. Tomes, Dr. Langley Browne, Mr. Hodsdon, Dr. Norman Walker, Sir John Moore, Sir Arthur Chance.

Strangers then, by direction from the Chair, withdrew in order that the Council might consider certain matters of business *in camera*.

The Council subsequently adjourned.

SECOND DAY, WEDNESDAY, MAY 24TH, 1916.

The President, Sir DONALD MACALISTER, in the Chair.

The minutes of the last meeting were taken as read, and confirmed.

The Council proceeded to the consideration adjourned from November 4th, 1915, of the case of Herbert Midgley Reeve, registered as of 1 Bourne-mouth Park Road, Southend-on-Sea, M.R.C.S.Eng. 1899, L.R.C.P.Lond. 1899, M.B.U.Lond. 1899, who had been summoned to appear before the Council on the following charge:—

“That being a registered medical practitioner you knowingly enabled one Mary Ann Preece, whose name had been removed by the Central Midwives Board from the roll of midwives, to practise as a midwife in contravention of the provisions of the Midwives Act, 1902, as if the said Mary Ann Preece were duly certified under the said Act.

“And that in relation thereto you have been guilty of infamous conduct in a professional respect.”
The complainants were the Central Midwives Board.

At the conclusion of the proceedings the PRESIDENT announced the decision of the Council. . . The Council takes a very grave view of the action of a medical practitioner who “covers” the practice of unqualified or uncertified women, under whatever pretext they practise midwifery or otherwise attend and treat women in labour. But in order to give you an opportunity of reconsidering your position in relation to this matter, the Council has postponed judgment in your case till the next Session, in May, of which you will receive due notice. You will then be required to attend, and to produce testimony from your professional brethren as to your character and conduct in the interval.

Mr. Reeve attended in answer to his summons, accompanied by Mr. W. V. Reeve, his solicitor.

The Central Midwives Board, the complainants, were represented by Mr. Julius Bertram, their solicitor.

Sir Francis Champneys, President of the Central Midwives Board, withdrew, and the PRESIDENT announced that he would take no part in the proceedings.

The PRESIDENT having referred to the finding of the Council at the previous hearing, Mr. W. V. REEVE read testimonials referring to Mr. Herbert Midgley Reeve's conduct in the interval, from Mr. James B. Maxwell, Mr. John F. Walker, M.B., Dr. C. Grant Pugh, Medical Officer of Health of the Borough of Southend-on-Sea, and Councillor H. William Cooper, of the Borough Insurance Committee.

Mr. BERTRAM, on behalf of the complainants, expressed his gratification at the nature of the testimonials produced, and did not desire to address the Council on behalf of the complainants.

Mr. W. V. REEVE then briefly addressed the Council on behalf of his client.

At a suggestion from the CHAIR, Mr. H. MIDGLEY REEVE expressed his regret for his past conduct, and gave the Council an undertaking as to his conduct in the future.

Strangers having been re-admitted after the Council had deliberated *in camera*, the PRESIDENT announced its judgment as follows:—

Mr. Reeve: I have already informed you on behalf of the Council of the grave view it takes of the nature of the offence, specified in the charge, which had been proved against you; but having regard to your assurances as to your conduct in the future, the Council has not seen fit to direct the Registrar to erase your name from the *Medical Register*.

The Council proceeded to the consideration of the case of Frederick Robinson, registered as of 96 Clough Road, Masbro, Rotherham, L.R.C.P.Edin. 1880, who had been summoned to appear before the Council on the following charge:—

“That being a registered medical practitioner you by your assistance knowingly enabled a Mrs. F., a woman not certified under the Midwives Act, 1902, to

attend women in childbirth under cover or pretence that such women were attended or to be attended by you or by her under your direction, thereby enabling the said Mrs. F. in contravention of the said Act to practise as if she were certified thereunder.

“And that in relation thereto you have been guilty of infamous conduct in a professional respect.”

The complainants were the Central Midwives Board.

Mr. Frederick Robinson was not present in answer to his notice, nor was he represented by counsel or solicitor.

The solicitor read a telegram which he had received that day from Mr. Robinson declining to attend.

The Central Midwives Board, the complainants, were represented by Mr. Julius Bertram, their solicitor.

Sir Francis Champneys, President of the Central Midwives Board, again withdrew, and the PRESIDENT announced that he would take no part in the proceedings.

The Council's Solicitor having read the notice, Mr. BERTRAM addressed the Council on behalf of the complainants, and then called Mr. George William Duncan, the Secretary of the Central Midwives Board, as a witness, and examined him as to the accuracy of his declaration. No member of the Council desired to put any question to Mr. Duncan. He answered a question put to him by the Legal Assessor. Mr. Bertram put in six certificates of conviction of Mrs. F. referred to in Mr. Duncan's declaration; he next called Mr. Charles Lee des Forges, the Town Clerk of the Borough of Rotherham, and examined him as to the working of the Midwives Act in Rotherham, and as to his knowledge of Mrs. F. No member of the Council desired to put any question to Mr. des Forges.

Mr. BERTRAM then called Mrs. Caroline Eyre as a witness, and examined her as to the truth of her declaration. She answered questions put to her from the Chair, and by the Legal Assessor. Mr. Bertram called in succession Mrs. Annie Johnson, Mrs. Rose Hamilton, Mrs. Mabel Rosine Searson, Mrs. Florence Pearce, Mrs. Emily Smithurst, and examined them as to the truth of their declarations. They all answered questions put to them from the Chair.

Mr. BERTRAM also called Mrs. Grace Reed and Mrs. Amy Worth, who had not made declarations, and examined them as witnesses. Mrs. Worth also answered a question put from the Chair.

He called also Mrs. Mary Jane MacGrevy, certified midwife, and examined her as a witness, and then Miss Mary Stewart, Inspector of Midwives and Health Visitor, as a witness, and examined her as to the notifications of birth in the confinements of certain of the previous witnesses. She answered questions put from the Chair and by members of the Council through the Chair.

In the absence of Mr. Frederick Robinson, the Legal Assessor placed before the Council the letters which Mr. Robinson had written in answer to the complaint and the charge, dated March 25th, 1916, May 13th, 1916, and May 22nd, 1916.

He also read a letter dated May 18th, 1916, requesting that the case might be postponed, and a telegram dated May 22nd, 1916, withdrawing the request. The telegram read by the Solicitor at the commencement of the proceedings was also put in. This closed the case. Mr. Bertram did not address the Council in reply.

The Council deliberated on the case *in camera*.

Strangers having been re-admitted, the PRESIDENT announced the judgment of the Council as follows:—

I have to announce that the Council have judged Frederick Robinson to have been guilty of infamous conduct in a professional respect, and have directed the Acting Registrar to erase from the *Medical Register* the name of Frederick Robinson.

The Council proceeded to the consideration of the case of Kenneth Ram Gujral Shaw, registered as care of Thomas Cook and Son, Ludgate Circus, E.C., M.B., Ch.B. 1912, U.Edin., who had been summoned

to appear before the Council on the following charge:—

"That being a registered medical practitioner you were convicted of the following misdemeanours, viz. :—

"(1) On September 17th, 1915, at the Thames Police Court, of being drunk and disorderly, in respect of which offence you were bound over in the sum of 60s. to be of good behaviour for six months.

"(2) On September 21st, 1915, at the County of London Sessions, of exposing your person, in respect of which offence you were on October 12th, 1915, bound over in the sum of £5 to appear for judgment if called upon within twelve months."

Mr. Shaw was called, but did not answer to his name, nor was he represented by counsel or solicitor.

The ACTING REGISTRAR having read the notice, the Council's Solicitor laid the facts of the case before the Council.

He read a letter from the Commissioners of Police of the Metropolis, establishing the identity of the convicted person who was described as Kenneth Shaw, with the registered practitioner named Kenneth Ram Gujral Shaw. He proved the service of the notice of inquiry by registered letter to Mr. Shaw's registered address, and read a letter, supplementary to the notice, which he had written to Mr. Shaw as to further evidence which he proposed to place before the Council.

The Council's Solicitor put in the two certified copies of the convictions. He read reports from the office of the chief Commissioner of Police to the Acting Registrar, notifying the convictions.

He called Mr. Carol Naish O'Sullivan, a registered medical practitioner, for whom Mr. Shaw had acted as *locum tenens* at the time of his first conviction, as a witness, and examined him as to Mr. Shaw's conduct while in his service.

Mr. O'Sullivan answered questions from the Chair, and by members of the Council through the Chair.

The Council's Solicitor called Miss Gertrude Fleming, governess in Mr. O'Sullivan's service, and examined her as a witness. No member of the Council desired to put any questions to Miss Fleming.

This closed the case.

After the Council had deliberated *in camera* and strangers had been re-admitted, the PRESIDENT announced the judgment of the Council as follows:—

I have to announce that, Mr. Kenneth Ram Gujral Shaw having been proved to have been convicted of the misdemeanours alleged against him in the notice of inquiry, the Acting Registrar has been directed to erase his name from the *Medical Register*.

The Council proceeded to the consideration of the case of Daniel Evans Powell, registered as of 101 High Street, Tooting, S.W., M.B., C.M., 1894, U.Glasg., who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you by your assistance knowingly enabled one J. W., a woman not certified under the Midwives Act, 1902, to attend women in childbirth under cover or pretence that such women were attended or to be attended by you or by her under your direction, thereby enabling the said J. W. in contravention of the said Act to practise as if she were certified thereunder.

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Central Midwives Board.

Mr. Powell attended in answer to his notice, accompanied by Mr. J. A. C. Keeves, his counsel (acting for Mr. Curtis Bennett, who had been called away), instructed by Messrs. W. Butcher and Sons, solicitors.

The Central Midwives Board, the complainants, were represented by Mr. Julius Bertram, their solicitor.

Sir Francis Champneys, President of the Central Midwives Board, withdrew, and the PRESIDENT announced that he would take no part in the proceedings.

The Council's Solicitor having read the notice, Mr. BERTRAM, before opening his case, sought leave to take the evidence of two witnesses whose attendance

the next day would be difficult to obtain. Mr. Keeves did not object, and leave was accorded.

Mr. Bertram accordingly called Miss G. E. —, who had not made a declaration, and examined her as to her experience at Mrs. W.'s home. She was cross-examined by Mr. KEEVES, and re-examined by Mr. BERTRAM. No members of the Council desired to ask any questions.

Mr. BERTRAM called Mrs. E. M. C. — as a witness, and examined her as to the truth of her declaration. She was cross-examined by Mr. KEEVES, and re-examined by Mr. BERTRAM. She answered questions put to her by the Legal Assessor and from the Chair.

The Council then adjourned.

(To be concluded next week.)

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

- BAILLIERE, TINDALL AND COX (London).
Diseases of Infants and Children. By Prof. Henry D. Chapin, A.M., M.D., and Godfrey R. Pisek, D.Sc., M.D. Third Revised Edition, with 191 woodcuts and coloured plates. Pp. 596. Price 15s.
- The After-Treatment of Operations: A Manual for Practitioners and House Surgeons. By P. Lockhart Mummery, M.B.Cantab., F.R.C.S. Pp. 285. Illustrated. Fourth Edition. Price 5s.
- Operative Midwifery: A Guide to the Difficulties and Complications of Midwifery Practice. By J. M. Munro Kerr, M.D., C.M. Third Edition, with 303 illustrations. Pp. 790. Price 25s.
- Orthopaedic Surgery. By Edward H. Bradford, M.D., and Robt. W. Lovett, M.D. Fifth Edition, with 369 illustrations. Pp. 426. Price 15s.
- Rhizopod Protozoa, the cause of cancer and other diseases. Being Part IV. of "Protozoa and Disease," by J. Jackson Clarke, M.B.Lond., F.R.C.S. Pp. 202, with sixty-eight illustrations. Price 7s. 6d.
- BURNES AND OATES, LTD. (London).
Who Goes There? By the Author of "Aunt Sarah and the War." Pp. 94. Price 1s.
- CAMBRIDGE UNIVERSITY PRESS.
Cerebro-Spinal Fever. By Michael Foster, M.A., M.D., R.A.M.C., and N. F. Gaskell, M.A., M.D., R.A.M.C. Pp. 222. Price 12s. 6d.
- CHURCHILL, J. AND A. (London).
The Cure of Obesity and Obese Heart. By J. S. Kellett Smith, F.R.C.S. Pp. 93. Price 3s. 6d.
- FANNIN AND CO. (Dublin).
History of the Royal College of Surgeons in Ireland and of the Irish Schools of Medicine, including a Medical Bibliography and a Medical Biography. By Sir Charles A. Cameron, C.B. Second Edition, revised and enlarged. Pp. xv and 882. 1916.
- PROWSE, HENRY, AND HODDER AND STOUGHTON (London).
Nerve Injuries and their Treatment. By Purves Stewart, M.A., M.D.Lond., and Arthur Evans, M.S., M.D.Lond. Pp. 208. Price 8s. 6d.
- HARRISON AND SONS (London).
Links in a Chain of Research on Syphilis (Oxidation and Reduction). Being the Hunterian Lectures delivered before the Royal College of Surgeons, March, 1916. By J. E. R. McDonagh, F.R.C.S. Pp. 206. Price 5s.
- HEFFER AND SONS, W., LTD. (Cambridge).
Tuberculosis and the Working Man: An Appeal to Friendly Societies. By P. C. Carrier-Jones, M.A.Cantab., M.R.C.S., L.R.C.P.Lond., with a Preface by G. Sims Woodhead, M.A., M.D., LL.D. Pp. 47. Price 6d.
- LEWIS, H. K., LTD. (London).
Mentally Deficient Children: Their Treatment and Training. By G. E. Shuttleworth, B.A., M.D., and W.A. Potts, M.A., M.D. Fourth Edition. Pp. 298. Price 7s. 6d.
- Localisation by X-Rays and Stereoscopy. By Sir James Davidson, M.B., C.M.Aberd. Pp. 82. Illustrated. Price 7s. 6d.
- Notes on Galvanism and Faradism. By E. M. Magill, M.B., B.S.Lond. Pp. 236. Price 4s. 6d.
- The Pathology of Tumours. By E. H. Kettle, M.D., B.S. Lond. With 126 illustrations. Pp. 232. Price 10s. 6d.
- LONGMANS, GREEN AND CO. (London).
The Respiratory Exchange of Animals and Man. By August Krogh, Ph.D. Pp. 173. Price 6s.
- METHUEN AND CO. LTD (London).
The Drink Problem of To-day. Edited by T. N. Kelynaek, M.D. Pp. 318. Price 7s. 6d.
- PALMER, CECIL, AND HAYWARD (London).
That Life is the Origin and Purpose of the Universe. By S. G. Palmer Hallett, M.A. Pp. 75. Price 3s. 6d.
- SHAW AND SONS (London).
Clinical Disorders of the Heart-Beat. By Thomas Lewis, M.D., etc., etc. Pp. 116.
- SMITH, ELDER AND CO. (London).
More Minor Horrors. By A. E. Shipley, Sc.D. Pp. 163. Price 1s. 6d.
- WRIGHT, JOHN AND SONS, LTD. (Bristol).
Our Baby. For Mothers and Nurses. By Mrs. J. Langton Hewer. Illustrated. Pp. 208. Price 1s. 6d.

SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Treatment of Tetanus.—Bruce (*R.A.M.C. Jnl.*, November, 1915) gives an analysis of the cases of tetanus that were treated in home military hospitals from August, 1914, to August, 1915. During the period notes were available on the cases of two hundred and thirty-one patients with the disease, and of these one hundred and thirty-three died. In a report that was published in July, 1915, of one hundred and seventy-nine patients treated for tetanus overseas, it is stated that one hundred and forty had died, giving a case mortality of 78.2 per cent. Bruce says that the conclusions to be arrived at by this analysis are as follows:—(1) In the 231 cases of tetanus under review the mortality was 57.7 per cent. (2) Cases with a short incubation period were more fatal than those of longer incubation. (3) Most cases occurred on the tenth day after the wound. (4) There are few allusions to the use of antitetanic serum as a prophylactic. (5) In regard to the therapeutic effect of antitetanic serum, the evidence would go to show that this action was not well marked. (6) If antitetanic serum is used—and in such a fatal disease it would seem wrong not to give the patient the benefit, even if doubtful, of the antitoxin—it ought to be injected in the first place intrathecally, as this method would seem to possess advantages over the intravenous and subcutaneous methods. (7) There is no evidence that any benefit accrued to the patients treated by carbolic acid or magnesium sulphate injections. (8) To sum up, the treatment of a patient with tetanus might be as follows:—(a) Place in a quiet, darkened room, under care of a sympathetic and capable nurse. (b) The best surgical treatment of the wound should be thoroughly carried out to ensure the prompt and complete removal of all septic products. (c) The intrathecal injection of at least 3,000 units of antitetanic serum. At the same time 10,000 to 20,000 units may be injected intravenously and subcutaneously. This procedure to be repeated as frequently as the course of the disease seems to demand. (d) In addition to this the patient should receive sedative drugs, such as chloral or chloretone, in full doses.

K.

Blood Pressure.—Phipps (*Boston Med. and Surg. Jnl.*, September 23, 1915) records the results of a series of observations undertaken with the view of determining the blood pressure in different parts of the body of the same individual. From these investigations he draws the following conclusions:—(1) A difference of 5 or 10 mm. in the blood pressure reading may be observed, dependent on whether the pressure be determined by palpation or auscultation, but neither method can be said to be the more accurate. (2) The blood pressure reading may vary in the same individual between the right and the left arms, thighs, or calves, or between arm, thigh, and calf; this variation is in no way uniform. (3) The variations are apparently as great in young individuals as in old, and in patients showing healthy arterial walls, as where there is arterio-sclerosis. (4) The location of the artery, especially in its relation to other structures, such as bone and muscle, probably is of much greater importance in determining the blood-pressure reading than is the thickness of the overlying tissues. (5) Difference between the right and left brachial pressures is by no means diagnostic of aortic aneurysm. (6) The presence of a higher pressure in the leg than in the arm is not diagnostic of aortic insufficiency, although this has been stated by previous observers. (7) Blood pressure in the vessels of the leg and the arm is not "practically the same."

K.

Migraine.—Saint Remy (*New York Med. Jnl.*, March 25, 1916), as the result of personal experience, and observation on others, attributes the phenomena pre-

sented by this condition to intermittent nasal obstruction. He says:—"Pressure upon the sphenopalatine ganglion, caused by swelling of the middle turbinate impinging against a relatively high deviation of the nasal septum, by disturbance of the local circulation, ends in a reflex spasm of the cerebral vessels, which accounts for all the remote symptoms, to wit, the vertigo, nausea, vomiting dullness, oppression, etc., which appear in turn. Once this ætiology is grasped it becomes clear why the disease comes on about the age of puberty, for it is then the nasal septum begins to bend from pressure upon it by the faulty development of the facial bones. The disproportionate growth of the frontal and maxillary causes the vomer to yield. Thus also is made clear the reason for the spontaneous cessation of the disease late in life, when the nasal mucosa is no longer erectile."

K.

Radical Operation for Carcinoma Uteri.—Taylor (*Surg., Gyn., and Obs.*, xxii., 4) says of the two routes, abdominal and vaginal, that the former is the first choice, but if there is a combination of a thick abdominal wall with a roomy vagina, and some prolapse of the uterus, the vaginal route will be the better. The difference between simple and radical hysterectomies is the amount of pelvic connective tissue removed with the uterus. The extent of the operation performed for the removal of any malignant growth is limited by the risk to the life and the amount of mutilation of the patient. The mutilation can be ignored, except that the greater the amount of tissue removed the greater the risk. For growths of the same extent in patients the primary mortality is only moderately greater in the radical operation, and the advantages outweigh this. Injuries to the bladder are considered the result of the disease rather than of the difficulties of the operation. The extensive separation of the bladder is probably the cause of the frequent cystitis afterwards. Hæmorrhage is a serious difficulty, and is responsible for a number of deaths; ligation of the anterior branch of the internal iliac will help to control this. The risk of infection is probably no greater than in the simple hysterectomy. For the favourable case, in good condition, and moderate abdominal wall, and no associated pelvic lesion, the radical operation is advised; for a limited growth in a poor subject a simple abdominal hysterectomy, or occasionally a vaginal one. For inoperable cases radium, the X-ray, or cautery treatment is recommended.

F.

Roentgen Treatment of Uterine Carcinoma.—Case (*Surg. Gyn., and Obs.*, xxii., 4) says that, considering the great number of cases which have undergone Roentgen treatment, the percentage of clinical cures is very small. Anatomical examination has shown the possibility of complete removal of operable and inoperable uterine cancer, but what percentage of permanent cures cannot as yet be stated. The condition of the cases is greatly improved in general health by relief of pain and discharge, and the fatal results are postponed and mitigated. The advantage of cautery treatment in combination is considered unquestioned in inoperable cases, but in operable cases the alternative of Roentgen therapy should never be offered, and all cases after operation should be treated by the rays.

F.

Radium in Carcinoma of the Cervix Uteri.—Miller (*Surg. Gyn., and Obs.*, xxii., 4) says that surgery is the only treatment so far known that offers a permanent cure for cancer in the early stages of the disease. If the percentage of ultimate cures is increased it will be by continuing earlier operation with other therapeutic agents, the most promising being X-rays or radium. Border-line cases are not advised for the

radical operation, as the risks are not justified by the results, and radium or X-rays gave as great or greater amelioration of symptoms. No proof of increase in operability by preliminary radium treatment is available, but improvement appears to have occurred, and to justify the hope that operation would be successful. The consequent increase in connective tissue would probably increase the difficulties of operation. It is thought that cauterisation prior to radium treatment is not the best procedure, as it requires longer to check the local symptoms and the subsequent histories do not show that the cases remained well any longer. The effect of radium can only be proved by the length of time after treatment, and that has not yet been obtained. It eradicates the surface disease, but that it is capable of reaching the outlying areas is not established. Radium has no field absolutely to itself, but should be used in common with other methods.

F.

Metastatic Carcinoma of the Ovaries.—Stone (*Surg., Gyn., and Obs.*, xxii., 4) says that malignant tumours of the ovaries, even when of such size as to control the clinical course of the disease, are frequently secondary growths, especially from the stomach and the breast, and this should always be recognised in the treatment and prognosis. The route of metastasis is rarely a chance distribution of emboli, but occurs by direct extension through the retro-peritoneal lymph-nodes or peritoneal implantation, this latter being especially liable to occur during the period of the ovarian functional activity. The histology of ovarian tumours varies with the nature and location of the primary growths; the adenocarcinomatous type appears to be frequent, but a larger number are of the diffuse infiltrating type, in which the glandular structure is lost, but a fibro-carcinomatous structure is seen.

F.

Mercury in the Treatment of Pyorrhœa.—Barton L. Wright (*Medical Record*, May 6th, 1916) regards pyorrhœa alveolaris as one of the most frequent and widespread of infections, and one of the most dangerous to the infected. He places much stress on efficient local treatment. He administers a deep muscular injection of one grain of mercuric succinimide every seventh day until the discharge of pus has disappeared and the gums have regained their normal condition. In female patients the dose should be one-fifth to two-fifths of a grain less than in males. The drug was dissolved in hot sterile water. The longest period required to effect a cure was forty-one days, the shortest four days; the average was seventeen days. The treatment was given in seventy-five cases, in forty-one of which there were signs of systemic infection. In every case the systemic as well as the local evidences of the disease disappeared.

OBITUARY.

DR. JAMES THORNTON MACPHERSON,
CHORLTON-ON-MEDLOCK, MANCHESTER.

THE death is announced of Dr. James T. Macpherson, of Manchester. He graduated M.B.C.M. at the University of Aberdeen in 1887 and M.D. in 1905, and for the last 25 years practised in Manchester, where he was highly esteemed.

DR. J. E. S. PASSMORE, M.R.C.S., L.R.C.P.,
GAINSBOROUGH.

THE death took place at Gainsborough, of Dr. John Edmund Sandars Passmore, one of the best-known public men in the county of Nottingham. Dr. Passmore, who was a native of North Molton, North Devon, had been resident in Gainsborough 24 years, and was 57 years of age. He was educated privately and at the London Hospital, and became M.R.C.S., L.R.C.P.Lond., in 1892. He was created justice of the peace for the Parts of Lindsey in 1907, and for a number of years he represented the North Ward of Gainsborough on the County Council. He was one of the most active members of the Lincolnshire

Nursing Association, and was one of the original members of the Gainsborough Urban Council. During the absence of his partner, Dr. Smith, on military service, he had acted as deputy medical officer of health for the Gainsborough rural district. Dr. Passmore leaves a widow and one son.

DR. S. CATHCART, M.R.C.P., L.R.C.S.,
HIGHGATE.

WE regret to record the death of Dr. Samuel Cathcart, a well-known medical practitioner in Highgate, who passed away on May 14th at the age of 64. About three months ago the deceased contracted influenza while visiting a patient late at night, and pneumonia supervened. He was educated at Edinburgh University, and qualified L.R.C.P. and S. in 1876. He came to London soon afterwards, and until 1897 practised in Tottenham, whence he removed to Highgate. Dr. Cathcart was keenly interested in cycling and motoring, and journeyed from London to Northumberland, his birthplace, on one of the first machines to be fitted with pneumatic tyres. It is believed that he was the second doctor in Highgate to use a motor car in his practice. He leaves a widow, three sons, and two daughters.

DR. ALFRED GRACE, M.R.C.S., L.S.A.,
CHIPPING SODBURY.

THE death is announced of Dr. Alfred Grace, the last survivor of the five brothers, of whom Dr. W. G., Dr. E. M., and Fred attained such exceptional distinction in the cricket field. Alfred was born at Downend, near Bristol, in 1840. Educated at Bristol, he qualified M.R.C.S. in 1863 and L.S.A. in 1864. For many years practised at Chipping Sodbury, Gloucestershire. Like his more famous brothers, Dr. Alfred Grace was well known as a cricketer, but at no time did he rank with his brothers. In local cricket he scored several innings of over a hundred, and when only 15 years old he formed one of 22 of West Gloucestershire who met the All England Eleven at Bristol. He was recognised as one of the finest horsemen in England, and for many years followed the Duke of Beaufort's hounds three or four days a week. He was formerly Surgeon Lieutenant-Colonel of the Royal Gloucester Hussars Yeomanry Cavalry.

MEDICAL NEWS IN BRIEF.

Seats in Lifts.

THE Home Secretary calls the attention of occupiers and managers of business premises who have taken on or may be taking on women and girls to act as lift attendants to the need which exists in certain circumstances for allowing the attendants facilities for resting in the intervals of work.

There is a growing tendency, with a view to increasing the passenger accommodation, to make lifts without seats. He urges the provision of an attendant's seat when other sitting accommodation is not available, and in specially heavy cases, where work is practically continuous, recommends that one or two short intervals should be allowed for purposes of rest. A convenient form of seat, which is now being provided in some new lifts, consists of a wooden flap which closes flat against the side of the lift when not in use.

Devon and Cornwall Sanatorium.

THE thirteenth annual meeting of the Devon and Cornwall Sanatorium for Consumptives at Didworthy and King Edward VII. Memorial Dispensary for Tuberculosis, Plymouth, was held at Plymouth.

The annual report stated that there were 70 beds at the Sanatorium, 40 for men and 30 for women. The daily average of patients was 60. The accommodation was therefore sufficient to meet normal demands for admission. During the year 272 patients (20 more than the previous year) had been under treatment. The average period of treatment for each patient was 103

days. Of cases admitted, 114 were in the first, 123 in the second, and 35 in the third stages of the disease. The increase in the cases admitted in the first and second stages of the disease was a very encouraging sign. Treatment at the earliest possible moment could not be too strongly insisted upon. The committee had given the first call on beds to tubercular soldiers and sailors. In spite of war prices, the average total cost per in-patient had only increased 1s. 8d. per week. The balance-sheet showed the total income £5,011, and a debit of £41 7s. 1d.

Women and Medicine at Cambridge.

At a Congregation of the University of Cambridge on June 2nd, a Grace will be offered to the Senate throwing open the first and second M.B. examinations and the examination in architectural studies to women. The usual procedure of publishing a report and recommendations and discussing them before taking a vote has not been followed, and a vigorous protest was issued on May 27th in a fly-sheet signed by the Master of Jesus, the Master of Pembroke, and ten others, who announce their intention to vote *non-placet* to the Grace for the following reasons:—

No report has been presented by either Board: there has been no discussion of the recommendations. The Senate is asked to vote without information and without debate. The question whether women should be admitted to the medical examinations of the University raises difficult and complex problems which require careful consideration. Further, it involves serious issues of a controversial nature. We feel strongly that it is undesirable that such proposals should be brought forward at the present time, when so many members of the Senate are away from Cambridge on national service. We object still more strongly to the procedure adopted. Recommendations are presented without reports justifying them. They are not submitted to discussion, but we are told that they have received the approval of the General Board of Studies and of the Local Examinations and Lectures Syndicate. We do not think that the Senate ought to be asked merely to register the proposals of Special Boards brought forward without explanation. We fail to understand why the General Board and the Local Examinations and Lectures Syndicate should be consulted when the Senate is not consulted. We do not think that the powers of the Senate to approve should be delegated to these bodies. We suggest that the ordinary procedure should be adopted: that the Special Board for Medicine and the Board of Architectural Studies should be asked to present reports, that in due course these reports should be discussed in the Senate, and that the Council should consider any proposals or amendments pertinent to the subject. If, after discussion, it is decided to proceed further, we suggest that proper time for consideration should be allowed before the Graces are offered.

Metropolitan Asylums Board.

At a meeting of the Metropolitan Asylums Board on May 27th, it was reported that the Ministry of Munitions had given instructions for the discontinuance of building work at Tooting Bec Asylum on grounds of urgent national importance. Mr. W. H. Ecroyd said that it was a question whether national importance would not be better served by keeping such buildings going on. Hardly a man who was stopped at the County Hall was given work by the Government. The Clerk explained that the men were required for building munition factories, and the matter was referred to the Works Committee.

Work for the Ambulance.

At the request of the Liverpool school-children, the Lord Mayor on May 24th handed over to the Countess of Derby (representing the Liverpool branch of the Red Cross Society) a motor-ambulance, for which the money was raised by the children collecting and selling medicine bottles. A big crowd of people witnessed the ceremony, which took place on St. George's Plateaux. At the conclusion an ambulance ran into the crowd and four persons were injured.

Swiss Doctors to Examine German Prisoners.

REUTER'S Agency learns that the Commission of Swiss doctors, under the charge of Lieut.-Colonel Sturzenegger, of the Swiss Army Medical Service, has arrived in London. The Commission is charged to examine German prisoners of war in this country who are to be sent to Switzerland for special hospital treatment. The Commission will visit all prisoners' camps, both in Germany in the case of English prisoners, and in England in the case of German prisoners, and every prisoner will have the right to present himself for examination.

Devonport Royal Albert Hospital.

By means of a house-to-house collection £820 has been collected in aid of this institution. Promises of weekly, monthly, and yearly subscriptions have also been received.

Small-pox and Soldiers.

AN Army Order states that owing to the occurrence of small-pox in various parts of England and Wales soldiers' leave will be curtailed.

Soldiers will not be allowed to proceed on leave to their homes in parts of the counties of Lancashire, Northumberland, Durham, Glamorganshire, and Monmouthshire.

Incidence of Infectious Diseases.

THE Local Government Board has recently issued a report on the Statistics of the Incidence of Notifiable Infectious Diseases in each sanitary district of England and Wales in 1915 (New Series, No. 109. 1916. Price 6d.). The following are the total numbers of the chief notifiable diseases notified, excluding cases among sailors and soldiers:—Pulmonary tuberculosis 73,358 other forms of tuberculosis 22,864, small-pox 90, typhus 45, scarlet fever 127,086, diphtheria 53,597, enteric fever 6,364, continued fever 63, puerperal fever 2,057, erysipelas 23,382, cerebro-spinal fever 2,566, poliomyelitis 517, ophthalmia neonatorum 6,806.

THE death is announced of Mr. Basil A. Dyer, Coroner of Bath for the past 26 years.

THE death occurred last Saturday of Dr. Charles E. Fitzgerald, Honorary Surgeon Dentist to the King in Ireland, and ex-President of the Royal College of Physicians of Ireland.

A GLASGOW citizen who desires to remain anonymous has acquired Erskine House and 350 acres of ground and presented them to the Princess Louise Hospital for Scottish limbless sailors and soldiers.

MR. WILLIAM PHILIP, of Boynds Keith Hall, Aberdeen, left £1,000 to the Inverurie Town Council, the income to be applied for the maintenance of a qualified nurse for the Burgh and neighbourhood.

CAPT. FREDERIC GEO. ALLEYNE ARKWRIGHT, who was killed in an aeroplane accident on October 14th last, and a descendant of the inventor of the spinning jenny, left £50 to Miss Morgan, nurse at the Cottage Hospital, Ashbourne, "when I was ill there in 1912."

MISS CHARLOTTE EMILY BECKWITH, of Southport, bequeathed one-half of the residue of her estate, which amounts to about £8,000, to the Victoria University of Manchester in aid of the "John Henry Beckwith Scholarship" founded by her mother, and one-fourth each to the Manchester Infirmary and the Southport Infirmary.

DR. THOMAS BURNIE, L.R.C.P., L.R.C.S., of 389 Mansfield Road, Nottingham, first President of the Nottingham Medico-Chirurgical Society, for many years Chairman of the Nottingham House and Land Company, and who died on September 23rd last, aged 77 years, left estate of the gross value of £24,011 5s. 4d., of which £4,032 18s. is net personality.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

LETTERS TO THE EDITOR and Original Papers intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of *bona fides*. These should be addressed to the Editor at the Offices of this Journal; if in Ireland, to the Dublin Office, 29 Nassau Street; from all other parts of the United Kingdom these should be addressed to the London Office, 8 Henrietta Street, Strand.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 2ls., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

FLIES AND DISEASE.

WARNINGS about the danger of flies as carriers of disease germs are being issued by the Lambeth Borough Council.

VALUABLE MEDICINE BOTTLES.

MEDICINE BOTTLES gathered in a house-to-house collection in Islington have been sold for about £300. The money is being devoted towards the purchase of a motor ambulance for the front.

A DIAGNOSIS.

WHEN a doctor is irritable, it may be because he is out of patients.—*Pall Mall Gazette*.

DR. JOHN KNOTT.—Owing to pressure on our space your communication is unavoidably held over till our next.

MEDICAL APPEAL TRIBUNAL.

MR. PHILIP SNOWDEN is to ask Mr. Tennant if he will create an Appeal Medical Board, containing some civilian doctors, to whom recruits may appeal if they are not satisfied with the decision in the first medical examination.

THE KNOCK OUT!

JIMMY WILDE, the British fly-weight boxing champion, has for the second time been rejected for Army service by the Medical Board, this time on account of deficiency in weight.

DOCK RATS.

DR. WILLOUGHBY, Medical Officer of Health for the Port of London, reports that during last year 42,491 rats were caught and destroyed in dock warehouses and vessels in the docks and rivers.

Meetings of the Societies, Lectures, &c.

THURSDAY, 1ST JUNE.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1, Wimpole Street, W.),—5 p.m.: Adjourned Discussion; On Mr. J. E. R. McDonagh's paper on "The Rationake and Practice of Chemotherapy."

FRIDAY, 2ND JUNE.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.),—8.30 p.m.: Paper; Dr. J. Dundas Grant, "Some Points of Practical Interest in the Diagnosis and Treatment of Diseases of the Throat, Nose and Ear."

Vacancies.

County Asylum, Whittingham, Preston, Lancs.—Assistant Medical Officer. Salary £250 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with board, rooms, attendance and washing. Applications to the Secretary.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Lady House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38, Barton Arcade, Manchester.

Bury Infirmary.—Lady Junior House Surgeon. Salary £150 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.

London Temperance Hospital, Hampstead Road, N.W.—Assistant Resident Medical Officer. Salary £120 a year, with residence, board, and laundry. Applications to the Secretary.

The Royal Infirmary, Sheffield.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

Royal Devon and Exeter Hospital, Exeter.—House Physician. Salary £150 per annum, with board, apartments, and washing. Applications to Samuel S. Cole, Secretary.

Appointments.

CARRUTHERS, N. S., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for the Acle District of the county of Norfolk.

GLOVER, V. J., M.D.Liv., Ch.B.Vict., Medical Officer of Health for the Waterloo and Seaforth U.D.C., and Schools Medical Officer.

HILLIER, W. H., M.D.Dur., Certifying Surgeon under the Factory and Workshop Acts for the East Grinstead District of the county of Sussex.

Births.

BRIDE.—On May 23rd, at Beechwood, Eccles, the wife of T. Milnes Bride, Lieut., R.A.M.C., of a daughter.

GARDEN.—On May 21st, at 202, Bedford Hill, S.W., the wife of Temp.-Captain A. S. Garden, R.A.M.C. (of Colombo), of a son.

GOOD.—On May 23rd, at Dobbs, High Bickington, N. Devon, the wife of Arnold S. Good, M.R.C.S., L.R.C.P., of a son.

HAYDEN.—On May 25th, at 192, Wymering Mansions, W., the wife of Captain A. F. Hayden, M.B., F.R.C.S., I.M.S. (ret.), of a son.

HIGGS.—On May 21st, at "Dunedin," Egmont Road, Sutton, Surrey, the wife of Major F. W. Higgs, M.D., R.A.M.C. (T.F.), of a daughter.

HODDER.—On May 26th, at 160, Sandon Road, Stafford, the wife of Lieut.-Colonel A. E. Hodder, R.A.M.C. (T.), of a daughter.

KINLOCH.—On May 26th, at The White House, St. Albans, the wife of R. Blair Kinloch, M.B., M.R.C.S., of a son.

ORCHARD.—On May 25th, at Crewkerne, Somerset, to Eleanor H. (née Phillimore), the wife of Lieut. J. Russell Orchard, R.A.M.C., a son.

Marriages.

BOLT—RINGLAND.—On May 23, at St. Anne's Church, Lewes, Capt. Richard Frank Bolt, R.A.M.C. (T.C.), third son of J. F. Bolt, Esq., of Westbury-on-Trym, Bristol, to Effie Lyndall, younger daughter of the late W. R. Ringland, of Belfast, and Mrs. Ringland, of Lewes, Sussex.

DRYDEN—GIDLEY.—On May 22nd, at St. Mary's, Christchurch, New Zealand, Douglas Dixon Dryden, Capt. New Zealand Medical Corps, of Barnard Street, Timaru, Canterbury, New Zealand, to Mary Northleigh, daughter of the late Gustavus Gidley, Esq., of Plymouth, S. Devon.

HEY—BROWN.—On May 23rd, at the Wesleyan Chapel, Darcy Lever, Bolton, Wilson H. Hey, F.R.C.S. (England), Captain, R.A.M.C., of Manchester, to Elsie Brown, M.B., Ch.B., eldest daughter of Mr. and Mrs. T. H. Brown, of Ashbourne, Bolton.

HILL—LANGRIDGE.—On May 23rd, at Newmarket, Rowland Hill, M.D., M.R.C.P.Lond., Temp. Surg., R.N., son of the late Squire Hill, J.P., Ballyclare, Co. Antrim, to Gertrude, daughter of the late Arthur Langridge, Leytonstone.

RYLAND—MOORE.—On May 17th, at The Hirsell Private Chapel, Coldstream, N.B., Capt. Archer Ryland, F.R.C.S. (Edin.), and R.A.M.C., son of Mr. and Mrs. Henry Woodcock Ryland, of 43, Holland Park, London, W., to Gladys Mary, daughter of the Rev. C. A. Moore, Domestic Chaplain to the Rt. Hon. the Earl of Home, K.T. and Mrs. C. A. Moore, of The Hirsell, Coldstream, N.B.

Deaths.

ALEXANDER.—On May 26th, at Ashwick, Poole Road, Bournemouth West, suddenly from angina pectoris, William Alexander, M.D., in his 54th year.

GOODHART.—On May 28th, at 25, Portland Place, W., Sir James Frederic Goodhart, Bt., M.D., F.R.C.P., aged 70.

HAROLD.—On May 27th, at 65, Harley Street, after a long and painful illness patiently borne, Dr. John Harold.

KIMBELL.—On May 28th, at a nursing home in London, Lieut. Harry John Sullings Kimbell, R.A.M.C., of Richmond Road, Hackney, until recently in charge of Preston Hall Hospital, Maidstone.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, JUNE 7, 1916.

No. 23.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Circular W. 41.

THE Central Medical War Committee, under date May 27th, issued a circular explaining the position of medical men under the Military Service Acts, which is worthy of careful attention. Having regard to the fact that the signatories are still Dr. Alfred Cox and Mr. Bishop Harman, writing from 429, Strand, it is a pleasant surprise to find that the tone of the circular is free from the blemishes which have characterised some of its predecessors. It may safely be read without a previous dose of bromide. The circular sets forth that enrolment with the Central Medical War Committee enables a medical man who is of military age (*i.e.* under 41) to escape the attentions of an ordinary Recruiting Officer, an official who might otherwise place a doctor in the ranks where his special knowledge would be useless. In these days, when all and sundry are being turned into soldiers, it is an advantage to be an officer, and this privilege is secured to anyone who enrolls with the Committee.

The New Style.

THE circular also points out that the Central Medical War Committee will almost certainly be recognised as the Tribunal in matters medical, and that consequently a great deal of time and trouble will be saved if medical men of military age will enrol at once, whether or not they intend to claim exemption. This is quite reasonable, and is quite tactfully stated. On the question of the age limit for medical men, announced as 45 years, the language of gentle persuasion in the present circular is strikingly different from the bullying note which was so conspicuous in some of the earlier ones. This age limit was, of course, invented by the Committee, and has no legal support of any kind. The invention was not in itself unreasonable or objectionable, and when presented in its newer form it may well appeal to many who were disgusted and repelled by its former verbal garments. The literary manners of Dr. Alfred Cox and Mr. Bishop Harman show considerable improvement. Their literary style, however, does not. The fourth paragraph of the circular begins with the inexcusably illiterate "Firstly." But that is a small matter.

The Gist.

THE gist of the Circular may be said to be contained in the following paragraphs, which I cordially commend to the consideration of all concerned.

"Every unenrolled medical man of military age who is not a conscientious objector is urged to enrol without delay in order to save both himself and the local Tribunals the trouble of dealing with an appeal which, in the circumstances explained above, will in any event be referred to the Central Medical War Committee. As you are already aware, enrolment involves an obligation to take a Commission in the R.A.M.C. as and when required by the Central Medical War Committee after consideration of all the relevant circumstances."

"If you are over 41 but have not yet reached your 45th birthday you are still eligible for general military service in a medical capacity. All the medical officers needed by the Army cannot be supplied from the men under 41 without great inconvenience and indeed hardship to some of these men and to some areas of the country. We suggest to you that a sense of professional duty and a spirit of fairness will lead you to enrol, so that the necessary selection may be made from as wide a field as possible."

With the concluding sentence I am very pleased to find that I am in entire accord.

An Appeal Board.

THE Central Medical War Committee, or the Advisory Committee of the Royal Colleges, or both, would do well if, before it is too late, they made representations in the proper quarter to secure the recognition of a board of appeal from the decisions of those who are engaged in the medical examination of recruits. As matters stand at present there is no appeal of any kind, with the natural result that men who are physically quite unfit are being kept in idleness at the expense of the state. The medical examination of recruits is necessarily a somewhat perfunctory performance. It would be impossible to examine every man with the same care that would be bestowed upon him were he a candidate for life insurance, and many are consequently accepted, or rather conscripted, who ought not to be. A fair proportion of these know themselves to be unfit

and produce medical certificates to that effect; they are nevertheless made to "fall in." I do not wish to minimise the difficulties of the situation, but a good many of them, and several very real grievances, would disappear with the constitution of a really competent Board of Appeal.

Its Necessity. THE necessity for some appeal from the verdict of the recruiting medical officer has been apparent to the observant for several months past, but the advent of compulsion invests the matter with urgency. The examiner cannot be expected in every case to go into such minutiae as the presence or absence of albuminuria or glycosuria, the estimation of blood pressure, or the state of the fundus oculi, and yet facts might easily emerge from such investigations which would put a totally different complexion upon the acceptability of a candidate who, to cursory examination, appeared to be highly suitable. At one time some medical examiners would not even look at a certificate brought by a candidate. I do not know whether this has now been altered, but it is obvious that the sole responsibility should not rest upon one man. There should be a board to which the examiner could refer doubtful cases and to which dissatisfied recruits could have reasonably easy access.

Medical Law Reform. THE letter which appears in this issue from the facile pen of Mr. Henry Sewill is, in a sense, a continuation of the one which we published last week. They reopen a question upon which, as he properly says, the general practitioner is very partially informed, and he rightly insists that this ignorance is due in very large measure to the British Medical Association. It is not so very long ago—in the days before the Insurance Bill—since the Association really represented the profession. Doctors were told that it existed to further and defend their interests, and apparently believed that somehow or other it did so. Then came the Insurance Bill and the great awakening. During the period of its power and authority the Association, through its *Journal*, had a magnificent opportunity to educate not only professional, but also public opinion in matters which a little foresight would have told it would some day become vital to our independence. It did nothing; with the result that we now have to face a gathering storm unrepresented, unorganised and unprepared. I hope Mr. Sewill will continue to address us, not on the subject of the B.M.A., but on the questions of medical law reform upon which he is so high an authority.

The Moment. It is certain that with the war and its aftermath really at an end, men's mental attitude towards many things will be found to have undergone a very profound change. The efficiency and self-sacrifice of the medical contribution to the colossal struggle is on everyone's lips, and the public is consequently as well disposed towards us as it is ever likely to be. If ever there was a time at which we could press for medical law

reform with some prospect of success, that time will be in the immediate future. If Mr. Sewill will continue his instructive letters he will do much to educate professional opinion upon these important matters. And professional opinion is badly in need of education. We are hopelessly blind to our interests and inconceivably tolerant of encroachments.

A Letter from Mr. Miles. THE letter from Mr. Eustace Miles, for my acknowledgment of which the printer found such an original place in last week's issue, is dated May 22nd. It is in further reference to the following words which appeared in the "Periphery" on April 26th: "We can look with indulgence upon the degenerates who listen with trituristic fervour to Mr. Eustace Miles' pseudo-scientific siftings from the scullery." In connection with this passage I received a long letter (it filled six pages of typewritten MS.), to which I briefly referred in our issue of May 17th. Mr. Miles' present letter begins as follows: "Your note with regard to my letter in reply to the words used about me in your previous letter (he means article) will not do at all." This was startling, and I read on in some trepidation. My nervousness was soon justified by the following truly alarming passage: "I am afraid, if you are going to pass the matter off so lightly, I shall have no alternative but to urge some hundreds of those who have consulted me, to sue you for libel, on the strength of your having called them 'degenerates.'" I invite Mr. Eustace Miles at once to set about his canvass for candidates to sue me; I shall be much interested to know how it progresses.

Three Propositions. MR. MILES concludes his letter with three propositions categorically stated. "First, that I am doing work which doctors do not do." I am not concerned to deny this; neither am I prepared to assert that it is discreditable to doctors that they should decline to place themselves in competition with Mr. Eustace Miles. "Secondly, that I have succeeded in helping thousands of people, where doctors have failed." This is indeed a grandiose claim: but Mr. Miles has no monopoly in it. All unqualified practitioners, from Sequah to Mrs. Eddy, have said much the same thing in much the same terms. "Thirdly, that qualified medical men have put themselves in my hands for dieting." To which, I again reply that I find no difficulty whatever in believing it. The circle of professional orthodoxy is wide enough to include not only all sorts of cranks and faddists, but also earnest seekers after physiological salvation who are prepared to give a trial to anything, however commercial and uninviting. It does not therefore surprise me to know that some of these have been tempted to sample the delights which I am assured await them at Mr. Eustace Miles' Restaurant. But I am in a state of nervous prostration about that libel action.

SINAPIS.

THE TREATMENT OF WAR PSYCHOSES.

THERE are frequently accounts in the public press of the cure of the various psychoses produced by the war and its effects, either by accident, as in the torpedoing of the *Lusitania*, or by design, as in suggestion.

Now, it is known that large numbers of men are being returned useless from the front every week suffering from what is collectively termed "shell-shock," and the question naturally arises as to what system of treatment is being adopted, and how far it conforms to the necessity of the case. As far as we can ascertain, there are two methods being used. One is the provision of a wholly inadequate number of hospitals, where all cases are collected together without any attempt at classification. The patients seem to be in charge of a number of doctors whose qualifications for dealing with this class of injury seem to be as miscellaneous as the various types of cases. In fact, as can be gathered from the papers on these conditions which are so frequently communicated to the medical press, the doctors in charge seem to be much more concerned in describing the conditions than in curing them. In January last, a discussion lasting for two evenings took place on "Shell Shock" at the Royal Society of Medicine, at combined meetings of the Sections of Neurology and Psychiatry. The last speaker on the second evening, Dr. Leonard Guthrie, drew attention to the fact that practically nothing had so far been said about treatment. The general trend of such treatment as was mentioned seemed to be to leave the patients alone and hope for their recovery, for this did fairly often take place.

The other method now employed is the same in principle, but the patients are boarded out for rest cures (?) in cottages in the country instead of being collected into hospitals.

Now, compared with this, the system adopted by other combatant nations is far more thorough and efficient. Each nation has a number of suggestion hospitals, where cases are sent as soon as possible, and where they receive treatment by suggestion from the earliest possible moment. Perhaps this is one of the reasons why the Germans boast of returning so much larger a number of the injured to the ranks compared with ourselves. In fact, the proper treatment of these cases is by suggestion, but by suggestion given properly and thoroughly by those who know how to do it.

Here, then, we come to the crux of the whole matter. In all foreign countries, treatment by suggestion was a common practice before the war, and the public were conversant with it, a large number of doctors practised it, and all doctors understood what could be accomplished by it. In this country, on the other hand, few practised it, fewer still of these knew much beyond the theory, and the general medical public was, and still is, as ignorant of its principles and practice as the general mass of the population.

Owing to these facts, it is no exaggeration to say that many thousands of men are suffering

indefinitely, possibly for the rest of their lives, from the various forms of traumatic psychoses, who could be very rapidly cured and rendered efficient soldiers if only the right treatment were adopted. One cannot help noting in the published articles that towards the end the writer nearly always gives his opinion that these cases are not suitable for suggestion treatment. Why they are not suitable, does not appear. The inference is irresistible that the writer is totally unacquainted with the method. One is reminded in this connection of the time when Lister was demonstrating at King's College Hospital his antiseptic treatment. It was then the vogue for surgeons, brought up in the old school and too hide-bound to learn or even grasp the new surgery, to protest *urbi et orbi* their disbelief in Lister's teaching. It is the natural defence of the old order against the new. But this is no time for allowing soldiers to remain sick and a great expense to the country, when they are wanted in the active army.

It may be argued that there are very few doctors who understand suggestion, and that there are thousands of patients constantly arriving home who require this treatment; how, then, is it possible to supply the want?

The answer would be, first to point out what is being done in other matters medical, where, as in surgical cases, there are not enough doctors to do all the dressings; these are deputed largely to unqualified persons, such as nurses, probationers, and V.A.D. nurses acting under more or less surgical supervision. Just as the efficiency of the V.A.D. hospitals depends entirely on the efficiency of the commandants, so would the efficiency of the suggestion hospitals depend upon the head control. We should propose, first, a model hospital as an example, and when that had proved a success, it could be copied with ease as many times as was required. As a fact, owing to the neglect of suggestion treatment by the profession at large, there are a number of persons practising suggestion who are not qualified doctors, and these are members of both sexes. Some of these suggestionists are endowed with great powers, and frequently effect cures on cases which have been pronounced incurable by practising physicians. And this not indeed in opposition to the physicians, but simply from inability to procure any direction or supervision from them, which we know many of these suggestionists would welcome. There can be no more rational objection to employing these people under medical control than there can be to employing masseurs, electricians, medical gymnasts, X-ray operators, and so on, where, for various reasons, such as, for instance, expense, medical men are not available or the medical man in charge is not sufficiently versed in the practical details. The particular scheme we most favour is that of teaching nurses, and others who have been already associated with medical work. Thus they would fit easily into their places in a suggestion hospital, for given certain essentials of personality, an ordinarily intelligent person can be taught enough in a few days for the purpose of carrying out suggestions as prescribed.

We use the term suggestion hospital in preference

to that of hypnotism hospital, for the reason that patients can be very energetically "suggestionised" without being hypnotised. There are, indeed, three forms in which suggestions may be given—viz., waking suggestion, sleepy or hypnoidal suggestion, and sleeping or hypnotic suggestion. All three are easily covered by the term suggestion. There is another point we would emphasise about this mode of treatment—viz., that to be effective it must be given in sufficient doses, and repeated often enough, and no antidotes in the way of contra-suggestions must be allowed. For this purpose there must only be one doctor in supreme control for each hospital, and all the nurses and attendants must be acting in concert with him. By this means only can an atmosphere of continuous suggestion be kept up and rapid progress made.

Our scheme, then, for a model suggestion hospital would consist of a unit of 100 cases entirely under the control of one medical man who was known to be an efficient psychotherapist. He would be responsible for all treatment, and with powers to call in, as occasion arose, specialists for the diagnosis of exceptional cases. Acting under him would be a certain number of persons well trained in suggestion treatment who might, or might not, be trained nurses as well. The duties of these would be to carry out daily the suggestions prescribed for each case by the doctor, and to train others in this method of treatment. Very soon a number of these could be spared to be grafted on to another model hospital as formed, and so on. These, with matron, housekeeper, nurses, servants, etc., as in ordinary hospitals, would be all that would be required.

By adopting these principles a standing need would be met, and the reproach of our present neglect would be removed.

As regards cost, whatever the expense of providing and financing these hospitals might be, it would be a mere drop in the ocean compared with what the country now has to pay in keeping and pensioning the thousands of soldiers who might by these means be restored to health and usefulness.

CURRENT TOPICS.

Chadwick Lectures on Measles.

DR. CATES, Medical Officer of Health, St. Helens, delivered, on May 25th, at the rooms of the Royal Society of Medicine, the first of two lectures on Measles, under the auspices of the Chadwick Trust. He summarised the history of the disease and showed how in the past measles epidemics had destroyed practically one quarter of the population of a district. He pointed out that in England and Wales 10,000 children died from the disease every year and at least an equal number were left permanently disabled. Since the commencement of the war there had been serious outbreaks of measles amongst the troops in several areas.

Dr. Cates stated that the occurrence of an epidemic could be foretold with almost mathematical certainty, and there was therefore little excuse for those sanitary authorities to allow an outbreak to find them unprepared.

The lecturer said that in clean homes and in

good surroundings healthy children rarely failed to make a good recovery. On the other hand, the death rate from measles among infants of unskilled labourers was nearly four times as great as that of children of the upper and middle classes.

As the main cause of death in measles was infection set up by an unhealthy condition of the mouth, nose and throat, it was hardly a matter for surprise that a heavy toll was exacted from among families living in insanitary surroundings. A child whose playground was the unswept street, whose idea of hide and seek was confined to a romp in an alley in which filth and garbage were lying, whose voyage of discovery was limited to a search for cigarette cards among the contents of ashpits, was unlikely to possess a healthy nose and throat. Dr. Cates appealed for the general extension of treatment to children under school age, and urged that the plea of economy should not be allowed to jeopardise the health of the nation. It was essential even at the present time that insanitary property should be dealt with, that regular and frequent removal of house refuse should be carried out, and that the streets and passages should be kept in a clean and wholesome condition.

In the second lecture, delivered on June 1st, Dr. Cates outlined a scheme for the administrative control of the disease. Dealing with objections raised against compulsory notification, the lecturer said that it had been stated that notification was useless, because sufficient medical men and nurses could not at the present be obtained to provide treatment for measles patients. It must not be forgotten, however, that the health of the Army largely depended on the health of the civil population. Measles had already been the cause of a considerable amount of sickness among the troops, especially in those coming from isolated rural districts, and, apart from the risk of death, there was, from the military point of view, a serious danger in loss of efficiency.

Referring to the value of systematic home visitation by trained nurses, Dr. Cates urged that sanitary authorities should appoint an adequate staff of health visitors, each entrusted with the care of a small district, so that all work relating to infant and child welfare, the prevention of disease, and the removal of conditions of insanitation might be brought within the province of one official directly responsible to the medical officer of health.

There were five or six Government Departments directing the energies of sanitary authorities, education authorities, boards of guardians, insurance committees, and after-care committees innumerable, all attempting to cope with the same problem.

To-day, when economy was vital in public as well as in private life, it was regrettable that measures were not being taken to end the scandalous overlapping of the various agencies dealing with public health.

London and its Common Dangers

In the annual report of the Coroner for the City of London and Southwark, Dr. F. J. Waldo, some conclusions of general interest have been drawn from an analysis of the year's cases. Street accidents have increased in number since the darkening of all the City lights, and may thus be laid to the charge of the Zeppelin raiders. Simple carelessness on the part of pedestrians is frequently the sole cause of accident, but Dr. Waldo recommends the building of more street refuges, the detailing of a greater number of police for traffic duty, and he urges the need for more life-guards and fenders, particularly for the hind wheels of heavy motors. Attention is drawn to some of the

deficiencies of the Pharmacy and Poisons Act. The need for further restrictions concerning the sale of opium is detailed in a copy of the correspondence which he held upon the subject with the Lord President of the Privy Council. Dr. Waldo pointed out that since 1914 there have been two laudanums in the Pharmacopœia, and that although one drop of the weaker tincture has been known to kill a baby, yet the stronger tincture alone is included in the list of poisons. To remedy this the Privy Council in February last ruled that both tinctures should come under the same restrictions. Dr. Waldo emphasises the great importance of some adequate method of preserving unidentified bodies in the cases of criminal deaths, and recommends the general installation of the Herscher formalin apparatus which he has used with success for this purpose—the only apparatus of the kind as yet installed in connection with a coroner's court. Deaths from anæsthetics are decreasing in number, but, as usual, they have all but one been caused or accelerated by the use of chloroform or a chloroform mixture. A coroner's report becomes generally useful as well as interesting when it contains an analysis of avoidable deaths with suggestions for their prevention, and we commend Dr. Waldo's example to other coroners with similar opportunities.

The History of Digestion.

THE history of medical science is a record of the work of individual men possessed of an original turn of mind, of accurate power of observation, and of untiring energy. An illustration of this fact is to be found in an article entitled, "Digestion, an Historical Survey," by Dr. Raymond J. Cary published in a recent number of the *Johns Hopkins Hospital Bulletin*. The philosophers of the early days have been replaced by the practical experimentalists of to-day, as medical research has developed more and more upon materialistic lines. Numerous and varied are the theories which have found support since the time of the old Egyptian idea that digestion was the work of an indwelling demon, and indigestion but a symptom of his wrath, down to the present day. Four main theories, however, stand out, and for these men continued to contend vigorously until the latter half of the 18th century, when they were refuted by the experiments of Réaumur and Spallanzani. There was the theory of *coction*, or of food being digested by the innate heat of the body, the theory of *putrefaction*, that of *trituration*, deduced from the fact that the stomachs of turkeys can pound up glass balls, and the theory of *fermentation*. In the year 1782 Spallanzani published the results of numerous experiments performed upon a variety of animals as well as upon himself, and propounded the theory of chemical solution as the basis of digestion. From all this controversy the next real advance was made in 1833 by William Beaumont, who by his observation and experiments upon the gastric fistula of Alexis St. Martin proved the true physiology of gastric digestion, and led the way to our own knowledge of the present day.

Annual Election at the Royal College of Surgeons in Ireland.

THE annual election of President, Vice-President, and Council of the Royal College of Surgeons in Ireland takes place this week. Mr. William Taylor, at present Vice-President, is not opposed in his candidature for the Presidency. Mr. Taylor is Surgeon to the Meath Hospital, and one of the lead-

ing surgeons in Ireland. There are two candidates for the Vice-Presidency—Mr. John B. Story and Mr. R. Lane Joynt. Both have been members of the Council for many years. Mr. Story is M.B. and M.Ch. of Dublin University, and is a Fellow of the Royal College of Surgeons since 1880. He is Senior Surgeon to the Royal Victoria Eye and Ear Infirmary, and Professor of Ophthalmology in the School of the Royal College of Surgeons. He is a past President of the Irish Medical Association. He practises ophthalmology as a speciality. Mr. R. Lane Joynt is M.D. of Dublin University, and has been a Fellow of the Royal College of Surgeons since 1894. He is Surgeon to the Meath Hospital. He practises general surgery, and has taken a special interest in X-ray work and bone surgery.

The General Medical Council.

THE proceedings of the recent session of the General Medical Council contained little of interest to the general body of the profession. A number of penal cases dealing with the offence of "covering" the practice of an uncertified midwife were heard, and the Council showed the serious view it properly takes of such conduct. One practitioner was struck off the Register on the charge being proved against him, and others received grave warnings. We are glad to note that the Council decided to issue a special warning notice dealing with this class of professional misconduct. The Council had also the unpleasant duty of removing from the Register the name of a practitioner against whom the charge was proved of committing adultery with a lady whom he had attended professionally. This class of charge appears to be growing more frequent than in former years. Certain other names were removed from the Register on information reaching the Council of convictions in the public courts.

Suprarenal Insufficiency.

OUR Paris correspondent mentions that Professor Emile Sergent has published some interesting particulars in the last number of the *Bulletin of the Academy of Medicine*, concerning suprarenal insufficiency and the rôle of suprarenal opotherapy in army medicine and surgery. In his opinion, suprarenal insufficiency may be due to one or two great causes: either the suprarenal glands, hitherto quite healthy, are suddenly affected with acute lesions (infections, intoxications, hæmorrhage, etc.), or these glands, previously affected with some chronic lesions and performing their functions in a very unstable fashion, give way altogether under the influence of some new factor, such as over-fatigue, traumatism, etc., and this "suprarenal debility," as the author calls it, gives rise to serious symptoms. In the armies in the field the causes are very numerous. Enteric and paratyphoid infections have furnished many cases. Dr. Sergent has seen a great number of serious cases of enteric recover under treatment with subcutaneous injections of adrenalin, rather large doses of the latter being used. Several cases of choleric diarrhœa improved in the space of a few hours with the use of adrenalised saline solution and the administration of suprarenal extract. In cholera lesions of the suprarenal glands play a great rôle, and Naamé (of Tunis) has obtained splendid results with suprarenal opotherapy.

Opotherapy is applicable to the wounded and debilitated. In acute cases, at least 2 or 3 milligrammes of adrenalin must be used in injections (4 to 6 doses of $\frac{1}{2}$ a milligramme each), and besides this, one or two milligrammes should be given per os. The usual doses of 5 to 15 drops of the 1 in 1,000 solution, per os, give no results whatever.

War Psycho-Neuroses.

OUR Paris correspondent informs us that Prof. Grasset, who was put in charge of a special hospital for neurological cases at Montellier, has published an account of the cases he has had to deal with. He divided them into two groups—first, cases presenting organic lesions; second, cases suffering from psycho-neuroses.

Of the latter he has observed all the known varieties—sensori-motor, sensorio-motor, emotional and mental. According to the classic rule, it is not the most serious local wounds which give rise the most frequently to psycho-neuroses, but those accompanied with severe shock to the system—*e.g.*, the rush of air cause by the passage of shell, hurling the patient violently to a distance of three or four metres and even more, burying him sometimes more or less completely, or the bursting of a shell quite close to the patient, killing his comrades around him. Very often symptoms appear immediately. After a more or less prolonged loss of consciousness, the patient wakes up paralysed, with the sensation of having lost some of his limbs, or blind, deaf and dumb, or trembling and anguished. In other cases the psycho-neurotic phenomena appear more tardily, sometimes after cicatrization of the wound.

From the point of view of prognosis and treatment there are (a) light cases, recovery taking place without any special treatment; (b) medium; and (c) serious cases. The treatment in medium cases is the ordinary classic one: hot baths, hot shower baths, static electro-therapy, massage (simple and vibratory), mechano-therapy and re-education, tonic drugs and psychical treatment. It is advisable to send the patient away as early as possible with sick leave varying from one to three months. In serious cases the question is a much more difficult one: sick leave ought to be of two or three months, renewable as may be necessary. Patients who cannot be sent home should be treated in special hospitals for the purpose.

Aberdeen Public Health.

DR. MATTHEW HAY, Medical Officer of Health for the City of Aberdeen, has now issued his report for 1914, together with abbreviated reports for 1915. The total number of births registered during the year was 3,784, after correction for transfers from or to other districts. This gives a rate of 23.0 per 1,000 of population, as against 24.6 in the preceding year. Estimated in relation to married women between 15 and 45 years of age, the rate for legitimate children was 197 per 1,000 of such women. The proportion of males to females born during the year was 100.5 to 100, and is considerably lower than in 1914, when the ratio was 105 to 100. It has been said, Dr. Hay remarks, that during or after great wars the proportion of males increases. There were 380 illegitimate births during 1915, as against 377 in 1914—an increase of 3 only. He shows by detailed analysis of most exact method that illegitimacy has decreased since the war began. The number of marriages during the year was 1,878, equivalent to 11.3 per 1,000 of the population. This is by far the largest marriage rate ever recorded for the city since the commencement of civil registration. In 1914 the rate was 9.3. During 1915 there were 3,075 deaths. This is equivalent to a death-rate of 18.6 per 1,000 of population, and is the highest death-rate in any year since 1900. The excess of the birth-rate over the death-rate was 4.4, and is the lowest on record. There were 654 deaths of infants under one year of age, or 173 deaths per 1,000 births. This is an exceptionally high mortality, and compares unfavourably with the rate of 121 per 1,000 births in 1914, and with the average of 132 for the preceding ten years.

"Free" Hospital for Children at Sidmouth.

WE are asked to announce that Mrs. Cowley, of 94 St. Aldates, Oxford, is anxious to be of service to delicate children of needy naval and military officers and others whose incomes have been adversely affected by the present war. Mrs. Cowley offers to receive such children, between the ages of five and ten, for a period of four weeks and upwards as guests in her cottage at Sidmouth, South Devon. The house is situated four minutes from the sea; the sanitary arrangements are perfect. All costs of board and residence, and also of travelling, will be defrayed by the hostess. A competent matron and nurse are in charge of the Home, and give every care and attention to the children. Milk and eggs are supplied from a neighbouring farm.

Application for admission, with a doctor's recommendation, should be made to Mrs. Cowley, 94 St. Aldates, Oxford.

Medical Students in the United Kingdom.

THE President of the General Medical Council has sent us the following official return of the number of medical students in actual attendance in May, 1916, on courses of professional instruction at the various medical schools and approved teaching institutions:—

	Men.	Women.	Total.	Men from under 18.	Men outside U.K.
First year ...	1,422	636	2,058	489	102
Second year...	783	295	1,078	26	129
+Third year...	519	163	682	0	146
+Fourth year	1,078	145	1,223	0	186
Final year ...	922	140	1,062	0	115

+ A number of third-year students, who passed a professional examination at the end of the winter session, have been transferred to the fourth-year class by direction of the military authorities.

PERSONAL.

CAPT. NOEL ANTHONY COWARD, R.A.M.C., has been appointed Senior Sanitary Officer at headquarters at Havre. He was born in Leicester, and was educated at Stoneygate School, where he gained two scholarships of £80 at Blairlodge School, Scotland. There he won both classical prizes each year, and was made head prefect when 17 years old. Going to Edinburgh, he took the degree of M.B.C.M., with first-class honours. In 1913, Dr. Coward took his degree of M.D. at Edinburgh University, and his D.P.H. at Oxford.

FLEET-SURGEON JOHN FALCONER HALL, who, as was announced recently, has been appointed Assistant Director-General at the Admiralty, is a graduate of Aberdeen University. Dr. Hall, who attains to this distinctive appointment at the comparatively early age of 44, is a native of Etrick, and is a son of Mr. William Hall. He graduated M.B., C.M., in 1893, and two years later entered the medical service of the Royal Navy. He was promoted Fleet-Surgeon in November, 1904.

DR. AGNES ELLEN PORTER, M.D., D.P.H., who has been appointed assistant medical officer at Govan Combination Hospital, Merryflats, is one of the lady doctors who took part in the terrible retreat from Serbia, and only returned to this country in February last. Miss Porter had a distinguished college career at Edinburgh, where she graduated M.B., Ch.B. in 1906. She then proceeded to Strassburg University, and on returning after one year was appointed Research Scholar to the Royal Victoria Hospital for Consumption in Edinburgh. In 1909 she graduated M.D. and D.P.H. in Edinburgh, and in 1911 became Lister Research Scholar, Lister Institute, London. She was appointed a permanent school inspector to the Staffordshire County Council in 1915, but three months later proceeded to France as a bacteriologist. Soon afterwards she went to Serbia.

ORIGINAL PAPERS.

ON INJURIES TO PERIPHERAL NERVES AND THEIR SURGICAL TREATMENT.*

By FRANK C. PURSER, M.D., F.R.C.P.I., Major, R.A.M.C.,

Visiting Physician to Mercer's Hospital, Dublin.

A PROBLEM that is frequently before us, and one that is very perplexing, is that of deciding on the condition of some injured peripheral nerve and advising as to its treatment. It is the question on which I am asked for an opinion perhaps more often than on any other; and I acknowledge that almost every case presents some difficulty. No case requires more than these to be judged on its own merits and not by any rule of thumb. And after a most conscientious examination and consideration of the merits, subsequent developments often prove one to have been a bad prophet. Cases in which operation has been confidently recommended have improved surprisingly before it was undertaken, and others in which psychotherapy and time seemed all that was needed to effect perfect recovery, have consumed much of both with but disappointing results. This experience is pretty general. The difficulties lie largely in the number of the factors—many of them incalculable—which have to be taken into consideration; and to some extent in the examination of the patients, many of whom, to say the least of it, do not over-exert themselves in helping the examiner. By this communication to-night on the treatment of injured peripheral nerves I hope to start discussion, and to hear the experiences of others. I shall deal only with those aspects of the question which may be expected to interest the surgeon and physician alike.

In the first place, certain considerations are necessary in examining these cases.

When a mixed nerve is cut across there follows, of course, as a result, paralysis of sensation and of motion in the skin area and muscles supplied by that nerve. When a nerve is not wholly divided, but only partially, there are at least modifications of normal sensation and motion. Now, as a correct judgment of the condition and progress of an injured nerve depends on a just estimate of its loss of function, and especially on loss of sensibility in the area it supplies, I must delay a little in considering these preliminaries. Loss of sensation is two-fold; it is a loss in the cutaneous area and loss in the deeper structures, muscles, tendons, etc., supplied by the divided nerve. These two sorts of sensibility, the cutaneous or superficial and the deep, are distinct from one another. I emphasise this point, though I know it is well recognised theoretically, for I think that it is not so well recognised in practice, with the result that one reads some otherwise inexplicable accounts of very rapid return of nerve function after operation.

Cutaneous, or superficial, sensibility comprises the recognition of light touches as such and of their correct localisation. It allows one to recognise as separate two points when simultaneously applied—what has come to be known as the "compass" test. It comprises also the recognition of the painful sharpness of a pin-prick and the discrimination of temperatures even when they differ from one another by only a few degrees. Chief reliance is to be placed on the modifications of cutaneous sensibility.

Deep sensibility is less easily judged, and even in very complete injuries does not seem always to be absent. As far as our present enquiry goes, it concerns the recognition of pressure as a "touch" more or less heavy on the skin and subjacent structures, and a sense of pain when the pressure is severe. It will be readily understood from this that care must be taken in testing cutaneous sensibility not to stimulate deep sensibility. In testing the cutaneous sense of touch, only cotton wool must be used, or something equally light. Many use a finger tip, but no matter how delicately applied it is far too heavy. It causes deformity of the shape of the skin, and in so doing stimulates deep sensibility. Indeed, so much is the lightness of the object applied to be insisted on that I warn you that if you are meditating making a contribution to the study of sensation, it will not receive the respectful consideration of neurophysiologists unless the cotton wool used be of long staple like that used by jewellers. For a similar reason a wire pin, which is always blunt, should not be used for testing the sense of pain. Its application will often be acknowledged—but only as a deep touch—where a needle or a steel pin are not felt at all.

The local condition of the part to be tested must also be considered; it should be comfortably supported and pleasantly warm. And the patient himself should be comfortable and as willing as possible to give help. The man who wants his tea, or for some other reason resents your coming just when you do, will give much less accurate answers than he will give next day when the sun is shining and you are welcome. This reference to sunshine is not a mere pleasantry; there is no doubt that in any but crude testing a bright, fresh day conduces to answering quite appreciably more accurate than is obtainable on a damp, gloomy one. It is always wise to have as few spectators as possible.

When a mixed nerve, then, is divided in continuity—e.g., the median at the elbow—the sensory loss is a failure to recognise pressure over some of the flexor muscles of the forearm, and a loss of sense of touch of cotton wool, of the painfulness of a pin-prick, and of temperature in an area corresponding pretty accurately to the cutaneous distribution of the nerve as given in anatomical text-books. Motor power will be lost in the muscles whose branches of supply are given off distal to the level of section.

But this statement is not exactly the truth. Those stimuli which can be increased in degree without altering their character—the stimuli of pain by pricking and of temperature are wholly lost only over an area considerably less than that of the anatomical distribution of the nerve—so that, in the case of the median, as far as the palm is concerned, while all sense of touch is lost in the anatomical distribution of the nerve, recognition of severe pin-pricks and the extremest degrees of temperature are lost only in two fingers and a portion of the palm.

If the nerve is left divided the area where all sensibility is lost tends, for some reason, to shrink

* Paper read before the Surgical Section of the Royal Academy of Medicine in Ireland, April 7th, 1916.

—and not as we might think, to enlarge; and on the motor side the muscles waste and undergo changes (that are of clinical value) in their reactions to electricity. Later, if care be not taken to prevent it, the opponents of the paralysed muscles will shorten and contractions will occur, and the tissues in the area supplied may undergo trophic changes, and any trifling injury be long in healing.

But if the divided nerve be promptly sutured, and the wound heals without suppuration, recovery of power and of sensibility may be expected. Motor power, and with it some return of electrical excitability, may be hoped for in about nine months. Sensation is recovered more slowly. Between two and four months after suture the wholly anæsthetic area begins to shrink, and by the end of a year it is altogether responsive to pin-pricks and the extremest degrees of temperature. The lighter degrees of sensation—of touch, localisation and fine discrimination of temperature—are not so quick in returning. They take twelve to eighteen months. Last of all to return is the power of localising touches correctly and appreciating the simultaneous application of two points. And even when objectively sensation is wholly recovered there remains often for a year or two a subjective sense of "something different" in the affected hand—a numbness when stimulated, or a cold feeling.

All these times are only approximate and vary greatly in different cases. Recovery depends on many things besides the skill of the surgeon. The younger the patient and the nearer to the periphery the injury, and the more assiduous the post-operative treatment, the better the prognosis. Suppuration in the wound makes the outlook worse. An injury close to the spinal cord will recover slowly and imperfectly. And recovery depends on the nerve involved. In a nerve like the musculospiral it is better than in the ulnar, which supplies muscles of highly specialised action.

These short remarks will suffice to show what may be expected, at best, in, say, a glass-cut median nerve which has been sutured within a few hours of being injured. Unfortunately a wholly complete recovery is not the rule under even the most favourable circumstances. Some weakness or noticeable sensory defect remains. Less still can it be expected in the injuries inflicted in war, where we have to deal with men who are often run-down in health, whose wounds are septic, whose muscles and nerves have been of necessity left unattended to, and who are suffering from bruises, lacerations, fractures, and other extraneural complications. In these cases diagnosis and advice as to treatment are matters of particular difficulty; they take time to be arrived at and are rarely to be decided at a single examination.

Nerve injuries fall into two groups.

A group, numerically far the smaller, in which there is persistent total loss of function, and a group in which there is partial loss of function. A case in either group may be complicated by pain or by hyperæsthesia.

Total or partial loss of function may be due to complete or incomplete anatomical discontinuity of a nerve. Or they may be due to the pressure of exudate, hæmorrhage, fragment of a projectile, or of bone, etc., without any discernible anatomical lesion at all—a physiological discontinuity, and either total or partial discontinuity, but especially the latter, may be associated with pain or with hyperæsthesia. Let us consider the case of total loss of function.

It must be remembered that often as the result of a violent blow from a projectile a whole limb

may show both motor and sensory paralysis, and this without any discernible nerve lesion at all. This paralysis—asccribed to shock to the nerve—usually clears up rapidly and completely in a fortnight. One sees little of it at home. And, again, one must remember in making a diagnosis, that paralyzes of a functional or hysterical nature often occur with, or independently of, organic lesions of the peripheral nerves. It is often difficult enough to detect these, but the fact that the sensory loss is generally of a "glove" or "sock" distribution and does not correspond to a cutaneous area of any nerve or nerves, that there are no vaso-motor or trophic changes, and that the muscles react readily to Faradism will help to settle the question. And a careful enquiry into the circumstances of the injury and paralysis will also help. I have at present under treatment a rather extreme case which illustrates these points: a man with a healed but formidable looking scar about three inches below his right elbow joint. The scar surrounds about three-fifths of the forearm. The arm below the scar is very thin in comparison with the left arm, and there is total paralysis of the muscles supplied by the musculospiral and ulnar nerves, and almost complete paralysis of those supplied by the median. The man had been considered unfit for service on account of this paralysis of the arm, but on one case sheet there was a diagnosis of hysteria, and he was sent to me for further opinion. The muscles I found all reacted to Faradism readily. There was anæsthesia to touch and pain and temperature as high as the scar, and in the whole forearm, though certainly some cutaneous nerves must have escaped the original laceration. There was no vaso-motor change, and on making an enquiry into the history of the condition I found the scar was due to a crush by a cask edge ten years before he had enlisted, which was eight years ago. He had been in Flanders several months and had been sent home with a slight flesh wound in the contra-lateral shoulder. The paralysis came on suddenly on his receiving orders to join his regiment, orders which came at the same time as a domestic tragedy at home and news of the death of his brother in action abroad. I have seen several other cases where a shot through the forearm resulted in quite unequivocal functional paralysis, motor and sensory, which had been accepted as organic and reported accordingly.

But having made sure that the total loss of function is organic one must decide what to do. There is no sign or symptom that will enable one to decide whether the nerve is severed or involved in inflammatory tissue. The proper treatment in such a case seems to me to be to record exactly the sensory loss and the motor loss with the electrical reactions, but especially the sensory loss. Improvement in sensibility will be recognised long before improvement in motility, and on the change in sensory symptoms one can make some estimate as to the condition of the nerve. Should there be no change in six weeks or two months I think the nerve should be exposed. If it be found divided it must be sutured; if only compressed it must be freed. The outlook in the two cases is different. No very great recovery can be hoped for in secondary suture, and what does come is often rather long in coming. But much more may be expected both in completeness and rapidity of recovery in a nerve that is only compressed in a scar.

Cases of complete nerve division are very seldom associated with much pain. I have never seen such a case with any pain to speak of. But if it do occur it is in the same category as the nerves

in a painful amputation stump, and should be dealt with similarly.

It is of the utmost importance that the injured part should be well cared for while awaiting developments and after operation if that be undertaken. The essentials are that the limb should be rested and kept warm, and, most necessary of all, that the paralysed muscles should be kept constantly relaxed. Massage to these and passive movement of all joints to prevent contractures, and the application of any form of electricity to which the muscles may respond, are to be practised. If the muscles respond to no electric treatment its application is but waste of time. The effect of relaxation on paralysed muscles can sometimes be shown very well. I have seen cases of drop-wrist where no reasonable electrical stimulation gave any contraction in the extensors, till they had been relaxed by means of a splint for three or four days, when it was easy enough to induce one.

Now let us consider the much larger group of cases of partially divided nerves. In these cases symptoms vary from at most complete motor and sensory loss to no more than a subjective appreciation of abnormality. Often the motor loss seems, as far as one can compare the two, out of all proportion to the sensory loss. The sensory loss may be entirely overlooked in a superficial examination. But it is by it that one can judge more than by any other the progress of a case. The history of this injury will illustrate all these points. A man was hit by a bullet which fractured the humerus in the lower third and incidentally caused paralysis of the whole forearm and hand. The median and ulnar supplied areas rapidly recovered, but the muscles supplied by the musculospiral were obviously more deeply involved. The wound was a little septic at the time, and no operation was contemplated—this was three months after the injury. I was asked to see him, and I gathered that sensation was considered to be normal. When his splint was removed he had drop-wrist, and it was not easy to get any electrical reactions at all. I tested sensation, and he never failed to acknowledge the stimulus, and he made no remarks on the sensation it produced. I was going to write sensation down as perfect, but first I asked him as to comparison between the two hands—and he said it was "quite different" from the left hand. I then tested him with the compasses and tested his power of localisation. Both were very defective. One month afterwards the voluntary motor power was as absent as before, the wound had healed, and prospects of having to operate were distantly contemplated. But I found that although sensation was still subjectively "quite different" from the left hand power of appreciating two points as such had greatly improved, and localisation was perfect. Six weeks later very fair voluntary power had returned in the extensors, and this is steadily increasing. (Charts were shown illustrating this, and other sensory abnormalities.)

The return of power and sensation in a partially divided nerve is due to the release of the nerve from the pressure of hæmorrhages or inflammatory exudation. It is not due to the downgrowths of proximal axis cylinders and their fortuitous linking up with the distal remains of the nerve. Once inflammation has come to an end the loss of function becomes stationary. The question then arises whether to operate or to leave alone. The general considerations which I have enumerated will guide here as in the case of a wholly divided nerve. No complete cure can be looked for, and sometimes things are made worse by operation. If contractures have formed it is waste of time operating. Speaking generally, in the majority of cases it will be

found inadvisable to operate. (There is great luck in getting a good result, and the chance of making things worse is not negligible even with the most skilled. The patient will be advised not to risk a little power in his own hand for twice as much on the knees of the gods.)

But there are, I think, two very definite calls for operation. The first is where all inflammation has subsided and the patient is left with little or no power and fairly good sensibility. The risk of losing the sensibility may well be taken on even a chance of getting back power. And another definite indication for operation is the presence of severe pain or of hyperæsthesia. Pain is a much more common complication in partial nerve division than it is in cases of total division, and it is of a particularly, in the lay sense, "unnerving" kind. To rid the victim of it, it is well even to risk much motor loss. But the disabling factor of the pain must be weighed against the disablement of a paralysed nerve, and treatment on analgesic lines should be extensively tried before more radical measures. It might be well in some cases to consider the relief of pain by injecting alcohol into the sheath of a nerve—even of a mixed nerve. Its effects wear off in time, and by then perhaps the pain might be found to have worn off, too, and a fairly functioning nerve be left.

A propos of pain and hyperæsthesia, it is necessary to say a word about trophic disturbances. In my experience they are not very great, but in cases where there is much pain, in these the trophic changes have been more marked. Any procedure which will leave the affected area a sense of pain on pricking and even a crude appreciation of temperature will probably protect it against any gross trophic changes.

I now come to discuss what may be done at operation. It is a matter I feel shy of introducing, and I would not have had the presumption to do so at all had it not been hinted to me that my doing so would not be taken amiss.

I have spoken of the difficulties of deciding whether to operate or not, and have pointed them out rather than solved them. The difficulties of *technique* in operating are outside my personal experience, but I see that they are very great, and I have endless admiration for the skill that overcomes them.

There are some main guiding rules. One is that no operation should be undertaken unless the wound be healed, or at least aseptic. The chances of suturing giving any other result than a bulb of fibrous tissue would be none. Another rule is that a nerve must be handled with the extremity of gentleness. Indeed, it should never be caught up at all or held back on a hook, but lifted by its sheath. This is to avoid injury to the delicate nerve elements themselves and also to avoid hæmorrhage into the nerve or its sheath, for any exudation will lead to subsequent development of obstructing fibrous tissue. I have seen it done and often heard it stated that a man's leg may be lifted off the table by his exposed sciatic nerve—but the best results seem to be got when force is perfected in gentleness. And this gentleness must be extended to the dissection of scar tissue from around a nerve to avoid the exudation that may lead to more scar tissue. Some surgeons claim that they have spent up to four hours in such dissecting, and found the results justified the time and care spent. In German reports I have seen it stated that this dissection may be greatly helped by the injection into the nerve sheath of normal saline solution. Finally, in suturing a nerve the most exact apposition of the nerve fibres

in the divided ends must be aimed at. No other expedient is of any avail.

A question will arise in the numerous cases in which a spindle or bulb of fibrous tissue is found in the course of a nerve. Should it be removed or left? Neither eye nor finger can tell how much nerve fibre or how little traverses it. The loss of function found by clinical examination must be borne in mind, and if it be thought reasonable that resection and secondary suture will give better results let it be done. But no recognisable intact bundle of nerve fibres should ever be severed.

In resection the nerve should be cut with a razor. Scissors, be they never so sharp, crush the nerve fibres, and crushing is the surest way to stop their growth. The nerve should be cut till the fibrils are plainly visible, and then the two ends must be brought into the exactest apposition and under as little tension as possible—and the whole must be as dry as possible and protected from exudation as much as possible by a sleeve of vein, Cargile membrane, or layers of fat.

When a nerve is ready for suture it may be that, despite all stretching and flexing of joints to relax it, the ends cannot be brought into apposition. The prognosis is bad then. Of all the "bridges" that have been made between the ends, none offer so good a chance of success as the insertion of a piece of sensory nerve from the patient himself. And no "bridge" of nerve over four inches in length can be expected to function. I have heard of much longer "bridges" being successfully laid. But four inches is on the long side. Perhaps next best is a "bridge" taken from an amputated limb. A nerve from a rabbit or other animal is useless. And there is no unequivocal evidence that guides like a portion of vein, decalcified bone, or strands of catgut ever lead to any recovery of continuity.

Should approximation of the ends be impossible, and bridging also fail, some result may be hoped for by grafting one nerve into another. This is done by suturing an end into a notch made in a sound nerve. This operation is common enough as regards the facial and spinal accessory nerves or the facial and hypoglossal, it is less common in the case of nerves in the limbs. It has been done, however, successfully in the case of the median and ulnar. The first fully successful case was one where the median was divided in its length and one portion joined with the peripheral end of the accidentally divided musculospiral. At the end of two years and three months there was good power in all the extensor muscles of the wrist and fingers, but not of the thumb.

In these cases of nerve anastomosis there must be a sorting out and re-arrangement for transmission of impulses in the spinal cord. At first, as in the case of the spinal accessory and facial anastomosis there is an associated movement, but in the course of time, as the cord accommodates itself, this becomes dissociated. A rather more recent form of anastomosis is the insertion into the trunk of a sound nerve of both the proximal and peripheral ends of the divided nerve. Here the spinal cord has to make no rearrangements. Impulses will pass to it and from it by the normal segmental roots. The main line of the uninjured nerve has double traffic over part of its length. I have seen no detailed accounts of this method, but preliminary reports are favourable.

In isolating a "flap" of sound nerve care must be taken not to take too much. Apparently one-quarter or one-third of the nerve can be divided without noticeable loss of function—it is this fact that makes nerve anastomosis possible at all. But a nerve must not be notched close to a branch, for there the fibres going to make up the branch are

segregated into one bundle and this bundle may be divided wholly in the raising of the flap.

I have, perhaps, not been as optimistic about the chances of surgery in these injuries as would be complimentary at a surgical meeting. This is not from want of appreciation of surgery, but it is from an appreciation of the very real difficulties the surgeon has to face. It is difficult enough to deal with the nerve when it is found; it is sometimes more difficult still to find it. I believe the possibilities of surgery are increasing in this field; but I think if neuroplasty is to have the success of, say, abdominal surgery, that even the simplest operation will have to be looked on as of necessity a lengthy business, so that the greatest patience and care may be exercised in securing complete isolation and accurate apposition of the nerve-ends, with the minimum of tension and the minimum of handling.

THE PROGNOSTIC SIGNIFICANCE OF A COPIOUS RASH IN TYPHOID AND SIMILAR INFECTIONS.

By H. GOUGEROT, M.D.,

Professeur Agrégé at the Faculty of Medicine of Paris.

MANY years ago, when I was a young house physician in the Paris hospitals, I was impressed by the case of a young woman suffering from typhoid fever which had been ushered in by marked symptoms with a profuse eruption of rose-coloured spots, because, to my astonishment, the disease ran a short, mild course, whereas I had anticipated some sort of parallelism between the gravity of the disease and the intensity of the eruption. My chief, Dr. Troisier, told me he had remarked several instances of the same kind, adding that he had heard the same thing commented upon by his seniors. Since that time, as it is my practice to scrutinise closely the skin of all my patients, I have on various occasions met with similar appearances, especially during the winter of 1914-15 in our ambulance at the front, which happened, for the time being, to be set aside for the treatment of cases of typhoid.

These cases were noted in conjunction with my colleagues, Dr. Monod, senior physician, and Drs. Bribon, Cavillier, Perrin and Ducuing, and will be published in due course with all necessary details along with several series of interesting cases which came under our observation during that period. Bacteriological examinations were too few under the circumstances, so that we are obliged to deal in one and the same group with infections of the typhoid type, whether due to Eberth's bacillus or to paratyphoids. This, however, is not of much importance, seeing that we are discussing a clinical symptom common to all infections of this group produced by organisms slightly different, it may be, but not admitting of distinction clinically.

Two series of contrary, but mutually completing, facts led us to infer that a copious eruption of pink spots was a sign of good augury. As a matter of fact, in all the serious cases in which life was threatened the eruption was discrete or, when profuse, as sometimes happened, it faded and disappeared while the infection became graver and more protracted. On the other hand, all the cases of typhoid accompanied by numerous spots proved to be mild. It is to be noted that the greatest care must be devoted to the diagnosis of the pink spots, because this is often rather difficult on an uncareful skin, and it is easy to confuse them with the lesions of osteofolliculitis and commonplace infections. The elements should be kept under observation for several days before expressing an opinion.

Sometimes the infection was mild and the

symptoms not very pronounced: G had 102.4° F. on admission, and the temperature did not rise above 102.7° lasting only 21 days. M. had 102.7° on admission, and it did not rise above 103.8°, the fever lasting 19 days. P. had 102.4° on admission, did not rise above 103.3° (save for one day, 105.6°), and the fever lasted 21 days, with a slight relapse lasting four days, with a maximum of 102.2°. B. had 104° on admission, and did not exceed 104.2° and the fever only lasted 22 days. B. had 102.9° on admission, did not rise above 103.3°, and the fever lasted 23 days.

In some instances the course was still shorter, in spite of a rather sharp onset. B. had 103.3° on admission, did not rise above 103.3°, and the fever only lasted 14 days. R. B. had 104.4° on admission, did not rise above 104.9, and the fever only lasted 15 days.

The spots were numerous, often generalised, sometimes presenting the classical appearances, sometimes prominent and soft, sometimes papular. They came out about the eighth day (P.), the tenth day (G.), the twelfth day (M.), or still later, ushering in defervescence; on the eighteenth day in B. Even in these mild forms the relationship between the height of the fever and the number of spots is often striking.

Sometimes the attack of typhoid looks serious, grave even, with high fever on the patient's admission. The pink spots soon made their appearance in large numbers, whereupon the infection assumes a milder aspect and is cut short, the appearance of the eruption coinciding with the favourable turn—indeed, seeming to usher it in.

B. came in with a bad attack and a temperature of 104.2°, which suddenly subsided, returning to normal 16 days after admission on the appearance of the eruption.

C. had a sharp attack with a temperature of 105.1°, which soon fell, and the temperature returned to normal twelve days after the appearance of the eruption.

P. had a bad attack, with 104.2°, and here again the temperature fell to normal 18 days after the eruption appeared. The eruption came out on the ninth day of the disease, became more abundant during the next few days, and remained so down to the 18th day, diminishing only when the curve fell.

The case of B. was particularly well marked. Admitted on the ninth day with a temperature of 104° and a grave general state, it was noted that the rash was general, and so incomplete defervescence took place on the 11-12th day. Thereupon the rash "went in," and the disease relapsed, lasting 25 days.

Sometimes the typhoid is mild but protracted, and the rash keeps coming out all the time, showing, as it were, that although protracted the attack is a mild one.

Sometimes—pretty frequently, in fact—the attack runs its usual course, grave, moderate, or mild. Apart from the early rash, we may get fresh eruptive elements later on which seem to usher in the end of the disease.

We must, of course, be careful not to generalise too rashly. We get mild attacks of typhoid without a copious generalised eruption, but all the cases under my notice in which there has been a copious, generalised rash have proved to be mild—at any rate as long as the eruption remained copious. We also get grave cases which become mild without any copious generalised rash. There may also be cases of grave typhoid with an abundant rash at the onset, but in the cases under our observation the turn for the worse was accompanied by the subsidence of the better-marked papular elements, so that the disappearance of the spots with continuance of the eruption is a bad prognostic sign.

What explanation can be offered of this occurrence, which is in opposition to what one might have anticipated? We are naturally tempted to assume that a copious eruption testifies to intense infection, but these cases seem to be strictly comparable with other eruptive fevers, especially measles. In the latter disease it is a common belief that a gloomy prognosis attaches to cases of severe measles in which the rash "goes in" or "comes out" badly. Directly the eruption comes out well, the attack of measles becomes less threatening.

As far back as 1781, Borsieri suggested that in these cases the skin acted as an emunctory, and I am favourably inclined to the view that the integument plays a defensive part, endeavouring to fix and excrete microbial toxins and the products of auto-intoxication. I think, too, that in all probability the skin not only fixes the toxins, but burns them up. The inflammatory reaction in the skin, characterised by erythema, heat, etc., testifies to this process of combustion.

But why, in this defensive rôle, does the skin sometimes succeed, as shown by an intense eruption? How is it that it sometimes fails, as shown by an ill-defined, imperfect eruption? I believe that this is merely a question of the resistance of the organism. If the infection be too violent the organism is unable to react; the poisons come to the surface, but the skin lacks the energy to destroy them, so that the non-destroyed poisons invade the viscera, so to speak, by metastasis. Should the organism recover power enough to react *via* the skin, or if the activity of the skin be artificially stimulated by mustard baths or what not, the cutaneous defence again comes into action, as shown by the appearance of the eruption, the poisons are burned up, and the disease assumes a less grave aspect.

Defective resistance on the part of the organism is the principal cause of the ill-defined or "gone in" eruptions, but it seems possible that other causes may hinder the cutaneous reaction, as, for instance, the existence of a visceral inflammation (inflammation of the lungs, for example) thus preventing destruction of the poisons in the skin and rendering the disease *pro tanto* graver.

The same explanation applies in respect of the pink spots in typhoid fever: each pink spot is due to a small microbial embolus of living or dead microbes, conveyed thither by the blood. It represents a struggle, an effort on the part of the organism to kill the living parasite, to dissolve the dead microbes, and to destroy the poisons they elaborate which are set free by the dissolution of the microbes. The slight inflammatory reaction—redness, œdema, etc.—testifies to this struggle. The more pronounced the reaction, the more active the struggle, and the more efficacious the defence. It is therefore easy to grasp the fact that in an organism weakened by grave infection, reacting badly, or not strong enough to react at all, the microbial emboli fail to set up this reaction of defence in the skin, so that we get few pink spots. On the contrary, an organism attacked by a mild infection and actively resistant, reacts sharply, and every microbial embolus is the seat of an inflammatory struggle; in other words, the eruption is general. In a patient who, at the onset, displays numerous pink spots, aggravation of the infection diminishes his resistance and therefore its power of reaction; then the pink spots subside, and subsequent cutaneous emboli fail to set up any reaction. When in a grave attack the patient recovers greater defensive power as he approaches the period of defervescence, then the cutaneous reaction is shown by the late appearance of the pink spots.

Clinical observation and pathogenic considerations both suggest that the pink spots are evidence

of effectual defence on the part of the organism—afford, indeed, a sort of measure of the organic resistance in such wise that a copious eruption comports a favourable prognosis.

THE THYROID AND PARATHYROID GLANDS.

By IVO GEIKIE COBB, M.D., M.R.C.S.,
L.R.C.P.,

Late Assistant to Out-patient Physician, the Middlesex Hospital, etc.

In a former article (*a*) we briefly reviewed the present place of the endocrine glands in medicine, and suggested some practical points in connection with hormone therapy. We now propose to discuss in a little more detail the more important of the ductless glands, laying emphasis upon the known results of administration of the extracts of these glands, and the signs pointing to deficiency or excess of the secretion.

Naturally, the thyroid gland first deserves our attention, and for several reasons. First, more is known of its characteristics, secretion, functions, and disorders; secondly, it takes a particularly important place in medicine on account of the frequency with which disorders of its functions are encountered; and, finally, of all the ductless glands whose secretions have been utilised in the form of extracts for oral or hypodermic injections, the thyroid gland has given the best and most astonishing results. From the moment when G. R. Murray first published the results achieved by administering thyroid extract to a patient suffering from myxœdema (October 10th, 1891), great interest has been aroused in the practice of organo-therapy, an interest which Brown-Séquard's previous statements on the results of feeding with testicular extract had failed to arouse.

In 1890 Vassale in Italy and Gley in France experimented with injections of thyroid extract to animals who had been deprived of their thyroids, and demonstrated that these animals could be kept alive by such injections. This was followed shortly afterwards by the application of this discovery to therapeutics, when Murray treated his case of myxœdema by thyroid extracts and established that this condition could be cured by these means. Previous to this date, Gull and Ord in England had investigated myxœdema, and Köcher had described a condition following the removal of the thyroid which, from the similarity of its symptom complex, was shown to be identical with the spontaneous condition already named myxœdema.

As far back as 1859, Schiff discovered the fatal result which accrued from the total removal of this gland, and later when Köcher described "cachexia strumipriva," or the condition of post-operative myxœdema which followed so many of his early operations for goitre, this fact attracted wide attention. Schiff and subsequent observers also discovered that transplanting the gland beneath the skin relieved the symptoms. Unfortunately, it has now been shown that an implanted gland is very liable to absorption, and thus to lose its utility.

These researches had established the fact that removal of the thyroid gland was followed by a train of symptoms which constituted the condition named "myxœdema." (*b*) A fresh factor then arose, on account of the discovery of two pairs of small glands, situated on either side of, and deep to the lateral lobes of the thyroid, which received the name of "parathyroids." It was maintained by some

authorities that the symptoms which followed the removal of the thyroid gland were due to the removal of these small glands, and in support of this theory, it was adduced that while removal of the thyroid alone was not usually fatal, removal of both thyroid and parathyroids proved rapidly fatal. On the other hand some observers maintained that it was impossible to remove the parathyroids without also interfering with the integrity of the thyroid. Forsyth concludes, from the result of his investigations that the parathyroids have no connection with tetany, and in this he is in opposition to most observers. We shall have more to say about this when we are dealing with the functions of the parathyroids.

HISTOLOGY AND PHYSIOLOGY OF THE THYROID GLAND.

The thyroid gland belongs to the group of ductless glands—that is to say, its secretion is poured into the blood-stream direct and not by means of a duct. It is situated in the neck, and consists of two lobes, one on each side of the trachea, extending upwards to the thyroid cartilage covering its inferior cornu and part of its body. Joining these two lobes is the isthmus. The gland is surrounded by a capsule, and is composed of vesicles lined with cylindrical or cubical cells. These vesicles contain the typical colloid material, iodothyronin, which is composed of iodine in combination with an active principle which has the characters of a globulin. Its recognition we owe to Baumann of Freiburg, who discovered its existence in 1896. Herbivores possess it in abundance, as most vegetables contain iodine. The weight of the gland varies between 32 and 60 grms.; it is larger in females than in males, and undergoes changes in size at the menstrual periods and at such times as puberty and the climacteric; it is liable to swell under marked excitement and during emotional strain.

The colloid with which the vesicles are filled plays an important part in general bodily metabolism. In man there is nearly always sufficient for it to be discovered analytically (in normal health), but Wells states that the actual amount varies with the locality. It is scanty in young children and in parenchymatous goitre; unusually high in exophthalmic goitre. It has been suggested that an important function of the thyroid gland is to control the iodine metabolism of the body.

Now, what are the results of removal of the gland in man? When we come to review the knowledge which experimental physiology has given us we are at first rather bewildered by the apparent contradiction which faces us. Early observations upon the effects which followed removal of the gland in animals showed that, in carnivora, the effects were very severe and often fatal, tetany supervening and the animal dying from cachexia. In herbivora, however, the results of such an operation were often exceedingly slight, and were confined to a slight cachexia, but sometimes a rapidly fatal result ensued. The first inference to be drawn from this was that a meat diet was the important factor which accounted for the difference between the effects in carnivorous and herbivorous animals. Gley, however, showed that the explanation was quite different, and he proved that the parathyroids (one pair, now usually known as the "external parathyroids") were responsible for the wide difference in the results. He demonstrated that these small glands were so situated in carnivora, that when the thyroid was removed, the parathyroids were also removed; whereas, in herbivora they were as habitually left behind. When the operations were made identical the results were approximated.

(a) MEDICAL PRESS AND CIRCULAR, May 24th, 1916.

(b) This name came into existence on account of the believed existence of excess of mucin in the subcutaneous tissues in these cases.

This originated the view now widely held, which regards the nervous symptoms following removal as attributable to the loss of the parathyroids; the effects of thyroid removal alone being, in the young, an analogous condition to cretinism, in the adult a cachectic condition. Indeed, in the young animal, the effects of thyroid extirpation are much more marked than in the adult animal. A few of the changes produced are striking. As we have already said, a cretinoid condition results, with delayed ossification of epiphyses, diminished development of the bones of the skull, protuberant abdomen, relaxation of the ligaments of the spinal column, and sexual infantilism. Alterations in the growth of the hair are observed in some species, and, most interesting of all, an extensive atheromatous degeneration of the aorta is found, which bears out the hypothesis that the function of this gland is concerned with calcium metabolism. Horsley had surmised previously to this discovery that many of the features of thyroid inadequacy resembled those which characterise senile decay.

Where thyroid secretion is excessive, we know that there is increased calcium leaving the body; and, in those patients exhibiting deficiency of thyroid, we may assume that increase of the calcium salts at the disposal of the metabolism results in an atheroma—a laying down of this substance in the walls of the arteries.

After thyroid extirpation there are several changes which deserve special mention. Firstly, there is a marked retardation of metabolism in general, nitrogenous metabolism is greatly reduced, fat metabolism is likewise diminished, as the tendency to the deposition of fat in myxœdema shows. As opposed to this, however, the animal without a thyroid exhibits excessive tolerance to carbohydrates: it can take abnormally large amounts without suffering from glycosuria. The reduction in the metabolic exchanges naturally diminishes heat production, and this point is of interest from the practical standpoint, human beings with deficient thyroid secretion being much more susceptible to the cold, and suffering increased discomfort in the winter months. As opposed to this, patients with Graves's disease rarely suffer any inconvenience from cold, but feel the heat of the summer months to be almost insupportable. As is well known, they are nervous and restless, and the increased tissue wastage produces a rapid loss of flesh, and in some cases actual emaciation.

Turning now to the parathyroids, which it will be remembered are of more recent discovery, we find that there are two pairs of these glands, situated, as we have already said, in close proximity to the lateral lobes of the thyroid gland itself. In structure, they bear some resemblance to this latter gland, resembling it, however, more in its embryonic characteristics. They are formed of columns of granular epithelium cells, and show a very vascular connective tissue between these. It has been stated that, if these glands are left when the thyroid has been removed, they undergo a marked hypertrophy.

To Sandström belongs the credit of first accurately describing these little glands. His view was that they were in reality embryonic rests of thyroid tissue proper. At the present time, although our knowledge of their functions has advanced somewhat, much of the knowledge we possess may be described as more speculative than proven. MacCallum came to the conclusion that they controlled in some way the calcium metabolism of the body. Calcium moderates the activity of nerve cells, therefore when the secretion of the parathyroids is deficient, and calcium is lost from the nerve cells, the patient will suffer from an exaggeration of nervous excita-

bility. This corresponds to the surmises as to the causation of the nervous symptoms which are manifested when the thyroid has been extirpated. In support of this view, the administration of extracts of the parathyroid glands in cases of tetany has been proved to be efficacious in controlling the convulsions. It will be remembered that tetany is a prominent symptom after extirpation operations in animals. Likewise the administration of calcium salts will control the symptoms of tetany.

Opposed to the views just quoted, some observers believe that the parathyroids are portions of the true thyroid gland, that they have become separated from the gland itself, or that they secrete the same colloid, although they have not as yet formed vesicles; or that they develop into normal thyroid tissue, intermediate types having been noticed.

It is stated that if all four parathyroids are removed, the animal succumbs rapidly, no matter whether the thyroid is left intact or not. If one parathyroid be left, death does not usually ensue, although tetany may be brought on. It has also been said that changes in these glands are very common in cases of tetany in children, in pregnant women, and in osteomalacia (a disease associated with defective calcium metabolism). This would seem to be supported by the beneficial effects of calcium administered by the mouth (it would tend to replace the excessive loss of calcium owing to the defective parathyroid secretion).

With the few facts at our disposal, and the many speculative theories based thereon, it is natural that many diseases should have been attributed to an abnormality of these glands. To take one example, it has been suggested that paralysis agitans may be due to disease of the parathyroid glands, but unfortunately it does not appear to benefit by the exhibition of extracts of these glands. This is, of course, not tantamount to a refutation of this theory, as it may mean that the extract undergoes changes during its passage through the body, which rob it of its natural properties, so that it is unable to replace the normal secretion which should be delivered into the blood-stream. The only instance which, so far as I am aware, has been published in which parathyroid extract appears to have been absolutely successful, and to have been, if one may use the expression, specific, is described by Hertz in the *Practitioner* for January, 1915, in an article on the parathyroids. Briefly, this case was a man of middle age, who had suffered from an enlargement of the thyroid gland, and had undergone an operation in which the greater part of it was removed. He remained well for two years, and then suddenly became very restless, tremulous, and developed fibrillary tremors and other signs which closely resembled Graves' disease. His hair ceased to grow, he became impotent, his bowels were loose, and his weight decreased very rapidly.

No treatment was of much avail, and the administration of dry thyroid gland aggravated the symptoms. He was given dry ox parathyroid by the mouth, and from that day he began to improve, became stronger, increased very markedly in weight, and returned to work. Not until he had been taking the parathyroid gland for six months did his sexual powers return. Hertz concludes the account of this very interesting case: "His weight in February, 1914, had risen to 189 lbs.; he felt perfectly well and strong and no trace of nervousness remained, although he was working very hard."

Here, apparently, was a case in which the secretion of the parathyroids was deficient, and where its administration by the mouth was able to replace the normal secretion.

If this latter surmise be correct, it would seem that it is possible for an analogous treatment to

that of myxœdema to be initiated if only we could arrive at an accurate diagnosis. It would support the school which believes in the separate functioning of the thyroid and parathyroid; and might eventually show us where we are lacking in the treatment of exophthalmic goitre. It is certain that the removal of part of the thyroid does not cure this disease, although it may ameliorate the symptoms for a variable time. If the nervous symptoms are due to excess of thyroid secretion, then removal of part of the gland should counteract the excess. But if this group of the many symptoms of Graves's disease owes its existence to an abnormality of the parathyroids, we must alter our surgical treatment of this disease.

On the other hand, we have yet to study the views of that school which has returned to Gley's original belief: that the parathyroids are part of the thyroid gland, that they are an embryonic and partly-developed thyroid tissue. In support of this view, it is stated that post-operative tetany is greatly benefited by administering thyroid gland by the mouth, and that pure parathyroid, even in larger amounts, has not given the same results. It would appear from this that tetany owes its origin to deficient thyroid, and not necessarily deficient parathyroid; although the ordinary sheep's thyroid gland contains parathyroid substance.

This school, therefore, regards the parathyroids as part of the thyroid, and not separate structures; their function would be similar, and, it follows from this hypothesis, that the diseases which have been tentatively attributed to the parathyroids (mainly on account of the similarity which their symptom-complexes bear to those produced experimentally) must in reality owe their origin to the thyroid—assuming that they are in any way connected with this gland. This is comforting, as it narrows the field of inquiry—it leaves us one set of riddles to solve instead of two. But we must admit that this view is not widely accepted, mainly on account of the many small facts which have been collecting—albeit slowly—to show us that the parathyroids are undeserving of neglect.

We must now leave the subject of the parathyroid glands, and, before concluding this article, briefly review the theories which endeavour to account for the work of the normal thyroid gland. What is the function of the thyroid? Does it govern metabolism? Is it a "vital antiseptic"? Or is it concerned with growth alone? The only way in which we can attempt an answer to these questions is to give some few facts and more theories dealing with the function of this gland.

Firstly, then, the thyroid gland possesses the peculiar property—peculiar in the sense that it is not shared, so far as we know, by the other endocrine glands—of being able to store its secretion. This is proven by the fact that in cases where the gland has atrophied or been removed, its secretion can be replaced by artificial ingestion. We quite naturally turn to the colloid as being the stored-up secretion, and, indeed, we are justified in so doing, as there is evidence to show that this substance arises as droplets in the epithelial cells lining the vesicles (Dale). Again, this secretion contains a relatively large percentage of iodine (.2 per cent.), and on this fact, or partly on this fact, has arisen the theory that the thyroid has a phagocytic or anti-toxic action. In young animals, however, the iodine content is very small, and in adult animals it appears to be a direct ratio to the iodine content of the food. On the other hand, there is no reason to suppose that the power of the body to resist intoxication is raised when iodine or the iodides are given by the mouth; although Hunt found that young thyroids had some power to raise the re-

sistance to a particular substance (acetonitrile), which power ran more or less roughly parallel to the iodine-content.

In this connection, the action of iodides upon gummata is of interest; and, as pointed out by Rendle Short, the beneficial action of these drugs is in reality due to the increased action of the thyroid which is engendered by the administration. He says: "I have found thyroid extract quite as effectual as iodide of potassium in healing tertiary syphilitic ulcers." In speaking of the action of iodides on gummata and atheroma, he says: "In cases of myxœdema arterio-sclerosis is early and intense. The same is true in animals after removal of the thyroid. Eiselsberg gives a number of very convincing photographs of intense atheroma of the aorta in his cretin lambs in which the thyroid had been removed in early life. In the second place, thyroid extract has a wonderful power over young connective tissue, as is seen by the way in which it absorbs the subcutaneous thickening of myxœdema and cretinism. It is not surprising, therefore, that it should be able to deal also with gummata and atheroma. (a)

The theory of toxin-neutralisation states that the secretion of the thyroid has the power to neutralise toxins which find their way into the blood-stream. It goes on to maintain that these toxins (of albuminoid nature) are absorbed from the alimentary canal and undergo iodisation in the thyroid by means of its secretion. It will be remembered that Lane maintains that atrophy of the thyroid gland is one of the features of chronic intestinal stasis. Is this the result of overwork? Hardly, for overwork produces hypertrophy, not atrophy; and yet, if the symptoms and signs attributed to intestinal stasis owe their origin to toxæmia, and the thyroid is the neutraliser, then (to reconcile the two theories), the thyroid should be enlarged, *not* atrophied. In other words it should be overworked, not idle.

We know, however, several facts of importance about the thyroid to balance this tangle of theories. Firstly, we know that a train of symptoms follows its deficiency or absence, whether produced experimentally or arising spontaneously, and that these symptoms will yield to thyroid feeding. The results of an extirpation operation in young animals differ only slightly from the condition which we know as cretinism, while the adult analogy of this we encounter as myxœdema.

Thyroid is therefore concerned with the growth of bone; with the development of the body; and with a normal circulation. It has been suggested that the reason why the colloid is scanty in the young is that it is used as rapidly as it can be manufactured by the gland. As we shall see when discussing thyroid deficiency, the clinical pictures of the slighter forms of inadequacy require discrimination to discover, and are as yet not sufficiently definite for their wide acceptance. But the above facts lend themselves to further investigation.

Again, in the adult, there can be now little doubt that absence or diminution of the secretion produces—or helps to produce—a condition of secondary anæmia. Whether this argues any direct connection with the hæmatopoietic system, we are unable at present to say. That the thyroid is a direct circulatory stimulant there can be little doubt; for the slow pulse, cold extremities, sluggish circulation, and deficient action of the sweat-glands in sub-myxœdema are very well recognised.

The interaction of the thyroid with the other ductless glands is at present unknown, but the future will probably show that the relation between

(a) "The Newer Physiology in Surgical and General Practice." By A. Rendle Short. Third edition. Pp. 82-83.

the thyroid and some of the other endocrinic glands, notably the spleen, is a close one.

We must here leave the discussion of the thyroid and its small neighbours, realising only too well that many blanks still remain to be filled up—which further light on this most difficult subject can alone do. (b)

"AVIATOR'S SICKNESS."

By JOHN KNOTT, M.A., M.D., F.R.C.S.I.

THE discussion of one of the associations of aviation in your columns of May 3rd—an issue of THE MEDICAL PRESS AND CIRCULAR now permanently associated in my memory with the very effective hold-up of postal functions produced by our explosive Sinn Fein upheaval—has recalled to my recollection the existence of a French book which first saw the light somewhere about 1880, and of which a copy is at present buried away "somewhere in" the disorderly contents of my chaotic library. This prognostic volume dealt, and with clairvoyant anticipation, with a large proportion of the creations and achievements of the (then "coming") "Twentieth Century." It was very liberally illustrated, and the author—evidently a genius of the Jules Verne school—has surely good reason, if still living, to feel proud of the productions of the inspiration afforded by his prophetic gift. For there the reader was treated, among other delights, to views of sundry and manifold flying machines: bird-shaped, fish-shaped, fly-shaped, cigar-shaped; engaged in conveying passengers across land, and over sea: on business trips, holiday and honeymoon excursions, touring pilgrimages, migratory movements, journeys of emigration, mercantile transmission, postal transit and delivery, etc., etc., with interjected halts at central metropolitan stations, and punctuated delivery of amatory epistles at upper bedroom windows, in fashionable town areas and at aristocratic country mansions. Such prophetic projection of the *idea*—in the literal sense of this pregnant term—on the cinema screen of mental vision has surely proved the source of the inspiration which has so successfully produced a teeming harvest of "modern" miracles of science and conquest of nature.

There can be no serious question, as I believe, of the front-rank position of the wireless, the cinema, and the air machine among the items of the vast congeries of gifts which have been conferred by science upon humanity during the past few years, as majestic and enduring monuments of the triumphal achievement secured by the cosmopolitan leaders of the contemporary progressive march of intellect. No other age of the world's record has been known to produce, within corresponding limits of time, anything comparable to the expanding conquest of Nature's mysteries and obstacles that has been effected during the expired decade and a half of this our own wonderful twentieth century. And nothing worthy of mentioning in the same breath with the three above-named can now be brought into the court of skilled historic scrutiny—with the probable exceptions of the Röntgen rays and the radium emanations. These, too, have been found to levy their respective tolls of personal injury—on the cutaneous integrity of their votaries. They have also revealed the association of discounting drawbacks in the culture and application of their respective, apparently almost miraculous, properties and powers. And while the former has proved productive of a good deal of clinical neglect of the culture of the powers

of skilled audition, trained visual conception, and the proverbial *tactus eruditus*—to say nothing of the collateral revelations procurable by the evidence of smell and taste—the mysterious properties of the latter have lent themselves all too readily to the criminal pretensions of the licensed quack, and the woeful gullibility of a gaping and suffering public, always on the vain look-out for the advent of a messianic remedy possessed of the gift of redemption from all previously incurable infirmities of the flesh. But the hour has not yet come, and humanity has still to bear its continuously modified burden, while unceasingly goaded onwards by the stimuli of mental and physical tension and torture; some old and others new! The most dismal of the facts recalled by such reflections is, of course, presented by the present inter-relationship of the leading communities of our old-world civilisation—all of which are just now eagerly occupied in the concentration of all their capitalised knowledge and intellectual culture, with all their available mechanical and specialised professional skill, on the sole purpose and methods of mutual destruction. A consuming fever of thought and action!—how consoling it would be if we could only dare to hope that the concluding crisis would be succeeded by permanent immunity.

One of the inevitable pathological excrescences of the (very practical) science of aviation was bound to germinate in the minds of the amateur physiologists of limited education who elected to discuss the all-important question of the maintenance of the equilibrium in this connection. The characteristically Gallic suggestion of the function of the semicircular canals in furnishing the sense of direction and capability of maintenance of equilibrium could not fail to bear fruit here. The curiously diagrammatic arrangements of those unique constituents of the complicated auditory apparatus have, times without number, produced quite a mesmeric effect on the eagerly inquiring medical student of the second year curriculum. (I can answer for one.) Their arrangement is so strongly reminiscent of that of the co-ordinates of Descartes, with the aid of which the semi-inspired founder of modern algebraic geometry located the position and relative direction of a point in space. But the gilt veneering has now been long since worn off, and the crude metallic fact remains that there exists no truly logical evidence of such location of a function—of which the actual centre is necessarily placed in the nerve cells of the auditory area of the cerebral cortex—any more than of the validity of the location (by the aforementioned Descartes) of the human soul in the *conarium (glandula pinealis)*: because the soul must have a material organ; this organ must be a part of the brain, the organ of intellect; it must also be *azygos* in arrangement, central in position, and unique. As well might one have argued that the very peculiar *snail-shell* form of the adjacent *cochlea* provided the innate *laziness* which a trans-Atlantic philosopher has pronounced the first instinct of humanity, and that the sugar-tongs outline of the forceps of Reil is the cerebral locus of man's taste of sweetness. Other enthusiastic inquirers have used some of the above arguments for location of the soul: in the *corpus callosum*, in the *septum lucidum*, in the cavity of the fifth ventricle itself, in the sub-arachnoid space, in the heart, in the blood, in the animal spirits, etc. But Van Helmont, "the Father of Modern Chemistry," went one better and at least 90° lower, for he actually located the immortal principle of life at the pylorus! (Was he a martyr to dyspepsia?)

(b) The next article in this series deals with "Graves' Disease."

Did he receive a solar-plexus knock-out thrust among his school and college experiences? Or was it that he was really, if not nominally, of German ancestry?)

Then the unlucky semi-circular canals have been saddled with the loss of power of maintenance of verticality after Tommy Burns's lightning operation. An eminent metropolitan surgeon was made to say so, after Tommy's triumph, in an "interview" which displayed more mastery of pugilistic than of physiological science. But the barefooted young ruffian of an Irish village seemed always to know (? by instinct) the efficacy of "a clout at the butt o' the lug" with the threat of which he bullied the smaller boy. So did that proverbially skilful operator, Jack Ketch, when he located his sinistral knot at that part of his patient's surface! And the very obvious *rationale* is that the brain rests there, gravitationally, on a dense unyielding bone, with next to no fluid pad beneath; while the position also affords the best leverage for a disturbing side-thrust, which throws the delicate machinery quite as *anaesthetically* out of functional commission as if it had been subjected to the lacerating Haughtonian procedure.

MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the end of my last letter I said I would to-day describe the attempt that was made in 1858 to provide the profession with what may be called a complete Legal Constitution and to explain at least its partial failure. By the Act of 1858 the General Medical Council was set up with the powers it still wields. Its functions were the supervision and control of medical education and examinations and the establishment of a Register of qualified practitioners. It was also endowed with certain disciplinary powers over qualified practitioners. The Council, during its career of over fifty years, has been the subject of much criticism: some perhaps just, but largely put forth under mistaken impressions, the Council's activities being strictly confined within narrow statutory limitations. I write of the Council only in regard to its connection with my main theme. By its reforms in education and examinations the Council has raised enormously the real qualification of the young medical man, and it is safe to say that on admission he is more fully prepared for his calling than is the neophyte of any other learned profession. By the extent and difficulty of the examinations there have been weeded out the classes of idlers and men of low intellectual capacity. Those entering the medical profession nowadays know that they are devoting themselves to an arduous occupation which, with extremely rare exceptions, will provide them with neither wealth nor fame nor anything beyond the wants of a frugal man—one prepared to die in harness. After the passage of the preliminary educational examination the curriculum occupies at least five years. No statistics are available, but a large percentage of practitioners possess degrees in arts or science of one or other University, besides their medical qualifications. A very large percentage also take up much higher degrees than are obligatory. This is a most important point, and may be emphasised by an illus-

tration within my own recent experience. Some short time ago a vacancy occurred in the staff of a local cottage hospital. Three candidates presented themselves. Of these one was a medical and surgical graduate of London; the second of Cambridge, and the third was F.R.C.S. Eng. These men were all obscure country practitioners. Their qualifications were unknown to me—their friend, and, of course, were absolutely unknown to the public. They had always intended to devote themselves to general practice. Love of their profession and desire to make themselves masters of it had made them sacrifice the time and labour called for. Men like these are to be found throughout the country, in town and rural districts. Their qualities are, of course, known to their brethren, and they bring their skill, and especially their surgical help, to many cases which formerly must have been injured or perhaps killed by removal to some distant hospital. The existence of this large number of highly accomplished men within the body of the profession is mainly due to the work of the General Medical Council. It is necessary to note for the purposes of my argument that a great number of medical men are engaged in scientific research of the utmost value to the public, but which brings to them neither honour nor adequate remuneration. Another great army of doctors, public medical officers of various grades, are out as a corps of hygienic missionaries, and whilst improving the public health are practically taking the bread out of the mouths of their profession, albeit with its hearty consent. I have never been a practitioner of medicine, and for the last twenty-five years have been a mere looker-on. I cannot, therefore, be fairly charged with boasting about myself when I describe my profession as a noble calling. It contains at least a far greater proportion of men leading lives of self-sacrifice than is to be found in any other calling, not excepting the ministry of religion. It might have been thought that a profession like this—a great body of men of proved character and high scientific attainments—would have had some voice and authority in all matters of State in which they were even remotely connected. It is, however, a deplorable fact that the profession has virtually no political power or authority of any kind, even in cases in which their counsel is absolutely necessary if the welfare of the State is to be effectually safeguarded. It is only necessary to mention the Insurance Act to make the medical reader realise this fact. It can be further illustrated by the history of the failure of the profession to bring about amendments of the Medical Act of 1858, which should render to the public the protection which the preamble of the Act promised. The failure of the profession to establish any political power has been mainly due to the default of the British Medical Association. I repeat that I impute no blame for this state of things to any officer or party within the Association; it seems due to some inherent faults in the constitution of the Association or defects in its administrative machinery. It has had the power in recent times to gather the opinions and voice the demands of from 20,000 to 30,000 men—its members—selected from what is best in the profession, and it has entirely failed.

I must, with your permission, put off to my next letter discussion of the flaws in the Act of 1858, to which I have here merely alluded.

I am, Sir, yours truly,
HENRY SEWILL.

The Old Rosery,
Earlswood Common.
June 1st.

"SINAPIS" AND THE B.M.A.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Pope says, "To err is human, to forgive divine." So, "Sinapis," even though you are not a god, you can for a brief moment assume divinity and pardon my human errors. As this is my final appearance, it is my duty to report progress. In the issue of the MEDICAL PRESS AND CIRCULAR, May 3rd, you inform your readers that some years ago you resigned your membership of the B.M.A. Your nature is kindly, so far we agree; that you take an interest in the B.M.A. is apparent to everybody. It looks rather like "the call of the old love"! You cannot forget her. You *appear* to be angry in order to be kind. To calm your anger, think of Athenodorus, who, when taking his leave of Cæsar, said, "Remember, Cæsar, whenever you are angry to say or do nothing before you have repeated the four-and-twenty letters to yourself"—which you will note means repeating B.M.A. eight times.

Now, you have declared your desire that the B.M.A. shall be an entirely scientific body. Medico-political matters can look after themselves until such time when some competent organisation is born, trained, and has reached man's estate; but, unfortunately, the Government, in dealing with medical matters, tarries not, but prepares and delivers its attacks upon the plan of hustle and bustle.

Now, "Sinapis," pray do not fear the B.M.A., but make the B.M.A. fear you. Rejoin the Association, become a Representative, and expound your views. In conclusion, sleep over Canning's words and ponder—

"And finds with keen, discriminating sight
Black's not so black, nor white so *very* white."

I am, Sir, yours truly,

S. J. ROSS.

Monkhams, Bedford.

June 6th, 1916.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—*"Moritur et oritur."* I note that Dr. Stephen John Ross, of Monkhams, Bedford, is once more giving signs of life in your columns: on this occasion in the cause of the B.M.A., by a research into the theological psychology of "Sinapis," which, nevertheless, has brought him fame "at the Periphery."

On his return to activity, Dr. Ross might fairly consider his obligations to his labours, yet incomplete. Your readers may remember that as a new member of the Council of the Medical Defence Union, and as the Council's champion, he debouched in your issues of September 15th and 29th last, but so far has failed to face the matter-of-fact questions in this connection put to him in your issues of September 22nd and October 13th last.

Let us hope that Dr. Ross will prove of greater utility in the B.M.A. than he appears to have been in the Medical Defence Union.

I am, Sir, yours truly,

DENNIS VINRACE.

Gower Street, London.

June 3rd, 1916.

We have received the following for publication:—
TREASURY GRANT OF 2s. 6d.

DEAR SIR (OR MADAM),—Have you observed that the Insurance Commissioners have recently adopted the system of arbitrarily imposing fines for alleged breaches of the conditions relating to the Treasury grant of 2s. 6d. per insured person per annum?

This sum is annually voted by Parliament to make up the total capitation fee of 7s. According to the practitioners' agreements, for this grant to be paid, it is stipulated that:—

- (1) Records shall be kept of attendances.
- (2) Certificates shall be issued in compliance with the Rules.
- (3) A prescribed standard of treatment shall be maintained.

As the Commissioners have been persistently inflicting penalties for the alleged breach of these conditions, the Council of the Panel Medico-Political Union sought the opinion of the eminent lawyer, Mr. F. Gore-Browne, K.C. He has stated that the letter of the law requires the "damages" or "loss" sustained in respect of an alleged breach of contract to be proved and to be such as would be assessed by the Courts, and that it is, in his opinion, illegal for the Commissioners to fix an arbitrary penalty.

In view of the fact that the Commissioners have instructed Insurance Committees to withhold sums ranging from £50 to £2 for insufficient or incorrect record cards, the legality of the position is a matter of considerable importance to the panel profession. The danger to which those practitioners were exposed who have been penalised may be your danger in the near future.

The question of the desirability of testing the Commissioners' right to impose arbitrary fines will be discussed at the annual general meeting of the Panel Medico-Political Union, which will be held on Wednesday, June 7th, 1916, at 3.30 p.m., at the Connaught Rooms, Great Queen Street, Kingsway, London, W.C. You are cordially invited to attend and to express an opinion on the subject.

Yours truly,

A. WELPLY,
General Secretary.

Panel Medico-Political Union,
47 Fleet Street, London, E.C.

May 29th, 1916.

P.S.—If you are not already a member of the Union, you will be asked not to vote upon the other business on the agenda paper. Full particulars as to membership will be gladly furnished on application.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, APRIL 7TH, 1916.

Mr. ALEX. BLAYNEY in the Chair.

REMARKS ON INJURIES TO PERIPHERAL NERVES.

MAJOR F. C. PURSER read a paper on this subject, which will be found under the heading of "Original Papers" on page 511.

BULLET INJURIES OF NERVES AND THEIR TREATMENT.

Mr. W. S. HAUGHTON read a paper on the above subject. He dealt chiefly with the mechanical effects of high velocity bullets striking the tissues, and described the different types of lesion that resulted in the nerves in the neighbourhood of wounds.

MISS LOUISA EDWARDS, of Brighton, left £250 each to the Alexandra Hospital, Brighton, and Royal Sussex County Hospital; £50 each to the Brighton and Hove Hospital for Women, Brighton, Hove and Sussex Ear and Throat Hospital, and the Sussex Eye Hospital.

SPECIAL REPORTS.**GENERAL MEDICAL COUNCIL.**

ONE HUNDRED AND THIRD SESSION.

THIRD DAY, THURSDAY, MAY 25TH, 1916.

The President, Sir DONALD MACALISTER, in the Chair.

The minutes of the last meeting were taken as read, and confirmed.

The PRESIDENT announced that the Acting Registrar had been directed to restore to the *Medical Register* the name of Mr. Casper Denis Downing.

The Council proceeded to the resumed hearing of the case of Mr. Daniel Evans Powell, adjourned from the previous day, whereupon Mr. Powell's solicitor stated that neither Mr. Curtis Bennett nor Mr. J. A. C. Keeves, counsel for the defence, would be able to be present at that stage; but that he (Mr. P. W. Butcher) would be prepared to conduct the defence, and preferred that the case should now proceed.

In the temporary absence of Mr. Powell, however, the Council decided to proceed with other business.

The Council proceeded to the consideration of the case of Henry William West, registered as of 352 Vernon Road, Old Basford, Notts, M.R.C.S.Eng. 1892, L.R.C.P.Lond. 1892, who had been summoned to appear before the Council on Wednesday, May 24th, 1916, at 3 p.m., on the following charge:—

"That being a registered medical practitioner you were on November 1st, 1915, convicted at the City of Nottingham Assizes of feloniously killing and slaying one Harriet Ann Hodgkinson, and sentenced to seven years' penal servitude."

Mr. West was called, but did not answer to his summons, nor was he represented by counsel or solicitor.

The Acting Registrar having read the notice, the Council's solicitor laid the facts before the Council.

He read the certificate of conviction which he put in, and also read extracts from a newspaper report of the trial.

The Legal Assessor read Mr. West's letter in reply to the solicitor's notice of inquiry.

The Council deliberated on the case *in camera*.

Strangers having been re-admitted, the PRESIDENT announced the judgment of the Council as follows:—

Mr. Harper: I have to announce to you that Henry William West has been proved to have been convicted of the felony alleged against him in the notice of inquiry, and that the Registrar has been directed to erase his name from the *Medical Register*.

Mr. Powell having arrived the Council proceeded to the consideration adjourned from Wednesday, May 24th, 1916, of the case of Daniel Evans Powell, registered as of 101 High Street, Tooting, S.W., M.B., C.M. 1894, U.Glasg.

Mr. Powell attended in answer to his notice, accompanied by Mr. Philip Webster Butcher, of the firm of Messrs. Webster Butcher and Sons, solicitors.

The Central Midwives Board, the complainants, were represented by Mr. Julius Bertram, their solicitor.

Sir Francis Champneys, President of the Central Midwives Board, withdrew, and the PRESIDENT announced that he would take no part in the proceedings.

The Council's solicitor having read the notice, Mr. BERTRAM proceeded to open his case.

He informed the Council that as he had been unable to procure any shorthand report of the proceedings against Mrs. J. W., at Bow Street, and had been refused access by the Public Health Committee of the Wandsworth Borough Council to the notifications of births, he had difficulty in tendering first-hand evidence, but proposed to put in evidence as to the proceedings in the form of the notes and oral testimony of the solicitor who conducted the prosecution.

Mr. BUTCHER intimated that he took no exception to the proposal.

Mr. BERTRAM called Mr. George William Duncan, Secretary of the Central Midwives Board, as a witness, and examined him as to the accuracy of his declaration. Mr. Duncan was cross-examined by Mr. BUTCHER, and answered a question put to him by a member through the Chair.

Mr. BERTRAM called Mr. John James Greenwood, solicitor in the solicitor's department of the Council of the administrative County of London, as a witness, and examined him as to the accuracy of his declaration.

Mr. Greenwood was cross-examined by Mr. BUTCHER.

Mr. BERTRAM called Miss A. E. T— as a witness, and examined her as to the truth of the accuracy of her declaration, which she desired to correct in some particulars.

She was cross-examined by Mr. BUTCHER, and answered a question put to her by a member through the Chair.

Mr. BERTRAM called Miss E. D— as a witness, and examined her as to the facts of her confinement. She was cross-examined by Mr. BUTCHER, and answered questions put to her by the Legal Assessor, and by members of the Council through the Chair.

Mr. BERTRAM called Mrs. Lily May Best and examined her as a witness. She was cross-examined by Mr. BUTCHER, and re-examined by Mr. BERTRAM.

Mr. Bertram called Mr. Edwin Samuel Wood, one of the inspectors, under the Public Health Acts, of the London County Council, and examined him as to the notifications of the births set forth in Mr. Duncan's declaration. He was cross-examined by Mr. BUTCHER, and re-examined by Mr. BERTRAM, and answered questions put to him by members of the Council through the Chair.

This closed the case for the complainants. Mr. BUTCHER then called Mr. Powell as a witness on his own behalf, and examined him. He was cross-examined by Mr. BERTRAM, and answered questions put to him by the Legal Assessor. He also answered questions put to him by members of the Council through the Chair.

Mr. BUTCHER then addressed the Council on behalf of Mr. Powell, and Mr. BERTRAM did not desire to address the Council in reply.

Strangers having been re-admitted after the Council had deliberated *in camera*, the PRESIDENT announced the decision of the Council as follows:—

Mr. Daniel Evans Powell: The Council has carefully considered the charge made against you, which, in effect, was that you had by your assistance knowingly enabled a woman not certified under the Midwives Act, 1902, to attend women in childbirth under cover or pretence that such women were attended, or to be attended by you, or by her under your direction, thereby enabling her to practise as if she were certified.

The facts alleged against you in the charge the Council has found to be proved.

The Council takes a very grave view, from the public point of view, of the danger which arises from medical practitioners lending their names for such a purpose and "covering" the practice of unqualified or uncertified women, under whatever pretext they practise midwifery or otherwise attend and treat women in labour. But in order to give you an opportunity of reconsidering your position in relation to this matter, the Council has postponed judgment in your case till the next Session, in November, of which you will receive due notice. You will then be required to attend, and to produce testimony from your professional brethren as to your character and conduct in the interval.

The Council proceeded to the consideration of the case of James Andrew Baird Thompson, registered as of 37, Bolina Road, South Bermondsey, London, S.E., M.B., C.M. 1877, M.D. 1879, U.Glasg., who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you

abused your position by committing adultery with a Mrs. Grigson, whom and whose husband and child you had attended professionally, which adultery you were found to have committed by the verdict of a jury given at the trial of the case of Grigson v. Grigson and Thompson in the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, on October 20th, 1915, and in which the decree was made absolute on May 8th, 1916.

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

Dr. Thompson was present in answer to his notice; he was not accompanied by counsel or solicitor.

The Acting Registrar having read the notice, the Council's solicitor, in the absence of a complainant, placed the facts before the Council.

He read the decree *nisi* and the decree absolute, certified copies of which he put in. He read a passage from a letter of a solicitor who had been acting for Dr. Thompson, and asked if the latter still adhered to the same line of defence, viz., that at the time of the adultery professional relations did not exist.

Dr. Thompson replied that he did adhere to this defence, and that he denied adultery prior to September 10th, 1913, on which date and on September 13th he admitted that misconduct had taken place.

The Council's solicitor then read extracts from the shorthand writers' notes of the proceedings in the Divorce Court.

Dr. Thompson called Mrs. M. E. Grigson, and examined her as a witness. During the examination of the witness, 6 o'clock approached, and the hearing was adjourned to the next day.

It was then agreed that the nominations of the Branch Councils for the various committees be adopted:—

EXAMINATION COMMITTEE.

The following members had been nominated by:—

The English Branch Council: Dr. Taylor, Dr. Saundby, Dr. Caton.

The Scottish Branch Council: Dr. Russell, Dr. Knox, Dr. Norman Walker.

The Irish Branch Council: Sir John Moore, Sir Arthur Chance, Dr. Kidd.

EDUCATION COMMITTEE.

The following members had been nominated by:—

The English Branch Council: Dr. Norman Moore, Sir G. Philipson, Sir Francis Champneys.

The Scottish Branch Council: Dr. Mackay, Mr. Hodsdon, Dr. Knox.

The Irish Branch Council: Sir Arthur Chance, Sir Bertram Windle, Dr. Little.

PUBLIC HEALTH COMMITTEE.

The following members had been nominated by:—

The English Branch Council: Dr. Newsholme, Dr. Latimer, Mr. Verrall.

The Scottish Branch Council: Mr. Littlejohn, Dr. Cash, Dr. McVail.

The Irish Branch Council: Sir John Moore, Dr. Magennis, Dr. Kidd.

The Council then adjourned.

FOURTH DAY, FRIDAY, MAY 26TH, 1916.

The President, Sir DONALD MACALISTER, in the Chair.

The minutes of the last meeting were taken as read, and confirmed.

The Council resumed the consideration, adjourned from Thursday, May 25th, 1916, of the case of James Andrew Baird Thompson, registered as of 37 Bolina Road, South Bermondsey, London, S.E., M.B., C.M. 1877, M.D. 1879, U.Glasg.

Dr. Thompson resumed his examination in chief of Mrs. M. E. Grigson, and put in a letter which had been written on May 24th, 1916, to her by her husband with reference to her return to him.

Mrs. Grigson was cross-examined by the Council's solicitor, and answered questions put to her from

the Chair, and by a member through the Chair, and was re-examined by Dr. Thompson. She also answered questions put to her by the Legal Assessor.

Dr. Thompson then gave evidence on his own behalf. He was cross-examined by the Council's solicitor, and answered questions put to him through the Chair.

Dr. Thompson addressed the Council on his own behalf, and put in certain letters and testimonials.

The Council's solicitor briefly replied. This closed the case.

Strangers having been re-admitted after the Council had deliberated *in camera*, the PRESIDENT announced its judgment as follows:—

Dr. Thompson: I have to inform you that the Council have judged you to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase your name from the *Medical Register*.

The Council proceeded to the consideration of the case of William Joseph Ryan, registered as care of the British Medical Association, 429 Strand, W.C., L.R.C.P.Edin. 1888, L.R.C.S.Edin. 1888, L.F.P.S. Glasg. 1888, who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you were convicted of the following misdemeanours, viz.:—

"(1) On February 27th, 1914, at the Lambeth Police Court of being drunk and incapable, and fined 3s.

"(2) On April 23rd, 1914, at the Tower Bridge Police Court of being drunk and disorderly, and directed to pay the costs—viz., the doctor's fee of 7s. 6d.

"(3) On April 7th, 1915, at the Tower Bridge Police Court of being drunk and disorderly, and fined 5s. or five days.

"(4) On February 22nd, 1916, at the Bow Street Police Court of being drunk and incapable, and fined 10s."

Mr. Ryan was not present in answer to his notice, nor was he represented by counsel or solicitor.

The Acting Registrar having read the notice, the Council's solicitor, in the absence of a complainant, laid the facts before the Council. He proved the service of the notice by registered post, but could not prove that the notice had been received. The Council's solicitor read the certificates of conviction which he put in.

Strangers, by direction from the Chair, withdrew, in order that the Council might *in camera* consider a point of procedure.

Strangers having been re-admitted, the Council's solicitor read correspondence which had passed between Mr. Ryan and the Registrar and Acting Registrar in regard to his convictions.

This closed the case.

Strangers having been re-admitted after the Council had deliberated *in camera*, the PRESIDENT announced its judgment as follows:—

I have to announce that William Joseph Ryan having been proved to have been convicted of the misdemeanours alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the *Medical Register*.

The Council proceeded to the consideration of the charge against William Bonallo, in regard to whom the Dental Committee had found the following facts:—

"The said William Bonallo was registered in the *Dentists' Register* on December 31st, 1878, as 'in practice on July 22nd, 1878,' and his address in the *Register* for the current year is Cramlington Hall, Cramlington, Northumberland.

"The said William Bonallo did not attend. Service of the notice of inquiry was proved by the solicitor."

The Committee find that the following facts were established by the evidence:—

"That on November 2nd, 1915, the said William Bonallo was convicted at the Northumberland Assizes of feloniously using a certain instrument with intent

to procure miscarriage, and was sentenced to three years' penal servitude.

"The evidence before the Committee consisted of the certified copy of the said conviction and the *Newcastle Daily Chronicle* of November 4th, 1915."

Mr. Bonallo did not attend in answer to his notice, nor was he represented by counsel or solicitor.

The Acting Registrar read the report.

The Council then deliberated on the case *in camera*. Strangers having been re-admitted, the PRESIDENT announced its judgment as follows:—

I have to announce that William Bonallo having been proved to have been guilty of the felony alleged against him in the notice of inquiry the Council has directed the Registrar to erase his name from the *Dentists' Register*.

The Council arranged to meet at 11 a.m. next day (Saturday), to adjourn at 1 p.m., and to resume at 2 p.m., rising at 4 p.m.

The Council then adjourned.

FIFTH DAY, SATURDAY, MAY 27TH, 1916.

The President, Sir DONALD MACALISTER, in the Chair.

The Council considered the case of John Thomas Dickie, registered as of 37 Lauriston Place, Edinburgh, L.R.C.P.Edin. 1881, L.R.C.S.Edin. 1881, who had been summoned to appear before the Council on Wednesday, May 24th, 1916, at 3 pm., on the following charge:—

"That being a registered medical practitioner you were on May 4th, 1916, convicted in the High Court of Justiciary on two separate charges of culpable homicide by using instruments in the bodies of each of two pregnant women and causing them to abort, and were sentenced to five years' penal servitude."

The conviction having been proved it was ordered that the name of John Thomas Dickie be erased from the *Medical Register*.

Motion by Sir FRANCIS CHAMPNEYS, seconded by Mr. PYE-SMITH:—

"That it be remitted to the President, in consultation with the Legal Advisers of the Council, to draw up, for submission to the Council, a warning notice with regard to the 'covering' by medical practitioners of uncertified women practising as midwives."

A discussion followed, in which Dr. NEWSHOLME, Sir H. MORRIS, Drs. TAYLOR and NORMAN WALKER, Sir JOHN MOORE, the PRESIDENT and Dr. LANGLEY BROWNE took part, an important point, *inter alia*, brought forward being that many practitioners do not understand the meaning of covering in these cases; the position of midwives in Ireland and in Scotland being also discussed. Sir FRANCIS CHAMPNEYS having answered and pointed out that most probably the unqualified women tend to propagate puerperal fever, the motion was carried.

The report from the Finance Committee was next received, entered on the minutes and approved. Proposed by Mr. TOMES, seconded by Sir H. MORRIS.

The Council then went into *camera* to consider a recommendation by the Finance Committee; also to receive and report from the Emergency Committee.

The report of the Education Committee was, on the proposition of Dr. MACKAY, received and entered on the minutes, and after a short discussion adopted. The report was as follows:—

On November 4th, 1915, the following resolution was adopted by the General Medical Council:—

"That it be remitted to the Education Committee, with the addition for this purpose of Dr. McVail and Dr. Newsholme, to report to the next meeting of Council on the education of medical students in the ethical relationships of medical practitioners to the State, to their patients and to each other, and that the Committee have power to make such inquiries on the subject as it deems advisable."

A letter addressed by the Acting Registrar to all the teaching bodies elicited the information that in most cases the subject is dealt with as part of the regular work in the courses of forensic medicine and public health, to some extent also in other classes, and

occasionally in special lectures. In a number of instances, however, no regular instruction has hitherto been given.

The Committee are of opinion that it is advisable that the subject should not be neglected in the education of the medical student; but they recognise that the special arrangements adopted for conveying the instruction may naturally vary among the different bodies. They propose, therefore, that a general recommendation dealing with the teaching of medical ethics be added to the resolution of the General Medical Council in regard to professional education as adopted on June 6th, 1912 (Minutes, Vol. XLIX., pp. 81 and 300), as follows, viz.:—"Instruction should be given, in the courses of Forensic Medicine and Public Health, or otherwise, on the duties which devolve upon practitioners in their relationship to the State, and upon the generally recognised rules of medical ethics. Attention should be called to all explanatory notices on these subjects issued by the General Medical Council."

The report from the Dental Education and Examination Committee was received and entered on the minutes, and after being discussed was approved, proposed by Mr. TOMES, seconded by Sir H. MORRIS.

The Committee had received a report from the University of St. Andrews for the recognition of a dental diploma, which recognition the Committee recommended. An application had been received from Mr. H. H. Elkam, now working as a dental surgeon at 15th General Hospital, Alexandria, for registration on the *Dentists' Register*. He possesses the licence of the Dental Board of Adelaide. The Council agreed that this should be granted.—The report dealt with the question of modifications in the curriculum, such as bringing it down to four years; also with expense, some members asserting that the dental curriculum cost more than the medical. The Committee in the report stated that they agreed in attributing any shortage there may be mainly to the inadequacy of the Dentists Act, also in considering that the preliminary examination should be the same for dental as well as for medical students. With regard to the best method for protecting the public from being deceived by unqualified persons, the Committee regret in their report that they do not see any means which the Council could adopt short of attempting to procure an amendment of the Dentists Act. A motion was therefore proposed to the Council "That the Lord President be informed of the urgent necessity of the public being able to distinguish between qualified and unqualified dentists." This motion was carried *nem. con.*

The report from the Examination Committee in regard to various matters relating to the Apothecaries' Hall, Dublin, and to the Assistant Surgeon Branch of the Indian Medical Service was approved.

The following report from the Public Health Committee was received and entered on the minutes, proposed by Sir JOHN MOORE, seconded by Dr. LATIMER:—"The Public Health Committee report that at their meeting on Tuesday, May 23rd, 1916, the replies of the licensing bodies to a circular letter calling their attention to the figures in the statistical table presented to the Council by the Committee on November 4th, 1915, was considered, and that it was resolved to report to the Council that the further consideration of the statistics relating to the examinations for qualifications in Public Health would be deferred until the next session of the Council."

The report from the Pharmacopœia Committee was received, entered on the minutes, and approved.

The report from the Students' Registration Committee was also received, entered on the minutes, and approved.

Mr. King was re-elected General Registrar.

On the proposition of Dr. NORMAN MOORE, a vote of thanks to the Chairman was carried by acclamation.

The Council then rose.

A BED has been endowed at the Ilford Emergency Hospital with £750 collected among passengers who escaped injury in the railway collision at Ilford on New Year's Day of last year.

THE KING'S BIRTHDAY HONOURS.

THE list of honours conferred by the King on the occasion of His Majesty's birthday includes the following:—

Privy Councillor.—Christopher Addison, Esq., M.P., M.D.

Knights.—Francis Mark Farmer, Esq., Armand Marc Ruffer, Esq. M.D., Professor Nestor Tirard, M.D.

K.C.M.G.—Walter Baldwin Spencer, Esq., C.M.G., Professor of Biology, University of Melbourne, and Director of the National Museum of Natural History, Geology, and Ethnology, Melbourne.

C.M.G.—Frederick Montizambert, Esq., M.D., I.S.O., Director-General of Public Health, Canada.

C.I.E.—Major Frederick Norman White, M.D., Indian Medical Service, Assistant Director-General, Indian Medical Service (Sanitary).

C.I.E. (additional) for meritorious service in connection with the war.—Captain Alexander Gillilan Johnson Macllwaine, Royal Army Medical Corps, Embarkation Medical Officer, Bombay.

Kaiser-I-Hind Gold Medal.—Henry Martyn Newton, Esq., F.R.C.S., of the Church of Scotland Mission at Jalalpur Jatan, in the Gujrat District, Punjab; Robert George Robson, Esq., M.A., M.D., C.M., Chairman of the Municipal Committee of Ajmer; the Rev. Peter Cullen, M.D., Brigade-Surg. Lieut.-Colonel, Indian Medical Service (retired), of Jubbulpore, Central Provinces.

Order of the Bath.—To be Additional Member of the Military Division of the Third Class, or Companions, of the said Most Honourable Order: Fleet Surgeon Ernest Courtney Lomas, D.S.O., M.B., F.R.C.S.Ed., R.N. To be Additional Member of the Civil Division of the Third Class, or Companions, of the said Most Honourable Order: Surg.-General John Jeffreys Dennis, M.D., R.N.; Col. Alfred Percy Blenkinsop, Assistant Director-General, Army Medical Service; Major Percy Samuel Lelean, Royal Army Medical Corps, Assistant Professor, Royal Army Medical College.

Royal Victorian Order.—To be Members of the Fourth Class: Noel Dean Bardswell, Esq., M.D., Medical Superintendent, King Edward VII.'s Sanatorium, Midhurst, Sussex; Frederick Stanley Hewett, Esq., M.D., Surgeon-Apothecary to His Majesty the King.

MEDICAL AWARDS FOR BRAVERY.

A SUPPLEMENT to the *London Gazette*, published on May 30th, contains the following awards:—

D.S.O.

His Majesty the King has been graciously pleased to approve of the appointment of the undermentioned officer to be Companion of the Distinguished Service Order in recognition of his gallantry and devotion to duty on the field:—

Temp. Capt. Thomas Lewis Ingram, R.A.M.C. (attached 1st Bn. Shrops. L.I.), for conspicuous gallantry and devotion to duty. He collected and attended to the wounded under very heavy fire, and set a splendid example. Since the commencement of the war he has been conspicuous on all occasions for his personal bravery.

MILITARY CROSS.

His Majesty the King has been graciously pleased to confer the Military Cross on the undermentioned officers, in recognition of their gallantry and devotion to duty in the field:—

Capt. James Couper Brash, M.B., 10th Fd. Amb., R.A.M.C. (Spec. Res.), for conspicuous gallantry and devotion to duty. He went to an artillery dug-out which had received a direct hit, and, assisted by

two men, extracted the wounded and administered first aid under heavy shell fire.

Capt. Henry Percival Hart, M.B., R.A.M.C., for conspicuous gallantry and devotion to duty when, although himself wounded, he went out, dressed, and brought into safety the wounded under heavy shell fire.

Temp. Capt. Philip Randal Woodhouse, M.B., R.A.M.C. (attd. 1st Bn. I. Gds.), for conspicuous gallantry and devotion to duty. He tended the wounded under heavy shell fire, and, though himself wounded, continued his work. On another occasion he went across the open under shell fire to attend to the wounded.

Temp. Lieut. William John Knight, M.D., 73rd Fd. Amb., R.A.M.C., for conspicuous gallantry and devotion to duty when in charge of an advanced dressing station under heavy shell fire. He continued to attend the wounded with great coolness.

SIR DOUGLAS HAIG AND THE MEDICAL SERVICES.

THE recently published dispatch of the British Commander on the Western Front contains the following:—

THE MEDICAL SERVICES.

All branches of the Medical Services deserve the highest commendation for the successful work done by them, both at the Front and on the Lines of Communication. The sick rate has been consistently low; there has been no serious epidemic, and enteric fever, the bane of armies in the past, has almost completely disappeared owing to preventive measures energetically carried out. The results of exposure incidental to trench warfare during the winter months were to a very great extent kept in check by careful application of the precautions recommended and taught by regimental medical officers. The wounded have been promptly and efficiently dealt with, and their evacuation to the base has been rapidly accomplished. The close co-operation which has existed between the officers of the Regular Medical Service of the Army and those members of the civil medical profession who have patriotically given their valuable services to the Army has largely contributed to the prevention of disease and to the successful treatment and comfort of the sick and wounded. As part of the Medical Services, the Canadian Army Medical Corps has displayed marked efficiency and devotion to duty.

The valuable nature of the work performed by the officers of the Central Laboratory and the Chemical Advisers with the Armies in investigations into the nature of the gases and other new substances used in hostile attacks, and in devising and perfecting means of protecting our troops against them, is deserving of recognition. The efforts of these officers materially contributed to the failure of the Germans in their attack of December 19th, 1915, as well as in the various gas attacks since made.

MENTIONED IN DESPATCHES.

THE War Office has just issued the dispatches from General Barnardiston on the operations of the Tsingtau Expeditionary Force in September, October, and November, 1914. Among the officers specially mentioned are:—Major J. A. Hartigan, M.B., R.A.M.C., Senior Medical Officer, General Staff; Capt. G. H. Dive, R.A.M.C., attd. 2nd South Wales Borderers.

THE CAMEROON CAMPAIGN.

THE dispatches of the above campaign have just been published. The following officers are mentioned for distinguished and meritorious service by

Sir Charles Dobell:—Major E. B. Booth, D.S.O., Royal Army Medical Corps; Temp. Capt. T. M. R. Leonard, West African Medical Staff; Lieut.-Col. J. C. B. Statham, C.M.G., Royal Army Medical Corps.

The following officers are mentioned for distinguished and meritorious service by General Cunliffe:—West African Frontier Force (Nigeria Regt.). Dr. J. C. M. Bailey, West African Medical Staff; Dr. W. S. Clark, West African Medical Staff; Dr. W. E. S. Digby, West African Medical Staff; Dr. W. H. Peacock, West African Medical Staff; Dr. T. H. Suffern, West African Medical Staff; Dr. C. E. S. Watson, West African Medical Staff; Dr. R. F. Williams, West African Medical Staff.

OBITUARY.

SIR JAMES FREDERIC GOODHART, M.D., LL.D., F.R.C.P., LONDON.

WE regret to record the death of Sir James Frederic Goodhart, which took place at his residence in Portland Place, W., on Sunday, May 28th. He was in his 71st year. Goodhart received his medical training at Guy's Hospital, and after taking the qualification of the English Colleges, graduated M.B., C.M. of Aberdeen University in 1871 proceeding to the M.D. degree two years later. In 1899 his old University conferred on him the honorary LL.D. degree. In 1880 he became F.R.C.P.Lond. He was Pathologist at Guy's Hospital in 1875, and two years later was

His Harveian Lectures on Common Neuroses, which were published in book form, have already been referred to in our columns. With Dr. G. F. Still he wrote "Diseases of Children," a book which, now in its tenth edition, is a standard work. He also contributed the articles on Influenza and Asthma in Allbutt and Rolleston's "System of Medicine." Goodhart became Consulting Physician to Guy's Hospital in 1899, and in 1911 he was created a baronet. Lady Goodhart died in 1915, leaving two sons, the elder Mr. Ernest F. Goodhart, who succeeds to the title, being honorary secretary to Princess Mary's Soldiers' and Sailors' Fund.

DR. JOHN HAROLD, M.B., M.R.C.S., L.R.C.P., LONDON.

DR. JOHN HAROLD died at his residence, 65, Harley Street, London, on May 27th, after a long illness. He was born in Dublin, and was educated at Belvedere College, Dublin, University College, London, and at Charing Cross Hospital, being admitted a member of the Royal College of Surgeons, England, and licentiate of the Royal College of Physicians, London, in 1889, and taking the M.B., B.Ch., and B.A.O. degrees at the Royal University of Ireland, in 1901. Dr. Harold, who had held various positions at Charing Cross Hospital and its medical school, including that of medical registrar at the Hospital, was physician to the St. John and St. Elizabeth Hospital, St. John's Wood, and medical referee to the London Cremation Company. He was senior assistant editor of "Quain's Dictionary of Medicine," for which he wrote many articles, and advisory editor of "The International Clinics."

CHARLES EDWARD FITZGERALD, M.D.DUB.

Hon. Surgeon-Oculist to the King in Ireland; Ex-President of the Royal College of Physicians of Ireland.

IT is with great regret we record the death of Dr. Charles E. FitzGerald, for many years one of the leading ophthalmic surgeons in Dublin, and recently President of the Royal College of Physicians of Ireland. He died on May 27th, after a surgical operation, at the age of 73.

FitzGerald was the only surviving son of the late Baron FitzGerald, a distinguished Irish judge, who resigned his seat on the Bench in 1882, because he regarded the duties imposed upon the judges by the Crimes Act, then passed, as unconstitutional. He was born in Dublin, and educated at Trinity College, where he took his B.A. degree in 1864, and his medical degrees in 1868. He subsequently took the M.D. degree in 1874, and he became a Fellow of the Royal College of Physicians in 1886. After qualification he studied ophthalmology in Paris, and soon after his return to Dublin he was, in 1873, appointed Ophthalmic and Aural Surgeon to the House of Industry Hospitals. He subsequently became Surgeon to the National Eye and Ear Infirmary, but, on its amalgamation with St. Mark's Ophthalmic Hospital to form the Royal Victoria Eye and Ear Hospital, he retired from active hospital work. His withdrawal was due to the difficulty of transferring to the new institution the entire staffs of the two hospitals it replaced. FitzGerald, although the Senior Ophthalmic Surgeon in Dublin, and engaged in active practice, generously gave up his place to younger men. He was for some time Lecturer on Ophthalmic Surgery in the Carmichael School of Medicine, and afterwards Professor of the same subject in the Royal College of Surgeons.

Early in his career FitzGerald gained a large practice, and he remained in busy practice to the week of his death. He wrote little in recent years, and devoted his leisure time to music and art. A man of retiring habits, he never sought publicity, but when the post of President of the Royal College of Physicians was offered to him in 1912, he performed its duties, public and private, with great dignity and efficiency. Of marked individuality, as shown by his face, his dress, and a touch of brogue, he was devoid of any trace of pomposity or affectation. He gained the goodwill of all by his genial comradeship, his kindness

appointed Assistant Physician. He also joined the staff of the Evelina Hospital for Children. Goodhart soon attained to a prominent position in the medical world, and for many years enjoyed a large consulting practice. Although recognised as an authority on diseases of children, his work was by no means specialised, but ranged over a wide field. His pathological work on the liver and spleen is well known, and he also wrote with distinction on respiratory and renal disorders.

and his transparent honesty. He spared no efforts to perform all the duties of President of the College and to make himself conversant with the details of College business, which must often have been, to a man of his tastes and pursuits, in themselves dull and repellent. On the termination of his office he presented to the College a handsome badge of office to be worn by subsequent Presidents.

"Whom the gods love die young." Charles Fitzgerald, though past three score years and ten, was surely loved by the gods, for he was still young. Age had no doubt mellowed him, but he had still the joy and the freshness of youth. His friends, while they miss him and regret his death, had not the unhappiness of seeing him grow old and fail in bodily and mental powers, and they are glad that he was spared the misery of a long or painful illness.

DR. HUGH WHITE, M.B., CH.B., DEVONPORT.

THE death has taken place at Devonport of Dr. Hugh White, a well-known local medical practitioner. The deceased gentleman was a native of Dregghon, Ayrshire. He received his medical training at Glasgow University, graduating M.B., Ch.B., in 1909. After occupying several medical positions, he was appointed surgeon at the Devonport Royal Albert Hospital. Subsequently he commenced private practice at Devonport, and enjoyed a wide popularity.

REVIEWS OF BOOKS.

SURGERY IN WAR. (a)

OF the making of books there is no end. We have already a large number of volumes on subjects connected with the world war, and now the surgical side of the conflict comes under review.

Major Hull's work, "Surgery in War," is a praiseworthy effort, in Sir Alfred Keogh's words, "to take stock, as it were, of the surgical position, to apportion values to various methods of treatment, and to obtain some appreciation of their results." Major Hull has had the advantage of assistance from several brother officers with experience in France. Lieut.-Col. Harrison deals with the bacteriology of wounds, and it must be remembered that the last war experience of the R.A.M.C., viz., in the South African Campaign, was not a suitable training for work in a country of flooded trenches and a soil riddled with pathogenic organisms. Appreciative reference is made to the work of Sir A. E. Wright.

Lieut. W. A. Edwards writes, with accurate knowledge, an excellent description of the methods of localising foreign bodies by X-rays. It is suggested that early operation should be performed in abdominal injuries, and Mayo Robson's excellent results are cited.

The book should be of great value to all surgeons employed in the treatment of wounded.

TWILIGHT SLEEP. (b)

It was a relief when we took up "Twilight Sleep," and found that it was written by a medical man. The superabundance of literature on this subject in the lay periodicals by lay authors, has been sufficient to prejudice it in the eyes of the profession. Scopolamine-morphine anaesthesia has in Dr. Hellman a staunch supporter, although he fully realises its disabilities. Those who have employed the treatment in hospital are more firm supporters than those who have used it only in private practice. The amount of time necessary for its careful administration is well-nigh a definite contra-indication in the practice of the busy accoucheur, though if it were possible to equip private hospitals with nurses specially trained in the subject, the treatment could be used more

generally. If Dr. Hellman had called his work a bibliography of scopolamine-morphine anaesthesia, with a note on its administration, the title would not have been miscalled. The bibliography is excellent; the remarks are valuable and deal with the subject from all points of view.

WHEELER'S HANDBOOK OF MEDICINE. (a)

WHEELER'S Handbook of Medicine needs no introduction, for it has attained much popularity both among students and practitioners, and the appearance of a fifth edition indicates that it is still to the fore. Since the issue of the last edition four years ago, the chief advances in our knowledge of disease have been in connection with cardiac diseases, and in consequence the section dealing with these affections has been considerably enlarged. All the other sections have however, been thoroughly revised and brought up to date, and the paragraphs dealing with treatment have in many instances been amplified with a view both to including newer methods and to describing the older ones with somewhat more detail. We think the author of this edition might with advantage have devoted fuller consideration to some of the therapeutic sections. The original object of the book, namely, the correlation of symptoms with the facts of anatomy and physiology, in a volume which does not by its size preclude the possibility of its being used as a companion in the clinical study of disease, has not been lost sight of, and Dr. Jack has well maintained this aim in his critical revision of the work. We note that the older names have been employed in anatomical references, and we venture to suggest that in future editions it would be well to include also the newer nomenclature if the book is to remain popular with students.

The book is clearly and succinctly written, and will be found a trustworthy guide to diagnosis and treatment. It takes a deservedly high place among the smaller text-books on medicine, and, in addition to assisting students in their revision of work for examination purposes, it should prove of much value to the general practitioner in his daily routine. The printing and binding reflect great credit on the publishers, who should participate in the well-merited success the volume is sure to score in the future as in the past.

MEDICAL NEWS IN BRIEF.

Birmingham Skin Hospital.

IN the thirty-fifth annual report of the Birmingham and Midland Skin Hospital, it is stated that the increase in the number of in-patients was 29, and in the number of out-patients 394, making the total of patients treated 6,788. This increase has necessarily occasioned a great amount of extra work by the honorary surgeons, further intensified by the inability—by reason of the war—to relieve the strain by obtaining the help of qualified clinical assistants. The ordinary income of the past year was £3,435, as compared with £3,227 income of the previous year—an increase of £208, mainly due to the majority of the patients of the working class dwelling in army munitions areas being in receipt of higher wages and so better able to pay for the benefits they receive. On the other hand, the events which have influenced greater income have also brought about greater annual expenditure, by the general rise in price, not only of everyday commodities, but also to a serious extent in surgical and medical requisites of all kinds and scientific apparatus indispensable to the special work of the hospital, a combination of causes occasioning an increase in expenditure over income of £208. The increase in expenditure over that of 1914 is £660.

An appeal is made for donations and subscriptions to the radium fund, which is in urgent need of

(a) "Surgery in War." By A. J. Hull, F.R.C.S., Major R.A.M.C.; with a Preface by Sir Alfred Keogh, K.C.B., M.D. Cr. 8vo, pp. 404; 24 plates, 55 figures. London: J. and A. Churchill, 1916. 10s. 6d. net. By Alfred M. Hellman, M.D. (London: H. K. Lewis and Co. 1915. Pp. 197. 8vo.)

(b) "Amnesia and Analgesia in Parturition (Twilight Sleep).

(a) "Wheeler's Handbook of Medicine." By William R. Jack B.Sc., M.D., F.R.F.P.S., Physician to the Glasgow Royal Infirmary, Lecturer in Clinical Medicine in the University, Glasgow. (Edinburgh E. and S. Livingstone. Fifth Edition. 1916. Price 8s. net.)

replenishment, and it is recorded that the electrical and bacteriological departments have now arrived at a stage when they could together exist as an independent unit, and with extended accommodation, additional radium, and under the title of the "Birmingham and Midland Radium Institute," they might confidently expect a much wider sphere of usefulness than is possible so long as they confine their attention to skin diseases only.

Queen's Hospital for Children.

At the annual meeting, on June 1st, of the Governors of the Queen's Hospital for Children, Bethnal Green, Colonel Lord William Cecil, who presided, in proposing the adoption of the report, referred to the great increase in the work which had taken place last year. The in-patients had numbered 2,029, as against 1,736 in 1914, and there had been 42,225 out-patients with nearly 150,000 attendances. The hospital was doing an important national work in conserving child life, and deserved the support of all who had the future welfare of the country at heart. To carry on the work an income of about £16,000 was required annually, and the Committee had to rely upon the benevolent public for nearly the whole of this sum.

Maternity and Child Welfare.

THE Royal Sanitary Institute are offering a prize of £50 and the medal of the Institute for the best thesis, setting out a complete and practical scheme for maternity and child welfare work, suitable for adoption by local authorities. Ante-natal care and the means of exercising it, child welfare from birth to school age, formation and functions of clinics or other suitable institutions, control in the home, home and institutional instruction and treatment, the utilisation of existing organisations or agencies, and the qualifications and payment of officers and workers are among the points that should be dealt with.

Steel Helmets and Head Wounds.

In the House of Commons on May 29th, Mr. Tennant, replying to Mr. Bryce, who asked whether steel helmets had now been provided for all the troops on the Western front; and, if not, whether instructions would be given that when troops leave the trenches they should leave the helmets for the incoming troops, said:—The supply of steel helmets has very nearly reached the number asked for up to the present, and it is believed that sufficient have been issued for the needs of all the British troops within the zone of shell fire in France. As regards the latter part of the question, I think we may safely leave the issue of any such instructions to the General Officer Commanding-in-Chief, in whom we all have the highest confidence, rather than attempt to dictate to him from this House on matters obviously within his purview. Mr. Bryce also asked to what extent the use of these helmets had diminished the percentage of head wounds, which, about six months ago, were 15 per cent., and Mr. Tennant said:—The percentage of head wounds to total wounds in British hospitals in France from February 18th to April 5th is 12.35 per cent.

Swiss Medical Mission.

THE Swiss Medical Mission now in this country to select wounded German prisoners to be exchanged for our own incapacitated soldiers in Germany were entertained at dinner by the City Swiss Club on June 1st. M. Charles Barbezat, chairman of the club, presided, supported by M. Carlin, the Swiss Minister, and the principal members of the Swiss colony in London.

M. Carlin expressed his keen appreciation of the articles which had appeared in the English Press during the last few days, paying tribute to the humanitarian qualities of his country as evinced in the treatment of the British wounded just arrived in Switzerland. Of all the neutral countries, Switzerland had, he thought, suffered most; surrounded by the belligerents, and without any access to the sea, her position was unique in its difficulties, for *per capita* the external trade of Switzerland was the greatest in

the world. They were doing their best to alleviate the sufferings of the wounded of all the belligerents.

The Chief of the Mission, Lieut.-Colonel Sturzenegger, replying to the toast of the "Mission Médicale Suisse," said he had found the German prisoners, particularly the wounded, treated with the greatest possible consideration. In the good air of Switzerland they would gain from 2 lb. to 6 lb. in weight in a week.

Lieut.-Colonel Bray, the English medical officer accompanying the mission, replying later, bore testimony to the good work performed by it, but, amid great laughter, said it would be quite impossible for the German wounded who left England for Switzerland to increase in weight there or elsewhere, they were so well-fed here.

London Street Watering.

Mr. Hayes Fisher informed Sir S. Collins (R., Kennington), in the House of Commons on May 30th, that the President of the Local Government Board had not, after inquiry, learned that any Metropolitan Borough Council had discontinued street watering. In some cases street watering had been reduced for reasons of economy, and in more cases still owing to the difficulty in getting labour. It was the policy of the Local Government Board that there must be no reductions which would create any serious risk to health.

Oxford University.

THE Judges appointed by the Trustees of the Rolleston Memorial Prize have reported to the Vice-Chancellor that they have awarded the Prize to Edgar Douglas Adrian, M.A., M.B., Fellow of Trinity College, Cambridge, and they are of opinion that the papers submitted by George Matthai, B.A., Emmanuel College, Cambridge, are of a high standard of merit.

Nurses' Insurance Society.

At the fourth annual general meeting of the Nurses' Insurance Society on May 30th Mr. Thomas C. Dewey, who presided, stated that during the twelve months under review sickness and disablement benefit amounting to £16,838 had been distributed among the members, as compared with £17,756 in the previous year.

Smallpox Imported from Belgium.

At a meeting of the Bethnal Green Guardians, on May 23rd, Mr. Eickhoff, as the Board's representative on the Metropolitan Asylums Board, stated that for the two weeks ending Sunday there had been admitted to the fever hospitals from Bethnal Green 14 cases of scarlet fever, 15 of diphtheria, six of whooping cough, and one case of measles—a total of 36 as compared with 26 for the previous fortnight. He had reported a fortnight ago that there was a case of smallpox removed from Earl's Court, and he had now to state that it had been transferred to Joyce Green.

Mr. Davies: Is it a vaccinated case?

Mr. Eickhoff: I don't know. It comes from Belgium.

Care of Child Life.

In support of the Royal Free Hospital's urgent appeal for "The Country's Charge"—the saving of the children—a Mansion House meeting has been held by the kind permission of the Lord Mayor, who presided.

In explaining the object of the meeting Sir Charles Wakefield said the hospital was established in 1828. The sick poor could find immediate shelter and relief without any letter of recommendation. There were now 165 beds, and over 2,000 in-patients and 40,000 out-patients were annually benefited. An urgent appeal was now being made for £200,000 to enable the hospital to extend further its work for the children of the nation, and to take steps to prevent the present lamentable waste of infant life. It was the duty of the country to do all in its power to preserve infant life. It was estimated that, if it had been possible forty years ago to provide the measures by which numbers of mothers and babies had benefited

at the Royal Free Hospital, we should now have over a million more men to safeguard our country. Their Majesties the Queen and Queen Alexandra had graciously accepted a reproduction of the picture which had been adopted as the badge of the hospital's appeal.

Dr. Jane Walker said a generous donor had given a piece of land valued at £30,000 adjacent to the hospital in the Gray's Inn Road, upwards of an acre in extent. One of the departments it was proposed to erect on this land was one for the treatment of tuberculosis.

It was stated that £5,000 had been received to date in response to the appeal.

Derby's Mental Hospital.

WITH 85 additional patients received from institutions now occupied by wounded soldiers and the staff reduced by ten since a year ago, the committee of the Derby Mental Hospital appealed to the local Military Tribunal on May 24th for the exemption of four employees. These were a farm labourer, a farm carter, a joiner and an assistant engineer, all married, but not included in the exemption arrangements made by the Board of Control.

The medical superintendent (Dr. S. R. Macphail) stated that 60 per cent. of the eligible staff enlisted at the outbreak of the war, and altogether 40 per cent. of the whole staff had joined the forces. The four in question were the only men of military age left, and they acted as attendants and could not be dispensed with. In fact, in his opinion, the limit of reduction consistent with public safety had been passed. The only way to decrease the number of patients was to allow them to escape. (Laughter.) There were few escapes in normal times, but during the past month three patients had got away, one being still at large.

Conditional exemption was granted in respect of all four of the men.

Radium and Plant Life: Result of Mr. Sutton's Experiments.

THE experiments with radio-active ores and residues as stimulants to plant growth carried out on his firm's trial grounds at Reading by Mr. Martin H. F. Sutton, did not, according to his report of the second series of experiments just published, confirm the expectations formed in some quarters, but they were none the less instructive and definite.

Mr. Sutton had been led to believe, as others had been, that the residues and ores of radium mines in Cornwall had proved beneficial to plant life, and undertook a series of practical investigations. His experiments were admirably designed to test whatever merits the various commodities might possess. The result is disappointing.

No evidence whatever of beneficial influence of the ores or residues was perceptible in any of the various farm and garden crops used in the experiments. It may be that a better understanding of the precious mineral and the uses to which it can be applied will necessitate a revision of the Reading results; but so far as the present state of knowledge goes Mr. Sutton's conclusions are to the effect that plant life is not consistently or appreciably affected one way or the other by the influence of the radio-active ores and residues operating directly or indirectly upon the plants.

MEDICAL WAR ITEMS.

NEWS has been received of the death in action of Lieut.-Colonel George Oliver Moorhead, eldest son of the late Brigade-Surgeon G. A. Moorhead. Born in Mauritius and educated at Malines, Belgium, and Edinburgh University, he was practising as a doctor in the Transvaal. When the last South African War broke out he was commandeered by the Boers, and placed in charge of a field ambulance. Seizing an opportunity of escaping he joined the British forces, and was given charge of a hospital. He was at Colenso, and took part in other actions, receiving the Queen's and King's medals with clasps. When

the present hostilities commenced he abandoned the medical profession for military work, joining the Union Defence Force. Lieut.-Colonel Moorhead, who was formerly in command of the Northern Mounted Rifles, assisted in quelling the South African rebellion and went through the German West African campaign, at the close of which he volunteered for further service. He was 50 years of age. The death of his brother, Brevet Colonel A. H. Moorhead, A.D.M.S., was recorded only two months ago.

Captain GAVIN ALEXANDER ELMSLIE ARGO, M.B., Royal Army Medical Corps, who has been wounded, lived at the Manse, Kincardine-O'Neil, Aberdeenshire, and was educated at Aberdeen University, where he took his medical degree. He has been a captain in the Royal Army Medical Corps since last August.

Lieutenant HARRY JOHN SULLINGS KIMBELL, Royal Army Medical Corps, who died on May 28, was until recently in charge of Preston Hall Hospital, Maidstone. He received his commission as temporary lieutenant in August of last year. Lieutenant Kimbell had his medical education at St. Bartholomew's Hospital, and he was an M.R.C.S. England, and an L.R.C.P. London, 1907.

Mrs. HELEN FARNWORTH, of Wolverhampton, left £1,200 among three Wolverhampton hospitals.

Captain REGINALD TAVERNER JOHNSON, of Darlaston, left £1,000 to the North Staffordshire Infirmary.

Miss ANNIE EMILY PITMAN, of Tunbridge Wells, left £1,000 to the Tunbridge Wells General Hospital.

Mrs. ANNA CATHERINE BASTARD, of Bracknell, Berks, left £200 to the Taunton and Somerset Hospital.

Mr. MAURICE LINDSEY O'CONNOR MORRIS, of Gortnamona, Tullamore, King's County, left £2,500 to his nurse, Linda Kearns, if in his service at his death.

Sir THOMAS BOOR CROSBY, M.D., F.R.C.S, the first medical man to become Lord Mayor of London, occupying that office 1911-12, left £38,905.

A MOVEMENT is on foot to complete a memorial to the late Dr. Fletcher Little, medical officer of health for Harrow. It will take the form of apparatus for the instruction of blinded soldiers in massage.

Mrs. JOSEPHINE RAPHAEL, of Porchester-terrace, W., and Villa Raphael, Cannes, left £100 to the London Homeopathic Hospital, and £300 each to the London Hospital and the Royal Hospital for Incurables at Putney.

THE Metropolitan Convalescent Institution has received £300 from Smith's (Kensington Estate) Charity, £300 from the executors of the late Mrs. Gore Lloyd, and £50 from the Worshipful Company of Grocers.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

LETTERS TO THE EDITOR and Original Papers intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of *bona fides*. These should be addressed to the Editor at the Offices of this Journal; if in Ireland, to the Dublin Office, 29 Nassau Street; from all other parts of the United Kingdom these should be addressed to the London Office, 8 Henrietta Street, Strand.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

AN IRON TONIC!

At a concert to wounded soldiers at the Kitchener Hospital, Brighton, a young soldier from the Overseas Forces, who had been rendered dumb from shell shock in France, recovered his speech when listening to the humorous song "Any Old Iron." He became excited, and shouted out "Old iron!"

TENAX (Walsall).—You will see he has obtained recognition by reference to the list of birthday honours we publish in this issue.

LUMBAR (Bow, E.).—The condition is probably secondary to the lordosis.

NERVES

At the Thames Police Court a young man asked Mr. Cancellor to sign a "green" form to enable him to leave the country. He was not in good health, he said.

Mr. Cancellor: From what are you suffering?

Applicant: Nerves.

Mr. Cancellor: Have you a medical certificate?

Applicant: No.

Mr. Cancellor: I shan't sign it.

REFEREE (London, S.W.).—We agree with you regarding the unsatisfactory nature of the procedure, and hope to refer to the subject in detail at an early period.

Dr. J. M.—We have written you.

J. DAVIES (Battersea) will receive a private communication after necessary inquiries have been made.

DAYLIGHT SAVING.

At a meeting of the City of London Guardians on May 30th, it was stated that, as a result of the Summer Time Act, 10,000 ft. of gas and 66 units of electricity were saved at the City of London Military Hospital, Homerton, in the first week.

X. L. (Cheltenham).—There are at least four preparations of British manufacture which are being advertised as substitutes.

PERCUSSION (Birmingham).—A solution of two to four grains to the ounce should give satisfactory results.

SOLO (Brighton).—The condition is one of recurrent melan- cholia.

Meetings of the Societies, Lectures, &c.

THURSDAY, JUNE 8TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNECOLOGY) (1 Wimpole Street, W.).—8 p.m.: Specimens—Dr. J. D. Malcolm: Strangulation of Fibromyomatous Uterus caused by Torsion of the Corpus Uteri on the Cervix. Dr. F. J. McCann: (1) Case of Pregnancy in a Large Fibromyomatous Uterus; (2) Soft Fibroma of the Paravaginal Connective Tissue. Short Communications—Dr. H. Russell Andrews: (1) Three Cases of Hematoma of Abdominal Wall; (2) Case of Primary Abdominal Pregnancy. Paper—Dr. John Phillips: Acute Hepatic Toxæmia complicating Pregnancy and Labour.

BRITISH OTO-LARYNGOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square, W.).—5 p.m.: Meeting.

Vacancies.

Dublin, Temple Street.—Assistant Surgeon. Applications to the Hon. Secretary of Medical Board. (See advt.)

University of Dublin.—Chair of Surgery. Applications to the Registrar of the School of Physic. (See advt.)

Darlington Hospital and Dispensary.—House Surgeon. Salary £160 per annum, with board, residence, laundry, etc. Applications to H. F. Creek, Secretary, 46 Greenbank Road, Darlington.

Royal Berkshire Hospital.—House Physician. Salary £250 per annum, with apartments, board, and washing. Applications to Herman Burney, Secretary, Reading.

Sheffield City Hospital: Infectious Diseases.—Medical Officer. Salary £225 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Lodge Moor Hospital.

Royal Victoria and West Hants Hospital, Bournemouth.—House Surgeon. Salary £150 per annum and extras, with board,

lodging, and washing. Applications to Gordon M. Saul, Secretary.

Hampstead General Hospital, Haverstock Hill, N.W.—Resident House Physician. Salary £200 per annum, with usual allowances. Applications to the Secretary.

East Sussex Hospital, Hastings.—House Surgeon. Salary £150 per annum, with board and washing. Applications to the Secretary.

Royal Devon and Exeter Hospital.—House Physician. Salary £150 per annum, with board, apartments, and washing. Applications to Samuel S. Cole, Secretary, Exeter.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Lady House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38, Barton Arcade, Manchester.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with board, rooms, attendance and washing. Applications to the Secretary.

The Sheffield Royal Infirmary.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.

North Ormesby Hospital, Middlesbrough.—Assistant House Surgeon. Salary £150 per annum, with board, residence, and washing. Applications to A. Stanley Brunt, Secretary.

Appointments.

ESTERMAN, T., M.B., Ch.B.St.And., House Surgeon at Leicester Royal Infirmary.

HEDDEN, R., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for the Honiton District of the county of Devon.

HOLLAND, EARDLEY, M.D.Lond., F.R.C.S.Eng., Assistant Obstetric Physician to the London Hospital.

Births.

BARKLEY.—On May 14th, at Athbeagh, Sandy Lane, Cheam, Surrey, the wife of Lieut.-Col. J. Barkley, 3rd H.C.F. Amb., R.A.M.C., of a daughter.

BROCKMAN.—On May 31st, at Ellerdale, Ashcroft, Cirencester, Glos., the wife of John Thomson Brockman, of a daughter.

CORRY.—On April 5th, at The Oaks, Liss, Hants, the wife of H. B. Corry, B.A., M.R.C.S., L.R.C.P.Lond., of a daughter.

HAIG.—On May 30th, at Hedgeley, Banister Road, Southampton, the wife of Lieut.-Col. P. B. Haig, I.M.S., of a daughter.

MOBERLY.—On May 29th, at Avondale, Ditton Hill, Surrey, the wife (née Violet E. Stevenson) of Dr. Alan V. Moberly, of a daughter.

MORTIMER WOLF.—On Monday, June 5th, at 81 Wimpole Street, W., the wife of Captain A. E. Mortimer Wolf, F.R.C.S., R.A.M.C., of a daughter.

O'CONNOR.—On May 29th, at 21, Alexandra Mansions, Chelsea, to Capt. F. W. O'Connor, R.A.M.C. (temporary), and Zella O'Connor, a daughter.

SHONE.—On May 26th, at 40, Bath Street, Jersey, the wife of Henry J. Shone, M.B., B.C.Cantab., of a son.

WALKER.—On May 30th, at Malton, the wife of Dr. L. C. Walker, The Mount, of a daughter.

WAKEFORD.—On May 31st, at 728, Fulham Road, the wife of V.D.C. Wakeford, M.B., B.S., of a son.

Marriages.

LANG-HODGE—SYMES.—On May 30th, at Crediton Church, Captain W. Lang-Hodge, R.A.M.C., to Marian Hilda Symes, Manor House, Crediton.

PHILLIPS—STEWART.—On June 2nd, at St. Ninian's Episcopal Church, Glasgow, Captain Richard Biddulph Phillips, R.A.M.C., elder son of Mr. and Mrs. Jacob Phillips, of Ellerker Lodge, Richmond, Surrey, to Katherine Jane, youngest daughter of the late Captain James Stewart, 16th Lancers, and Mrs. Stewart, of Williamwood, Cathcart, Renfrewshire.

SANER—DENOUX.—On May 31st, at Brompton Oratory, S.W., by the Rev. Father John Talbot, John Godfrey Saner, M.C.Cantab., F.R.C.S.Eng., of Guy's Hospital, son of the late Captain C. T. Saner, of Natal, S. Africa, to Fernande Gabrielle, daughter of the late Monsieur Denoux and of Madame Denoux, 44 Rue Nicole, Paris.

SHARMAN—CHISHOLM.—On June 3rd, at St. Clement's Church, Hastings, Henry Sharman, M.D., eldest son of the late Francis Sharman, of Hampstead, to Nancy Matheson, younger daughter of the late William Chisholm, of Hampstead, and of Mrs. Chisholm, of High Wickham, Hastings.

WYATT—BRIGGS.—On May 31st, at St. James's, Piccadilly, H. D. Wyatt, M.D., of Green Lanes, Godalming, to Gertrude May Briggs, widow of Charles Briggs, of Norwood.

Deaths.

CENTER.—On Friday, April 28th, at the Royal Naval Hospital, Bighi, Malta, of wounds received on April 27th when H.M.S. Russell was sunk in the Mediterranean, William Rudolf Center, M.B., Fleet Surgeon, Royal Navy.

ELLIMAN.—On June 3rd, at Bella Vista, San Remo, Italy, after a very long illness, Arthur Charles Elliman, M.R.C.S., L.R.C.P., aged 50.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, JUNE 14, 1916.

No. 24.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

News and Nerves.

It is obviously useless to add to the chorus of disapproval which on general and sufficient grounds has been sounded in the lay press on the subject of the manner of the Admiralty's first announcement of the great battle in the North Sea. There is, nevertheless, a medical side to the question to which, in view of future announcements of a similar nature, it is fitting that attention should be directed. The battle took place on Wednesday, May 31st, and the public was informed so late on Friday, June 2nd, that it was impossible for anyone to obtain further details. Whether this was done of malice prepense, so as to save the officials from being subjected to inquiries to which no answers were possible, I do not pretend to know; but this I do know, that the manœuvre, if it can properly be so described, was the cause of a very great deal of insomnia on Friday night. It is not fair that people whose nerves are already on the stretch should be subjected to the ordeal of partial information depressingly presented, just before bedtime. To have waited until the morning could have done no one any harm. Bad news is more bearable in daylight.

So far as has been ascertained up to the time of writing, the toll of **Medical Officers and the Battle.** medical men exacted by the great battle amounts to about 25, to which must be added at least three who went with Lord Kitchener to his untimely and much lamented end. Among these, no less than nine appear to have been probationers—students, that is, in the final years of their studies. To the relatives and friends of these surgeons and probationers we tender our respectful and most heartfelt sympathy. Steadfastness and devotion to duty are never wanting in medical men in times of stress, but there is a something about the conditions of service at sea which calls for these qualities in a very exceptional measure, to which Britons are always anxious to render homage whenever they are displayed.

Christopher Addison.

The Birthday Honours list, which is a long one, reveals its usual economy of recognition of medical service to the State. Of the names of those members of the profession who have been honoured on this occasion the best

known to the public is certainly Dr. Christopher Addison, to whom we offer our heartiest congratulation on his Privy Councillorship, a distinction which is much coveted in the political circles in which he now moves. Christopher Addison was born in Yorkshire in 1869. After qualifying in 1891, he proceeded to the M.B., B.S.Lond. in 1892, the M.D. in 1893, and the F.R.C.S.Eng. in 1895. He was for some time Lecturer on Anatomy at Charing Cross Hospital, and Dean of the School, also Professor of Anatomy at University College, Sheffield. When he was returned as M.P. for Hoxton in 1910, he was Lecturer on Anatomy at his old school, Bart's, at which he was a popular and respected teacher. He speedily made a mark in political life; but he found his new activities so exacting that he relinquished his professional and scientific work to become an administrator. He is a staunch upholder of professional interests in the House of Commons, and the profession may well feel honoured by the distinction which has been conferred upon him.

Dr. ARMAND RUFFER, on whom a **Sir Armand Ruffer.** knighthood has been conferred, thoroughly deserves his distinction.

Some years ago he contracted a *post-mortem* wound which laid him up for a long period of time, and he recovered from it so partially that it became evident that he would not be able to remain in this country. He therefore went to Egypt at Lord Cromer's suggestion, where he has since done remarkably good work, in spite of the physical disabilities which his illness continued to impose upon him. In 1905 he was made a C.M.G.; he is President of the Sanitary, Maritime and Quarantine Council of Egypt, and Egyptian representative on the International Bureau of Hygiene in Paris. He was one of the founders of the British Institute of Preventive Medicine. He has already received a great number of foreign decorations. Armand Ruffer took his B.A. of Oxford in 1883, his M.B. in the same University in 1887, and his M.D. in 1889. He has contributed a great deal to our knowledge of bacteriology, and is, in the widest sense, a sanitarian. Sir Armand Ruffer is brother to Mr. Ernest Ruffer, who was for many years President of the French Hospital in London. They are sons of Baron Alphonse de Ruffer, a native of Lyons.

PROFESSOR NESTOR TIRARD, who, as **Sir Nestor Tirard and Others.** his name implies, is also of French extraction, and who now adds another title to the staff of King's College Hospital, has been Professor of Medicine at King's College for many years. He became an M.B. London in 1877, and an M.D. in 1881. Besides being physician to King's College Hospital, he was for some time physician, and is now consulting physician, to the Evelina Hospital for Children. He has written much on the subject of renal diseases, on which he is an acknowledged authority: in addition there is the well-known text book on "Medical Treatment" to the credit of his pen. He is now Lieut.-Colonel commanding the 4th London General Hospital. The other titled members of "King's" staff are Sir David Ferrier and Sir Hugh Beevor, Bt., consulting physicians; Sir Watson Cheyne, Bt., senior surgeon; Sir St. Clair Thomson, laryngologist; and the immortal Sir Ronald Ross, who is the physician for tropical diseases.

OUR dental colleagues will be gratified with the distinction which has been conferred upon Mr. Francis Mark Farmer. Mr. Farmer is already the recipient of a presentation from the Secretary of State for War, 1902. He has been one of those who have successfully sought to raise dentistry from a mere art into a science which includes the osteology of the jaws as well as bacteriology of the gums, and has approached the practice of his profession from a thoroughly scientific as well as from a practical standpoint. He was qualified in 1894.

THE article on the "Treatment of War Psychoses" which appeared on page 507 of our last issue gains additional point from recent events.

To every medical man who read the evidence at the court martial on the execution of Mr. Skeffington, it was quite obvious that this most deplorable event could not have occurred if the responsible officer had been in perfectly good health. Now there are an enormous number of military men, officers and men, who, though not seriously ill, are by no means well; who are "déséquilibrés" as the French say, and who ought in consequence to be under expert treatment. Such treatment is admittedly not easy to obtain, but a little organisation of such talent as is available would very soon make all the difference between really good results and the present chaotic state of matters, in which, with the label of neurasthenia affixed to him, the unfortunate sufferer is either returned to duty for which he is totally unfit, or drifts his wretched way into an institution for the insane.

An instance of the former is provided by the court martial above referred to. The following is an extract from the speech of the counsel for the defence, as given in the *Times*. "The Court could appreciate what occurred at the battle of Mons and how it affected Captain Colthurst. General Bird's evidence was

that Captain Colthurst completely broke down after that battle, and that his conduct was such that he had to be suspended from duty. In view of this they could imagine his mental condition in such circumstances as those of April 26th. The wounds he received at the battle of the Aisne had a serious effect on his system. Physically he was a wreck, and mentally he had suffered in a corresponding degree." If this is not a gross exaggeration, it is quite obvious that this officer should not have been placed in a position where, by any possible combination of circumstances, he could be called upon to exercise judgment on any military question, however trivial. He ought to have been under suitable suggestional treatment in a hospital provided for such cases.

AN example of the other extreme is provided in a letter which appeared in the *Military Mail* on June 2nd. It is signed "E. H. Kelly," who writes from the National Relief

Fund Sub-committee, Portsmouth, "I have found one class of men who do not appear to be receiving adequate attention or treatment: those who are suffering from acute nervous shock, causing in certain cases a complete mental breakdown, which may be of a temporary or permanent nature. Those men require more supervision than can be arranged conveniently in naval or military hospitals, and consequently they are frequently discharged to their homes with so-called 'neurasthenia,' which may be considered 'attributable' or 'non-attributable.' In certain instances bad cases have been sent home without even an attendant for the journey, with disastrous consequences. Later, more acute symptoms may appear, and their relatives have no choice but to apply to the relieving officer for their admission to the local asylum, where they are treated as pauper lunatics. In spite of the fact that the full cost of their maintenance may be deducted from their pensions, they are still technically paupers." The letter closes with the suggestion that an extension of Lord Knutsford's scheme for the treatment of nerve-cases might meet the situation. It is at any rate abundantly clear that something ought to be done and done speedily.

A CORRESPONDENT writes to ask me whether it is possible that the body of a child who died from measles is capable of conveying the virus of that disease, to which I must reply that I do not know. This is a question which arose at Middlesbrough not very long ago, when the Stipendiary Magistrate was called upon to come to a decision on the subject. There appear to have been two hearings of the case. At the first hearing, on the ground that there was no actual contact, the case was dismissed. It was then taken to a higher Court, who returned it with the recommendation that the Stipendiary should convict if he was convinced that there was such close proximity as to give rise to infection. Dr. Dingle, medical officer of health for Middlesbrough, said that anyone entering a room where there was the body of a person who had died

from measles was running a grave risk of infection, and Dr. Sidney Mostyn, the medical officer of health for Darlington, said that, judging from analogy in regard to other infectious diseases, risk of infection from a body of a person who had died from measles was considerable. These two medical officers were obviously right in the views which they expressed. Until we know the exact nature of the infection in measles, it is impossible to be dogmatic, but it is quite evident that if error there is to be, it should be on the side of safety.

Mending the B.M.A. THE suggestion made by Dr. Ross, of Bedford, in the letter we published last week, namely, that I should rejoin the British Medical Association and assist in the mend-

ing of it, does not at all appeal to me. While gratefully acknowledging the implied compliment, I fear I must decline to undertake a task which I believe to be outside the compass of any mortal man, or indeed of any body of immortals. To mend the B.M.A. for political purposes it would be necessary to alter its constitution, which would be a formidable undertaking. Then it would be necessary to overcome the deeply rooted antagonism which the Association has created for itself among the members of the profession; and, finally, it would be necessary to persuade the public generally and the politician in particular, that the purged and purified body which emerged Phoenix-like from its cleansing fires, was no longer governed by noodles and nonentities vested with a little brief authority in virtue of which they masqueraded as diplomats and men of business. I adhere to my view that the B.M.A. is Humpty Dumpty, and I do not flatter myself that I could succeed where all the King's horses and all the King's men have proverbially and notoriously failed.

Its Impotence. Now, I shall certainly be asked why I think that its constitution would have to be changed; so to save trouble I may as well at once proceed to explain. I said recently

that the B.M.A. was "neither fish, flesh, fowl, nor good red herring." In adopting that classical phrase I was not merely swearing at large. I meant to remind my readers of the fact that among the many things that the Association has stupidly arrogated to itself, is the status of a Trade Union. Now, if it was to accomplish anything *vis-à-vis* such an astute politician as Mr. Lloyd George, it was obvious that in the last resort it might have to appeal to the immunities of Trade Union Law. It negotiated about the Insurance Act as though it could so appeal. Mr. Lloyd George knew that this was mere bluff, and he treated the B.M.A. as, in the circumstances, it richly deserved to be treated. But it was the Profession that suffered. If there were to be any hope of effectively mending the B.M.A. for political purposes, the Association would have to become a Trade Union.

Tapers and Tadpoles. I DON'T suppose its existing constitution would permit of this. In any case the present Tapers and Tadpoles (it is the fashion to quote Disraeli) who control the machine would never consent to anything either so definite or so efficient. Their god is respectability. While posing as the leaders of a learned profession, they dally clumsily with the tools of the determined artisan. Willing to wound, and yet afraid to strike, they assume threatening attitudes, exact solemn pledges, and then basely abandon the position. Such appears in their view to be the way in which gentlemen behave. A body which is in earnest, which knows what it wants and means to achieve it, will have to divest itself of this garment of bourgeois pseudo-gentility. It is very well that a suit of broad-cloth should conceal the fustian for Sunday wear, but when the broad-cloth conceals nothing more servicable than motley, it is no wonder that its wearer refrains from taking off his coat. The British Medical Association has never taken off its coat. And it never will; for it dare not. It clings to the respectable exterior, for the good reason that beneath it there is nothing save the multi-coloured motley of the mildly-mannered, middle-headed, middle-class fool.

A Trade. If the Profession really means business in the approaching struggle it must look facts in the face. It may be good policy to assume the airs of a *grand seigneur*, to take your stand upon the basis of a great and learned profession which despises trade, so long as such an attitude is likely to serve your purpose. But when your opponent is vulgar enough to treat you as a trade, to speak of you as a trade, and to approach negotiations with you as though you were a trade, and that a mercenary, commonplace and incompetent one, the sooner you appoint yourself a trade, arm yourself as a trade, and defend yourself as a trade, the better for your own material interests and those of the public whom you serve. The policy of turning the other cheek may appeal to the conscientious objector, but the full virtue of such an attitude is not apparent in the practical politics of a sordid, stiff-necked, and still partially prussianised generation. To the actualities of the British Medical Association I frankly prefer the potentialities of the Panel Medico-Political Union, which seems to have no illusions as to the best methods to adopt towards politicians. It is a real trade union, and makes no fetish of professional gentility.

SINAPIS

ST. PANCRAS BOARD OF GUARDIANS have appointed Mrs. Thackray, a qualified doctor, to act as assistant to her husband, the Medical Officer to the Board, during the present shortage of doctors.

MR. JOHN WILLIAM WILSON, of Harrogate, bequeathed £1,000 to the Leeds General Infirmary, £500 each to the Leeds Hospital for Women and Children, the Royal Bath Hospital and Rawson Convalescent Home, Harrogate, and the Harrogate Infirmary.

CURRENT TOPICS.

The Cause of Carcinoma.

THE cause of carcinoma is one of the most baffling of the problems which have for years past been occupying the minds of men of science. The condition has been known to develop under the influence of a great variety of stimulants, and all researches hitherto have failed to reveal any specific external agent. The only factor common to all these stimulants is the production of a chronic irritation. An interesting article by Dr. A. E. Rockey, published in a recent number of *Surgery, Gynecology, and Obstetrics* (February, 1916), contains a brief and lucid statement of our present position with regard to this subject, and propounds the theory that there is no specific external agent responsible for the growth of a carcinoma, but that the tumour is the result in every case of a defensive tissue growth reacting to a repeated irritation where the latter is sufficiently severe to destroy the limiting basement membrane. That is to say, the irritation provokes the epithelial cells to great karyokinetic activity, and just so soon as the basement membrane is injured will some of these rapidly produced cells find themselves astray amongst the connective tissue cells of the interior. Because of their rapid multiplication they are now atypical epithelial cells becoming more and more embryonal in type and therefore nearer to the surrounding cells of mesoblastic origin. The defensive nature of the reaction causes a diminution of the antagonism between mesoblastic and epithelial cells, whereby the latter having their energy unimpaired continue to multiply rapidly until they not only crowd out the normal tissues so as perhaps to cause pressure necrosis, but also extend by multiplication along the lymph channels and form metastases in the nearest glands. In support of this theory, Dr. Rockey quotes the great variety of stimulants known to have produced carcinoma, mechanical, chemical, thermal and radiant—what other common factor may we hope to find?

Finger Nail Deposits.

THE medico-legal expert has long since learnt to concern himself with details and to consider microscopic evidence of as much importance as any which is plainly visible to the eye. It is a commonplace to deduce from one hair the nationality and temperament of its owner, whereas the study of finger marks and footprints has been reduced to a fine art and yields astonishing results. In a recent number of the *Journal of the American Medical Association* (May 20th, 1916) Dr. Albert Schneider advocates the routine examination of an even more intimate material, always procurable, and always testifying to the habits and recent occupations of the owner—the scrapings from beneath the finger nails. Ordinary cleanliness of personal habits does not remove these nail deposits, they are absent only when the nails are kept trimmed so close as almost to cause bleeding—a rare circumstance. Most commonly these deposits contain bacteria of the streptococcus, staphylococcus and *B. coli* groups, while less frequently yeast cells are found, spores and filaments of the higher fungi, larvae of vermes, etc. Besides these organisms the deposits will contain vegetable or mineral substances according to the occupation of the host. In medico-legal work the examination of these nail deposits will be principally useful in cases of alleged physical violence, and particularly where the victim is unarmed. His nail deposits then will show frag-

ments of skin epithelium, blood corpuscles, and perhaps hair. Dr. Schneider also draws attention to the transmission of infections by means of finger nail deposits. Auto-infection frequently causes boils, carbuncles, and even septicæmia, while he asserts that hetero-infections may be caused by stroking or caressing the head or face, or even by the simple handshake. The wisdom of the Chinese is proverbial, they avoid this danger by shaking hands with themselves. We wonder how soon our lives will be ordered according to our knowledge. The act of kissing is, we know, dangerous in the extreme, and not to be indulged in by any man of science who values his life and health, but let that not affect us unduly, for very soon the physician or surgeon will be the only man permitted to touch another with his hand—after evulsion of the finger nails.

Royal College of Surgeons of Ireland.

THE annual election of President, Vice-President, and Council of the Royal College of Surgeons of Ireland took place on June 9. Mr. William Taylor, Vice-President, was unanimously elected President, and Mr. J. B. Story was elected Vice-President. Sir Charles Cameron was re-elected Honorary Secretary, and the following were elected to seats on the Council:—Mr. W. Stoker, Sir C. Cameron, Sir Lambert H. Ormsby, Messrs. R. D. Purefoy, H. G. Sherlock, Sir Thos. Myles, D. Edgar Flinn, Sir Arthur Chance, S. M'C. Boyd, Sir Robert H. Woods, R. B. M'Causland, T. E. Gordon, E. H. Taylor, F. Conway Dwyer, A. J. M'A. Blayney, R. C. B. Maunsell, T. N. Smith, W. I. Wheeler, and Sir C. Arthur Ball. The only new members of Council are Colonel Edgar Flinn and Sir Arthur Ball. They take the places vacated by Mr. R. Lane Joynt, who was a candidate for the Vice-Presidency, and by the death of the late Sir Charles Ball.

A Prize Child.

COLE NEWTON, of New Jersey, has put forward a comprehensive scheme for improving the physique and physiology of American children, comprising systematic physical examination throughout their academic curriculum, with allocation of marks for qualities ranging from personal beauty to dental integrity. What is more important, unless certain minimums are satisfied, progress to a higher grade is not to be welcomed, the inference being assumed that unless bodily efficiency is assured, that advance in studies constitutes a strain upon the child's economy, even although mentally, at a superficial consideration, they are capable of meeting the promotion. The procedure culminates upon leaving the primary school, when those pupils who have attained a certain marking for physical condition are allowed to compete for substantial money prizes. Whilst fully sympathising with regular inspection of children's health, we consider the introduction of any competitive element as grossly unfair. If a boy or girl possesses a comely face or a symmetrical little body, it no particular credit to his or her efforts—though it may be a credit to the parents. Because Master Smith can swell his chest bigger by two inches than Master Brown, is no reason to present him with 500 dollars and a swelled head. Children, being for the most part natural animals, are instinctively vain of their physical good qualities; aggravation of such vanity is to be discouraged. Supervise the health, mental and physical, of our children, vigilantly and constantly. Do not make the pain experienced by the plain or physically defective child more exquisitely acute than it can be already

by decorating his more happily endowed brothers and sisters after the manner of prize cattle.

Silence.

ATTENTION has recently been drawn to the necessity of forethought in the selection of a hospital site. Too frequently, retirement, relatively pure air, and tranquillity are entirely sacrificed to a central position. Such a position is indeed imperative from a city point of view, in order that urgent cases may come under treatment without delay. The oxygen question, therefore, must perforce take second place; but much more might be done to ensure an absence of gross and disturbing sounds in the immediate vicinity of hospitals. Placed upon some central artery of traffic, in the midst of what in certain cities amounts to a continuous roar of vehicular business, such conditions are far from hastening the recovery, or conducing to the rest of patients, high strung with pain and exhausted from insomnia. Young America, with characteristic thoroughness, has devised what are termed "zones of silence" in connection with such institutions, whereby a compulsory diversion of heavy traffic is enforced for a certain radius around the building. In home cities we are satisfied with the laying of wood pavement over a street area corresponding to the hospital frontage. The futility of such a characteristic compromise is self-evident.

State Medical Service.

As if to emphasise the truth of the warnings of "Sinapis" on the above subject, the medical correspondent of the *Times* returns to it in the issue of our contemporary of June 12. He states that "There is reason to think that the relations of the medical profession to the State and public must soon undergo a change. As the demands of the Army become more insistent, the dearth of doctors becomes more evident. The result has been a very ill-informed attempt to show that the Army is getting more than its share. This statement is both mischievous and untrue. The Army needs all the doctors it has got.

"The real waste of doctors is going on in civil life—a fact not usually noticed by the carping critics of the best medical service organisation in the world. The waste results from lack of organisation and allows several doctors to compete still for the work in small areas while larger areas are undermanned. In other words, the civilian medical profession is where it was before the war.

"This is a great national question, and there is every reason why the Government should take it up forthwith and settle it. The settlement must be upon broad lines and must be national; yet it must regard interests already established. At present one type of doctor is charging £9 gs. with all expenses for "doing a locum," while another type is relinquishing a good practice—losing it often—for the sake of his country. I know of several cases in which practices have been lost beyond recall because their owners joined the Army. All this worry and waste arises out of the lack of a national scheme, and if the time for laying the foundations of a State medical service was ever ripe it is ripe now."

It is widely believed that there is now a close political relationship between Lord Northcliffe and Mr. Lloyd George, and the latter appears at present to be the spoilt darling of the Harnsworth Press. We have more than a shrewd suspicion that the quotation from the *Times* does not state the view alone of one individual. The voice may be that of the *Times* Medical Correspondent, but, if we mistake not, the hand is that of the politician.

The lesson for the medical profession is clear. We must act on the assumption that State medical service is coming. We must organise, so that a united profession can meet the politicians on their own ground and exact fair treatment. After the Insurance Act debacle, it is certainly not to the British Medical Association we must turn for light and leading.

Soldiers Disabled by Disease.

WE receive an Army Order issued on June 11th under Royal Warrant, relating to pensions for soldiers discharged on account of disease not wholly due to war service, but aggravated by it. Amongst other enactments it provides that a European soldier discharged in consequence of the present war as unfit for further service on account of disease not directly and wholly due to war service, but aggravated by it, may be granted a pension equal to four-fifths of the pension, including allowances for children, which would have been awarded to him under Articles 1 to 3 of the Royal Warrant of May 21st, 1915, if his disability had been due directly and wholly to war service. We consider this but elementary justice. The State already, by means of the Workmen's Compensation Act, holds an employer responsible for any disease which, though present before an accident, has been so aggravated by such accident as to incapacitate the workman totally or partially. To treat the soldier broken in our war worse than the man in the workshop is repugnant to all good feeling.

Many sad cases are known where latent disease, which, but for the rigours of campaigning, might never have disclosed itself, has resulted in total breakdown in health. Such are as truly war wounded as if mangled by shell, and should receive every consideration from a grateful country.

PERSONAL.

SIR ARTHUR CHANCE, F.R.C.S.I., has been appointed Consulting Surgeon to Dr. Steeven's Hospital, Dublin.

DR. A. E. BARNES, Honorary Physician to the Sheffield Royal Infirmary, has left for an important overseas military centre, where he will take full medical control of hospital work in connection with His Majesty's Forces.

LIEUTENANT-COLONEL ARTHUR L. A. WEBB, C.M.G., has been appointed a Deputy Assistant Director-General in the Army Medical Service, vice Lieutenant-Colonel H. P. W. Barrow.

MISS IRENE HYLAND, B.A., of the University of Toronto, and for six years dietician at the Bellevue Hospital, New York, is coming to England to serve as dietician with the Harvard Medical School unit in the British Army Hospital Service.

SIR WILLIAM JAMES THOMAS, who has made a donation of £100,000 towards the establishment of a Welsh school of medicine, equipped the Welsh University Medical School at King Edward VII. Hospital, and subscribed £10,000 to Cardiff Infirmary. He received his knighthood in 1914.

DR. ROBERT ROBERTSON, J.P., an Honorary Physician and Chairman of the Visiting Committee of the Royal National Hospital for Consumption, Ventnor, has been unanimously elected a Vice-President of the Institution in recognition of his invaluable services during the many years in which he has been associated with it.

CLINICAL LECTURE

ON

THE CASE OF A COW, A HAT-PIN, AND A BAILIFF.*

By SIR JOHN BLAND-SUTTON, F.R.C.S.

Surgeon to the Middlesex Hospital; Major R.A.M.C.

IN order to make the points in this lecture clear, it will be necessary to describe the anatomical features of the stomach of a ruminant, for the patient was a cow.

The stomach of oxen is very complex (Fig. 1). It contains four compartments: Of these, the first is a large receptacle called the rumen or paunch. The second is a smaller compartment, or recess, closely connected with the rumen and known as the reticulum; this, when cleaned, becomes honey-comb, the choicest kind of tripe. The reticulum receives the food from the gullet.

The third compartment, called the omasum, may be described as a dilatation of the canal between the reticulum and the abomasum; it is ovoid in shape and as big as a man's cranium. The walls of the omasum are thick and muscular, and its mucous membrane is arranged in folds, or leaves. Nearly a hundred folds hang from its dome; they stretch from the œsophageal opening to the entrance of the abomasum. The folds vary in depth (Fig. 2) and produce an appearance like that of the flies of a theatre seen from the stage. These folds earned for the omasum the name of manyplies, and psalterium, from the likeness to a book. Butchers call it the bible.

Ellenberger (1881) investigated the structure and function of the omasum and described it as a triturating apparatus, or masticatory stomach. The leaves near the entrance are furnished with long warts or papillæ, resembling the teeth of a harrow;

After death the omasum is firmly contracted, but the walls of the other compartments of the stomach are relaxed. The stomach generally is under the control of the pneumogastric nerve, but Ellenberger found that stimulation of this nerve has no influence on the omasum. Nerve plexuses and multipolar nerve-cells are present in the walls of the omasum, but no ganglia. The fourth compartment, known as the abomasum, is the true stomach; its glands secrete gastric juice. This acid secretion is called rennet. Dairymaids use the rennet of calves for curdling milk, the first step in cheesemaking.

It is useful to compare the stomach of a calf with that of an ox. In the new-born calf the fourth compartment, or abomasum, is larger than the rumen (Fig. 3). A few months after birth, when the calf feeds on grass, the rumen enlarges rapidly, and in eighteen months the relative sizes of the various compartments are as follows: Rumen, 80 per cent., reticulum 5 per cent., omasum and abomasum nearly equal each other—together 15 per cent. The tooth-like papillæ around the entrance of the omasum are very conspicuous in a calf a few weeks old.

When the cow feeds she encircles the grass with her long, prehensile rough tongue, and tears it off. Moistened with the saliva, the bolus of grass is conveyed by the gullet to the paunch. The fluid in the paunch consists of saliva, which is freely secreted, and water. In the paunch the food is macerated in an alkaline medium assisted by the churning movements set up by the muscular tissue in its walls. Cows, and especially calves, lick and swallow hair from their hides; the churning of the contents in the paunch causes the hair to felt and form balls, often called ægagropiles. The Hospital museum contains some good examples.

When feeding, cows often swallow odd things that may be lying in the grass, such as a frog, a purse, or a tobacco pouch; garters, bracelets, crosses and similar trinkets dropped by lovers; darning needles, knitting needles, sewing needles; crochet hooks, button hooks, wire, forks, nails, blades of knives, scissors, and hymn books. The capacity of a cow's stomach is about 20 gallons.

When the cow has satisfied her appetite, she lies down on one side, generally in the shade; then an apparently involuntary twitch of the flank sends a bolus of grass up the gullet, by reversed peristalsis, into the mouth. This bolus, probably moulded and ejected into the œsophagus by the reticulum, which is capable of energetic contraction, is ground fine by the molar teeth, mixed with saliva, and re-swallowed. This grinding act is known as rumination. The weight of the bolus is about four ounces and the time occupied in each act of rumination nearly a minute. A painstaking observer calculated that the cow spends about seven hours out of twenty-four in ruminating.

When the food returns to the stomach some falls into the rumen, but much of it goes into the reticulum and the omasum, thence onward to the abomasum, where it comes into contact with the

their hard, horny points are so arranged as to hinder the reflux of food to the reticulum. Towards the abomasum the papillæ are shorter, closer set, flattened, and resemble the low elevations of a rasp, or a file. The covering of the leaves is hard, almost horny, and very resistant to dilute solutions of acids, alkalis and peptic juices. The walls of the omasum contract powerfully. Food between the leaves is thoroughly rasped by the papillæ before it enters the abomasum, the true digestive compartment.

* Lecture delivered at the Middlesex Hospital.

gastric juice. The larger portion of the ruminant's stomach is like a pocket, non-digestive.

These facts prove that grass is not digested in the same way as a mutton-chop.

It must be obvious to anyone who clearly grasps the disposition of the various compartments of the stomach of an ox that elongated foreign bodies, such as wire, hat-pins, needles and blades of knives, when swallowed, will have some difficulty in threading the maze offered by the omasum. An

ordinary sewing-needle would easily enter. I have seen one stuck in a leaf of the omasum. Needles and wire often get into the reticulum, and the forcible contractions of its walls cause a pointed body to penetrate and find its way through the diaphragm into the pleura, the pericardium, the heart, or the lung. Sometimes such sharp things are forced into the belly. Such accidents often lead to infective changes that end in death.

Veterinary surgeons who have studied these con-

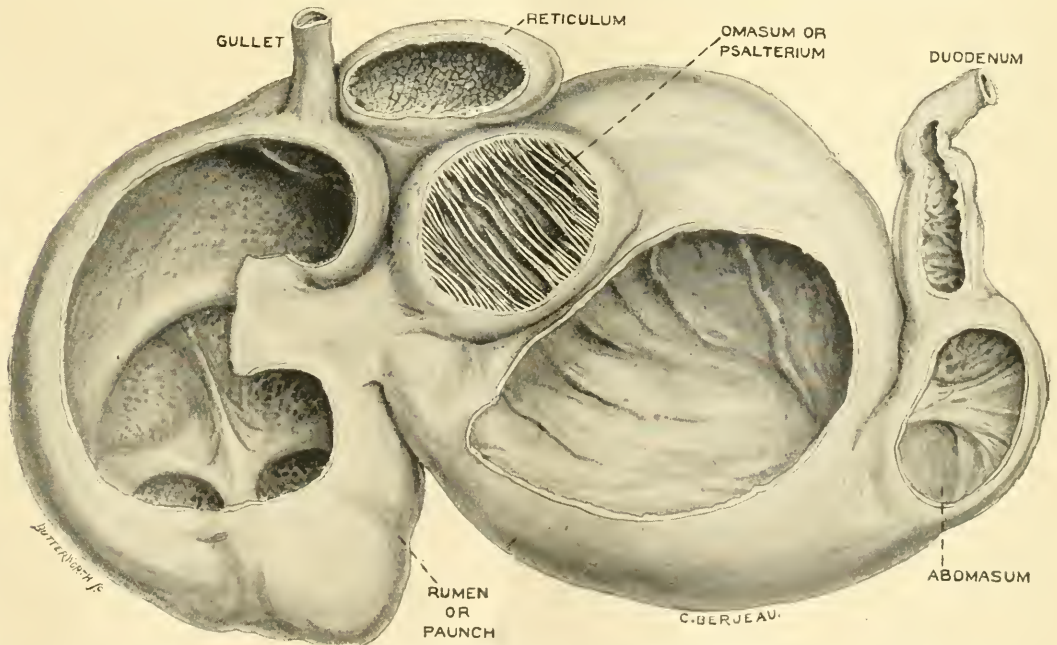

FIG. 3.—The stomach of a calf. The rumen is smaller than the abomasum. (½ nat. size.) (Museum, Royal College of Surgeons of England.)

ditions, realising the frequency with which such dangerous foreign bodies are retained in the reticulum, have approached this compartment of the stomach through an incision in the flank, opened the reticulum and extracted the offending wire, or needle, as the case may be. It is gratifying to know that in a fair number of cases such operations have been successful, not merely in finding and removing the foreign body, but in saving the life of the animal.

THE HAT-PIN.

A charming lady, on her thirtieth birthday, received from her devoted husband a hat-pin surmounted by pearl. Later in the day she visited the mansion of her parents, and as haymaking was in progress, full of glee, all took tea in the hayfield. The lady took off her hat, placed it on the grass and stuck the pin in the ground near the hat. The wind was playful and quietly blew the hat about. When the lady picked up her hat she could not find the pin. Mother, father, sister, servants, hay-makers, male and female, joined in the search. They raked the grass and racked their brains until darkness put an end to the search. The birthday, in spite of the brightness of the day, ended in gloom.

The scene shifts to Christmas. The lady who lost her hat-pin spent the holiday with her parents. On the morning of Boxing Day the bailiff reported that the prize cow was ill and the vet. was puzzled to account for the symptoms. Two days later the cow died and at the *post-mortem* examination the hat-pin was found; it had pierced the wall of the reticulum and entered the pericardium.

The story is clear. The cow, when eating grass, had accidentally swallowed the hat-pin and in due course it penetrated the stomach and inflicted a fatal injury.

THE BAILIFF.

The bailiff, incidentally mentioned in this case, was a peculiar man and attracted my attention two years before the cow episode. The mansion of my friend had large capacious chimneys which served as excellent nesting-places for some jackdaws. There was a disadvantage in this, for when winter came the nests interfered with the escape of smoke and it became necessary to send men on the roof to remove the nests. To avoid this the bailiff had the chimney-tops covered with wire-netting. The following spring the enterprising jackdaws, finding the chimneys closed against them, flew to the stables and turned the pigeons out of the dove-cotes, and there they built nests, laid eggs, and successfully hatched them.

About the time of the cow's death the bailiff's conduct excited comment. When he sent flowers to the mansion they would differ in variety, in colour, or in kind. For example, he would send roses, geraniums and pansies; anemones, hyacinths and daffodils; tulips red, white and blue. In the same way he would send vegetables and fruit for the table, always three kinds. The animals were sent into the fields in groups of three, or of three kinds: cattle, sheep and pigs; a cow, calf and pony; an ox, an ass and a horse. This eccentricity excited comment and amusement. He would send three men to work in a field, or dig the garden; or a man, a woman and a boy. Gradually his master noticed that the fruit trees were being pulled up so that those left stood in groups of three. It then became a serious matter. Finally he began to fell the timber so that three trees stood together. In one field the trees would be an alder, ash and elm; in another, oak, ash and thorn. In one meadow it was fortunate that he spared an interesting thorn that marked the course

of an old road along which Queen Elizabeth rode when she went to the revels at Kenilworth. I have seen that thorn. The cows could ruminate in the shade of the oak, the pony could scratch his rump against the ash, and sheep could leave their wool on the thorn. When the bailiff began to cut down timber trees matters became serious—his sanity was in doubt; then followed a consultation. He was found to be a religious monomaniac. In vulgar language, he was cracked on the Trinity. The poor fellow was incarcerated in a lunatic asylum and died within three months.

ORIGINAL PAPERS.

INFANTILE SURGERY.

INHERITED SYPHILIS IN THE PRODUCTION OF BONE LESIONS.

BY PROFESSOR KIRMISSON, M.D.,

Of the Faculty of Medicine of Paris; Surgeon to the Hôpital des Enfants Malades, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HERE is a case daily occurring in practice, yet one the pathogenesis of which is still being debated. The case is that of a female infant born on June 8th, 1913, so that she is now just over a year old. She was brought by her mother to the orthopaedic out-patient department, and this is what we found.

The child is pale, thin, and looks ill-nourished. She is always moaning, and she displays even to the inexperienced eye the following manifestations of rickets—viz., narrowness of the upper part of the thorax, chondro-sternal prominences: the costal "beads"; a bulky, distended belly, and enlarged joints. The mother, however, especially calls our attention to the arching of the dorso-lumbar region: this is the kyphosis of the rickety young. This kyphosis differs greatly according to the age of the subject. As a rule, in big children, girls of twelve years of age and upwards, it is met with in the dorsal region, or, maybe, spread out over the whole length of the spinal column. This kyphosis of adolescence is accompanied by a compensatory lumbar lordosis.

In infants we often have to eliminate the possibility of Pott's disease, for the rigidity peculiar to this malady may be closely simulated by a state of "contracture" of the little patient at the time of examination. It is, indeed, often necessary to keep the child under observation for a time.

This child at the same time presents a scoliosis, best seen by radiography, with its convexity to the left in the dorsal region and compensatory curves in the cervical and lumbar regions. Lastly, at the posterior angles of the ribs, we find exostoses from the seventh to the ninth ribs on both sides, but more marked on the right. But this is not all, for we also find that there is slight shortening and leg-of-mutton deformity of the left thigh corresponding to a fracture at the junction of the lower two-thirds and the upper third of the bone. The line of fracture runs from above downwards and from within outwards. The two fragments do not override, but form an angle, the apex whereof corresponds to the antero-external part of the thigh. This, the usual arrangement, is due to the action of the abductors pulling on the fragments like the string of a bow. The shortening would be much greater were there any overriding of the fragments. The fracture is not united, as can easily be made out by gently twisting the limb, the movement eliciting soft grating.

Now, this fracture seems to have taken place spontaneously, that is to say, without any appre-

ciable traumatism, on January 7th, 1914. The mother's attention was attracted by the swelling of the thigh and the pain. She brought the child to hospital on the 9th, and the fracture was reduced and immobilised in a tiny gutta-percha apparatus, which is very convenient in small children who incessantly soil the dressings. Then, however, the child had to be transferred to another ward on account of a sharp attack of sore throat with a temperature of 104° F. When the child was brought back to this ward on February 22nd, six weeks later, no consolidation had taken place.

From February 22nd to April 7th continuous extension was applied with a one-pound weight. The deformity of the limb was thus corrected, but some mobility remained, and this had gone on increasing during the last five months.

Now, the child's father is a general paralytic—that is to say, syphilitic. On the other hand, there have been six children in this family, three of whom have died, one a few hours after birth, and the two others, twins born prematurely, reared in the couveuse for six weeks, died at the age of four months.

This case raises a first question—viz., is there any relationship between the rickets and the exostoses? Volkmann, in his monograph on diseases of the locomotor apparatus (in Billroth's "Compendium"), answers this question in the affirmative, and calls these exostoses *rachitis nodosa*. Vesselhagen and others, on the contrary, separate the exostoses from rickets. They hold that the exostoses bring about arrest of development in length, and so cause deformity of limbs with two bones, such as the forearm and leg. Exostosis of the radius determines inflection of the ulna giving rise to a peculiar form of club hand. Similarly, exostosis of the tibia determines incurvation of the fibula and varus club foot. When there is a very big exostosis of the ulna the radius is dislocated at its upper end.

Personally, I agree with Volkmann's theory, and the case of this child militates in its favour. There are plenty of instances in which these exostoses of development are accompanied by manifestly rickety deformities. But to point to a coincidence between rickets and these exostoses does not help us to solve the problem of pathogenesis. We shall have to invoke the influence of the great diatheses—that is to say, either tuberculosis or syphilis, and the most striking features are suggestive of hereditary syphilis.

The influence of hereditary syphilis is admissible in the case of this child on the strength of the father being a general paralytic on the one hand, and, on the other, the polyethality of the mother. This brings up the question whether there is any relationship between rickets and syphilis. You are all familiar with Parrot's patient researches and his not less memorable conclusions. According to this observer, not only is there a causal relationship between syphilis and rickets, but to all intents and purposes they are identical. It was in 1871 that he published in the *Archives de Physiologie* his researches on what he called syphilitic pseudo-paralysis, since known as Parrot's disease.

He described certain juxta-articular changes which, in his opinion, gave rise to this complexus which has as its seat of election the lower end of the humerus. Osteophytes form, between the bone and the periosteum, true chondro-calcareous formations, which undergo gelatinous infiltration entailing a fragility that finds expression in separation of the epiphyses and spontaneous fractures.

Parrot's disease, he it remarked, does not justify as gloomy a prognosis as was believed by its dis-

coverer. I have seen a great many cases of the kind, and I have never seen death result. Two elements must be distinguished—the osseous lesion *per se* and the superadded suppuration by infection, and the latter may, of course, cause death in a debile subject. When the lesion is in course of repair, this chondro-calcareous layer undergoes a sort of hypertrophy, and we get actual nodules similar to those ascribed to rickets.

In this way Parrot concludes in favour of the identity of the bony lesions of hereditary syphilis and rickets. At present, however, this doctrine can no longer be subscribed to. I will concede that we daily meet with children presenting rickety deformities without any history of syphilis, but the fact remains that rickets is met with in practically all syphilitic children. Pinard remarks that "almost all children with rickets are the offspring of syphilitic parents."

Hereditary syphilis is not the sole and only cause, but it is a cause of rickets in a large number of cases. Such appears to be the case in respect of this child, our little patient, in whom we note the coincidence of hereditary syphilis, osteogenetic exostoses and rickets, so that the existence of a relationship between these lesions and hereditary syphilis is quite admissible.

And what about the fracture of the left thigh? You know that this is the fracture *par excellence* of young infants. Fractures of the upper limbs belong to the second period of childhood, between seven and twelve and onwards. Of 100 cases of fractured thigh 80 are to be found in the Baudelocque Ward—that is to say, they are in children under five years of age. It is rather more frequent in boys than in girls, no doubt on account of the greater muscular development of the former.

In this instance the fracture, if the mother is to be believed, occurred spontaneously—that is to say, in the absence of any outward visible traumatism. On the other hand, there has been no union after the lapse of nearly six months, whereas in fractures in young children we usually get firm union in about three weeks. If we were unaware of the child's antecedents we might have attributed the non-union to rickets, for it is certain that rickets, especially in the atreptic forms described by Parrot, is often responsible for delayed union of fractures.

But the general paralysis of the father and the polyethality of the mother justify us in suspecting hereditary syphilis. It is true that the child does not present any of the obvious stigmata (teeth, eyes, ears, skin, and mucous orifices), but that does not oblige us to reject the syphilitic hypothesis, as is shown in the following case:—

Not long since, in discussing palatoplasty, I had occasion to refer to the case of a young adolescent in the Bouvier Ward who presented a cicatricial adhesion of the soft palate to the posterior laryngeal wall. Now, this patient was cured by specific treatment, yet there was no history of syphilis in his person or in his family. It would have been necessary, of course, to have had the child under observation from its birth onwards for us to be able to affirm that there had never been any lesions suggestive of syphilis, but, as you are aware, there is such a thing as delayed hereditary syphilis. As a matter of fact, we not infrequently meet with ulcerated sore throat characteristic of heredo-syphilis in subjects upwards of twenty years of age who have not been exposed to contamination acquired.

This is why we placed our little patient on a treatment comprising mercurial inunctions and the administration of Gibert's syrup (iodide of mercury), the fractured limb being at the same time placed in extension by means of a Liston splint.

EXOPHTHALMIC GOITRE.

SYNONYMS: GRAVES' DISEASE;
BASEDOW'S DISEASE; HYPER-
THYROIDISM.By IVO GEIKIE COBB, M.D., M.R.C.S.,
L.R.C.P.,

Late Assistant to Out-patient Physician, the Middlesex Hospital.

WITH increasing knowledge, the conception of this disease has become a much more difficult matter than when it was regarded as being solely due to an overaction of the thyroid gland. Modern views as to the pathology of Graves' disease would have us believe that, although derangement of this gland is present in this malady, the thyroid is not the sole organ at fault, neither is a hypersecretion of this gland alone responsible for the symptoms.

Let us for a moment refer to some definitions of this condition which have been current, and then compare these with modern views as to the aetiology and pathology. In one text-book of medicine we meet the following definition: "A disease characterised by enlargement of the thyroid, exophthalmos, increased action of the heart, tremor and nervous instability." (1) Again: "The four classical symptoms of Graves' disease are: a staring appearance of the eyes, generally spoken of as exophthalmos, though there need be no actual protrusion of the eyeballs; moderate and almost symmetrical enlargement of the thyroid gland; a pulse-rate between 120 and 180 per minute—usually about 140 when the attack is moderately severe; and extreme nervousness, with fine tremor of the outstretched fingers. When all these symptoms are present at the same time, there can be little doubt as to the diagnosis, but very often some of them are absent, and it is possible for tachycardia to be the only symptom of the disease. . . ." (2) ". . . There are three prominent symptoms: protrusion of the eyeballs, enlargement of the thyroid gland, and frequent action of the heart." (3) "We are accustomed to recognise three cardinal symptoms in this disease—namely, (1) tachycardia, (2) goitre, and (3) exophthalmos; but we must remember that these are not the only symptoms." (4)

These definitions represent the general views which have been held on the nature of the disease, and on the most constant symptoms.

The condition was first recognised by the celebrated Dublin physician whose name it now bears, about the year 1835, although v. Basedow in 1830 published a paper on the subject. Consequently, the disease is in Germany and some other parts of the Continent still referred to as "Basedowsche Krankheit," or "Von Basedow's disease." However, as early as 1825, Caleb Parry, of Bath, drew attention to the condition, and, according to Osler, to him belongs the credit of first describing the disease. Many of the early conceptions of the malady have, in the fulness of time, given place to views which have been promulgated from the results of the extensive practical physiological research which has been undertaken in order to establish the causation of the disease. But it was recognised then, and it is believed now, that emotional strain can precipitate the disease. Thus, Trousseau refers to a lady who was suffering great grief at the death of her father, and had been crying for a long time, "suddenly felt her eyes swell and lift up her eyelids"; this was accompanied by copious epistaxis, violent palpitation, and throbbing and enlargement of the thyroid. A few days later the nature of the disease was recognised. Again, Stokes describes the case of a man who developed the disease from long-continued bleeding from piles; and many other

records show that the aetiology of the disease was universally regarded as a wide one.

From the early thirties of the last century the nature of the condition was recognised, but it is only comparatively recently that the diagnosis has been narrowed. Thus, it will be seen from the definitions quoted above, that it is not necessary, as used to be thought, for all the classical symptoms to be present in any given case. Nevertheless, there is one symptom without which, as Mackenzie rightly insists, the condition cannot be diagnosed, and that is persistent tachycardia.

So we come down to this: that exophthalmic goitre may, and in the opinion of many observers does, exist without the exophthalmic symptom. It is, therefore, somewhat unfortunate that the name of the disease should be inseparably connected with a symptom which is by no means constant. But we cannot, at the moment at any rate, suggest any other name which is free from objection. As we shall see later, the modern nomenclature which is sometimes used—namely, "hyperthyroidism," is open to an equally serious objection, as it implies that there is always an overaction of the gland, and that it is this overaction alone which is responsible for the features of the disease, of which we must reckon proptosis, when present, as one. Again, it has been pointed out by one observer that this latter symptom is significant of overaction, not of the thyroid, but of the adrenals. (5) Therefore, hyperthyroidism is a no more suitable label for the disease than is exophthalmic goitre. Although there seems to be an objection to utilising the name of the discoverer of a disease to designate that disease (*a*), in the present instance it would seem, for the moment at any rate, to be the most satisfactory way to designate this malady. "Graves' disease" has the merit of being non-committal as to symptoms, and less unwieldy than many of the other names by which the disease has been known.

In the majority of text-books, the malady under discussion is referred to as "exophthalmic goitre" in contradistinction to ordinary goitre. When the swelling in the neck, if present, is accompanied by the other well-recognised signs of Graves' disease, such as persistent tachycardia, exophthalmos, tremor, and other symptoms and signs to be described anon, then we diagnose the presence of this disease as opposed to simple goitre.

Graves' disease, as we shall call this malady in this article, is seen more commonly in the female sex than in the male, and more commonly in young people than in elderly. It has been seen, however, in an infant only 2½ years of age; and several cases are on record of the disease occurring in children of both sexes. Von Graefe stated that the proportion of females to males was six to one; while Eulenburg said that the ratio was at least two to one. Trousseau's cases show a ratio of fifty to eight, Henoch's twenty-three to four, and Præel's twenty-eight to one. Whatever figures we study, there is plainly a vast preponderance of females over males. The commonest time for the disease to develop is in the decades 20-40, and its features are often made manifest at critical times in the history of the patient, such as puberty, the catamenia, and the menopause. Indeed, it is said that in normal persons of the female sex, the thyroid is liable to

(a) It may be affirmed that this mode of naming a disease after its discoverer is to be deprecated, partly on account of the difference of opinion as to whom the credit of the discovery really belongs to, and partly because it is perhaps an unfortunate reward for the happy pioneer in the particular disease. Again, if a disease is discovered more or less synchronously by different observers in different countries, a nomenclature is adopted which varies with the different countries, and this all leads to confusion. If a disease is called by its most distinctive feature, this will probably be similar in different languages, so where such a course is possible, it is certainly to be preferred.

swell and to exhibit increased vascularity at these times, and during sexual excitement.

As we have already indicated, there can be little doubt that, certainly in individuals prone to the disease (by this I mean persons who exhibit signs indicative of thyroid instability), a mental strain or a sudden anxiety seems to be capable of precipitating the disease. Again, there is a sufficiency of evidence to show that a parenchymatous goitre can develop into an exophthalmic goitre, given suitable opportunities. The symptom-complex which is produced by thyroid feeding on a large scale differs in many details from the symptom-complex of this disease, so, as Biedl says, we must regard the similarity of the two pictures not as conclusive evidence that the thyroid is the organ responsible for the disease, but as very strong presumptive evidence.

When we come to study the symptoms of Graves' disease, we see three or four definite and fairly constant features, and a multitude of smaller and somewhat vaguer signs. There can be little doubt that tachycardia deserves the first mention, as it is very constant and may be looked upon as a fundamental sign of this disease. Indeed, it is one of the symptoms which can always be produced by the ingestion of thyroid extract; and there must be very few cases of undoubted exophthalmic goitre which do not show this sign. The pulse is usually rapid, ranging from 100 to 140 or more per minute. The pulse-wave is not always thin; indeed, in many cases a full and bounding pulse is observed. Again, it is usually regular, but the rate increases upon very slight exertion.

In this connection, it is interesting to refer to the theory which Eppinger and Hess brought forward. They consider that the symptoms seen in Graves' disease enable us to divide these cases into two groups. In the first, the symptoms of sympathetic excitement predominate, and these they describe as sympathetico-tonic; while the second group is described as vago-tonic, from the fact that the symptoms seem to proceed from disorganisation of the autonomous system. "Falta, Eppinger, and Rudinger assume a polyvalency of the thyroid secretion, and they regard the hyperthyroidism of Graves' disease as the outcome of a simultaneous though probably independent stimulation of both the sympathetic and autonomous nervous systems."⁽⁶⁾

There seems to be little doubt that tachycardia is only one of the many symptoms seen in this disorder which can be justly attributed to the sympathetic nervous system. We shall refer to these later.

The symptom which merits consideration next is the local enlargement of the thyroid gland. Although not so constant as tachycardia, it is nevertheless present in the majority of cases of this disease. The thyroid is generally moderately enlarged, the right side being perhaps more so than the left. In some cases, however, the enlargement is scarcely perceptible, while on the other hand it may be very great. In the early stages the gland is soft and elastic from vascular engorgement, but later it becomes harder from fibrous hyperplasia.

Histologically, the gland presents a picture of diffuse enlargement, with a great increase in the vascular supply. There is definite new formation of tissue, which runs hand in hand with certain retrogressive processes, notably cell desquamation. Young follicles are seen associated with older cells, and in the latter may be seen breaking-down processes. As a rule a thrill can be detected, certainly in the larger tumours, and as the disease progresses, the thyroid may alter in size, diminishing in favourable cases. It is said that in some ways the thyroid

enlargement in Graves' disease is characteristic; and Erdheim maintains that the young cell formations with fat granules are characteristic of Graves' disease.

For a long time the proptosis was looked upon as an essential feature of this disease, and it is only recently that we have come to realise that it is by no means always present. Its origin, or rather the changes which underlie the exophthalmos, are still unknown. It has been suggested that the proptosis is due to a deposit of fat behind the eyeballs; to a venous congestion in the posterior part of the orbit; to dilatation of the retro-bulbar arteries; or to contraction of Müller's muscle. It is pointed out that the sympathetic system is largely connected with the symptoms of this disease, and that a disorganisation of this system will account for many, indeed for most of the features, always excepting the changes in the gland itself. On this theory it is much more probable that the proptosis is due to circulatory changes than to either a contraction of Müller's muscle or to a deposit of fat in the orbit.

There are certain classical signs which one is accustomed to look for in association with the exophthalmos, and we must briefly refer to these. The widening of the palpebral fissure gives an appearance of great protrusion to the eyeball, and this is partly due to the retraction of the upper lid. This is known as Stellwag's sign. Although the eyeball in many cases appears to be prominent, it is in reality less so than it appears, on account of the uncovering of the eyeball due to the retraction of the upper lid. There is also a diminution of the reflex excitability of the eye, so that there is less irritation of the globe than would otherwise be the case. Another sign in connection with the lid is known as Von Graefe's sign, and consists in a lagging of the upper lid behind the globe during the downward descent of the eye.

Sometimes there is an insufficiency of the internal recti muscles of the eye, as a result of which convergence of the eyes in near vision is imperfect (Möbius). Occasionally blepharoclonus is present.

Tremor is another constant sign of Graves' disease, and is quite characteristic. It is usually very fine, and confined to the hands, although occasionally it is seen in the muscles of the trunk, so that by laying a hand on the shoulder or trunk the observer can feel a quiver of the whole body. (Oppenheim.) The tremor of this disease is usually excited by movement or by nervousness, but is also present during rest. The rate of movement is somewhere about nine per second, and can best be seen when the patient extends the hands with the palms downwards.

Before turning to the discussion of the mental changes present in Graves' disease, there remain a few less constant symptoms and signs which we have to mention. These may be classed under the headings: vasomotor, secretory, and trophic. The subject of Graves' disease is very liable to suffer from profuse perspiration—indeed, in some cases this amounts to a definite hyperidrosis. As we stated in a previous article, these patients feel the heat greatly, and naturally this symptom is worse in hot weather. The sweating may be more or less local, or it may be general. One point of interest in this connection is with regard to the electrical resistance of the skin in cases of Graves' disease. Vigoroux first discovered that in patients suffering from exophthalmic goitre the electric resistance of the skin was diminished. This is now generally believed to be due to the undue moisture of the skin owing to the increased sweating.

Flushing of the skin, quite irregular in distribution, erythemata of a patchy nature, pigmentation

—particularly of the margins of the lids of the eyes, and sometimes as marked as that seen in Addison's disease—are all phenomena of this condition. As is well known, there is a tendency to loose evacuations of the bowels, sometimes of actual diarrhoea; while the secretion of urine is also increased. The digestive system is often upset, and attacks of sickness, with bulimia or, alternatively, loss of appetite, are about equally common.

The reflexes are often altered; more usually increased, although they may be diminished, or even in rare cases absent.

Cases are occasionally encountered in which the symptoms present a strange combination of those seen in exophthalmic goitre and those characteristic of thyroid deficiency. Thus, patches of lipomatosis are met with in a typical case of Graves' disease; while occasionally the condition of the skin approximates much more nearly to that typical of submyxœdema. Leonard Williams believes that there is often, if not always, a combination of excess and deficiency in this disease. Again, some of the symptoms which we are accustomed to regard as indicative of disease in the chromaffin system, such as pigmentation, would suggest the presence of a combination of thyroid and adrenal disturbance.

But as important, or nearly as important, as the physical symptoms of this complaint, is the mental change which characterises exophthalmic goitre. The main features of the sufferer from this disease are well known, but perhaps a brief sketch of the mental make-up of the patient may be useful. Whatever is the agent at work in these cases, whether the disturbance is originally in the sympathetic system, or to be attributed to an excess of thyroid secretion due to a cause or causes unknown, it is one fraught with evil for the peace of mind both of the patient and her relatives. From being gentle and docile, it may be, she changes to an intractable, selfish, restless, and inconsiderate being. The medical attendant as a rule receives the full benefit of this, and little he can do is right. He is either old-fashioned when he explains that the reason for rest in bed, for example, is to avoid straining an already weakened heart; or an ignoramus if he insists that rest combined with hygienic principles offers the best hope for alleviating the disease. If he suggests trying a new remedy he is experimenting with her; if he persists with the old he is a "stick-in-the-mud."

Perhaps the saddest of the changes wrought by this disease are the changes for the worse in the psyche, and it behoves the medical man to be very tactful with such patients and to remember that the mind is the victim of a disordered bodily functioning, and is no more to blame for its vagaries than the victim of, let us say, puerperal mania.

The mental symptoms are, like the physical, capable of entirely clearing up; but even so, Leonard Williams doubts whether the individual is ever quite the same again. There can be little doubt that this disease plays havoc with the patient's character. It changes the quiet to the restless, the unselfish to the self-centred, and the amiable to the perverse. That these patients are notoriously difficult to treat is well known; that they make the treatment of their condition doubly difficult by their attitude to what is being done for them is almost equally well realised by everyone connected with the case except the patient herself.

Apart from the changes in character which we have outlined, more serious symptoms are seen in connection with Graves' disease. Apart from actual insanity, such as melancholia, mania, hallucinatory confusion, and obsessions, there are the minor changes which are apt to lead to these more

serious psychoses. Thus the patient is excitable, wildly restless, sleepless, and confused. She is incapable of organised thought, of successful memory, or of attentive control; while her general mental habits have been well spoken of by Reynolds as "mental chorea." It is quite obvious that it is but a short step from this stage to that of insanity.

Needless to say, fortunately only a relatively small percentage passes from the mentality characteristic of Graves' disease to that typical of insanity. Nevertheless, the picture we have drawn of the mental condition of these sufferers is not exaggerated. It is true that in many diseases which the physician is called upon to treat to-day, the patient's worst enemy is himself; and in no disease is this more true than in exophthalmic goitre. Consequently, it is no rare occurrence for such a patient to pass from one doctor to another, giving no one a fair chance to benefit the malady. This is the analogue in the mental apparatus of the restlessness in the physical system which prohibits the patient from resting, which is the one thing most to be desired. Thus is his temperament at the time his worst enemy, and it is this which needs treatment quite as much as the syndrome of symptoms which we have been discussing.

Such, then, is the bare outline of what constitutes Graves' disease. What is the prognosis, and what can we do to benefit that part of suffering humanity afflicted with Graves' disease?

First, as to prognosis. The course of the disease is very variable: it may, in rare cases, be rapidly fatal, or it may linger for many years, sometimes showing improvement, at other times retrogressing. MacKenzie gives the mortality at approximately 25 per cent. In patients who eventually recover, there is often a period when no improvement seems to take place, and the disease seems to be stationary. Even in these cases there is a prolonged convalescence, and sometimes years afterwards some slight trace of the disturbance can be found.

In the early stages, the malady is very liable to be diagnosed wrongly, some such diagnosis as neurasthenia being made. This probably partly accounts for the advances which this disease makes in early stages, owing to a misconception of the nature of the trouble. Also, the prognosis must be based upon the length of duration of the disease, the prominence of individual symptoms, the means of the patient, and, last but by no means least, the degree of mental abnormality which exists.

But, speaking generally, patients who have had the disease for a long time, especially where treatment has been of little avail, are not the most hopeful of subjects, and there seems little reason upon which to base hopes of complete recovery. Indeed, in such cases as these, it is doubtful whether they are ever entirely restored to the *status quo ante*. Although it is usual to see amelioration of the symptoms, even a vanishing of the proptosis, or at least a diminution of the amount of protrusion under successful treatment, such patients are extremely liable to a relapse. Their nervous symptoms recur from time to time; indeed, it would seem that it is very difficult for them to return to the successful functioning of this system once Graves' disease has developed.

There have, however, been many reports of recovery of long duration. Cheadle reports recovery lasting twenty years; while Oppenheim says that in one case of his recovery lasted "for twenty-seven years, in another for eighteen, in four for six to eight years." (7) The chief difficulty lies in keeping up the faith of the patients, in exacting obedience, and in counteracting individual symptoms.

Sudden death has taken place during the course of this disease, and when we remember the strain

upon the circulation, the dilatation of the heart and the disorganisation of the neuro-musculature of this organ, it is not to be wondered at. Occasionally, as a sequel to this malady, atrophy of the thyroid may take place, with resulting myxœdema.

We shall have to refer at some length to the treatment of this malady, for it necessitates a discussion of methods which have been utilised for many years, as well as those which have found favour recently. Modern physiological research has enlightened us upon many points in this connection, and some of these have pointed to different methods of treatment, a few of which, at any rate, have shown signs of success.

But whatever treatments we may initiate, whether we incline to the old practice of counteracting the symptoms by controlling the exuberance of the heart's action, by producing adequate sleep, by anointing the thyroid gland, or by countless other small attentions, one factor remains constant, and that is the insistence upon sufficient rest, even complete rest in bed in bad cases. The application of the principles of general hygiene cannot be insisted upon too firmly, for this should be the bed-rock upon which all subsequent treatment is based. The difficulty is that the restlessness which these patients so often exhibit makes this stipulation a difficult matter to enforce. Nevertheless, it is not so much a matter of the practice of medicine as of the practice of common sense which suggests this; for it must be obvious that exertion, particularly undue exertion, which is always followed, as it is in this disease, by an increase in the symptoms, must be wrong, and therefore in no circumstances to be considered. When tachycardia is present, as it invariably is, our first aim must be to reduce the work of the heart to a minimum, and in doing this to reduce the tachycardia. Even if the rate of the heart's action is not excessive, the patient must be made to take periodic rests in the course of the day. She should rise late and retire to bed early, resting after meals, and avoiding hurry and perturbation. Where tachycardia is a marked feature, and more especially where the signs of general debility with marked loss of flesh are evident, complete rest in bed is essential.

There can be little doubt, moreover, that these patients require every hygienic advantage which can be given them. Thus, where possible, they should reside in the country or by the sea, but not in too bracing a place. They should rest in the open air, lie in the sun for the greater part of the day, and attempt no exercise of a strenuous nature. I have on several occasions had occasion to emphasise the harmful effects which absence of rest has produced; but it is often extremely difficult to make the patient understand this. Again, the diet must be regulated to the individual case, and with some thought to the nature of the disease. Thus, we must bear in mind what underlies this malady, especially what has been discovered in recent years. Firstly, the condition of the gastro-intestinal tract must be considered: if the digestion is good, and there is little tendency to diarrhoea, vegetables may be permitted, but this item of diet must remain under the control of the medical attendant.

Again, in this connection we should bear in mind another important fact—namely, that iodine is excessive in the colloid in Graves' disease, and is also contained in most vegetables. Therefore, we do not want to add to the amount already present in the body. In this connection Rendle Short says: "We see also that exophthalmic goitre is due to hypersecretion of the iodothyron, as is proved by the artificial imitation of the disease by excessive thyroid feeding, by the excess of iodine present in the colloid in Graves' disease, and by the character

of the histological changes. Thus we have reason to expect good from partial removal, which has been very successful in the hands of Kocher, the Mayos, and others. It would be reasonable also to try the effect of iodine starvation by eliminating vegetables and ordinary tap-water from the dietary, and substituting for the latter the water of a goitre well. It is well known that exophthalmic goitre and parenchymatous goitre show a sort of geographical antagonism, and the effect of the water in reducing the amount of iodine for conversion into iodothyron would be valuable."(8)

It must be borne in mind that parenchymatous goitre is supposed to occur owing to a deficiency of the iodothyron, so that the thyroid hypertrophies in an endeavour to supply that deficiency. If, therefore, there is too little of this element in the thyroid of sufferers from parenchymatous goitres, they may be helped by the ingestion of vegetables. The water of the well-known goitre wells is supposed to produce parenchymatous goitres by containing a substance which deprives the body of the iodine by forming a combination with it. In an effort to counterbalance the diminished output of iodine the gland hypertrophies. On this assumption, then, it is recommended to try the water on patients suffering from exophthalmic goitre, in the hope that the unknown substance in the water will utilise some of the excessive secretion of the thyroid.

Turning now from the consideration of the general treatment of this disease, we find a host of other remedies which have from time to time been recommended. Apart from symptomatic remedies, over the consideration of which we shall spend but little time, we have before us a choice of many drugs, both for internal and external application. Of these, preference seems to lie with belladonna, aspirin, the salicylates, arsenic, and iron salts (where indicated). As we have already said, Graves' disease is often associated with anæmia, and therefore some benefit may be expected by the administration of these latter salts.

Of cardiac tonics, some authorities prefer strophanthus, while others recommend digitalis and nuxvomica. But the help which the physician may expect from these drugs is strictly limited to their local action upon tachycardia.

Leonard Williams has reported good results in several cases from the hypodermic or intramuscular injection of bile salts. The *rationale* of this treatment lies in the fact that it is well known that these salts circulating in the blood produce a sedative effect on the brain and a slowing of the pulse.

Of recent years, more and more stress has been laid on the chance of finding an organo-therapeutic compound which will help to neutralise the excessive action of the thyroid. Extracts of the adrenals have been tried, as also the extracts of pituitary, the ovaries, the parathyroids, and the spleen. Unfortunately, these have not given good results, only the parathyroid holding out any hope in this direction.

But there remain several external remedies to mention, some of which have been stated to give really good results in some cases. Of these, the X-rays is very well spoken of when applied to the exterior of the gland, and it has been said on many occasions to have limited the exuberant activity of the thyroid. Again, galvanism and faradism, applied either to the gland itself or to the sympathetic in the neck, has been tried, sometimes with success. Or, a compress of adrenalin applied to the goitre is a help in some cases. I have had good results in some patients from the application of a mercury ointment to the thyroid. A small portion rubbed in every night, associated with other internal

treatment, has on more than one occasion resulted in an amelioration of the symptoms.

Again, since 1884, preparations have been manufactured from thyroidectomised animals. Of these the more important are "antithyroidin" (Moebius), "hæmato-éthyroidine," and "thyroidectin." Beebe has evolved a method of treating Graves' disease by an antiserum produced by the inoculation of a thyroid preparation in animals.(9)

It is too soon to speak of the results of this latter treatment, but its value is said to have been proved in a large number of cases.

In conclusion, we must emphasise the fact that, of all diseases which the medical man is called upon to treat, probably no one makes such calls on his perseverance and patience. For he has to treat an irresponsible patient, and one who is not the best judge of her condition. He requires infinite tact and an everlasting patience, if he is to see the fruits of his labours. Furthermore, he must perforce try any remedies which hold out a chance of help, and he must discriminate nicely between those which are logically futile, and those which are based upon reason.

There is some ground for hoping that in the near future, as our knowledge of the disease and its causation widens, we shall evolve a more satisfactory mode of treatment. For the present, we must make up by our resourcefulness what we lack in our nicety of knowledge.

(The next article in this series deals with "Thyroid Deficiency." The previous articles in this series appeared in the MEDICAL PRESS AND CIRCULAR on May 24th and June 7th.)

A NOTE ON LEISHMAN'S BODIES : PERNICIOUS ANÆMIA : CANCER.

By JOHN FURSE McMILLAN, L.R.C.P.LOND.,
M.R.C.S.ENG., L.S.A.,
Late R.A.M.C.

WHILST engaged in the study of sleeping sickness and trypanosoma in one of the standard text-books on Bacteriology (a), the writer was struck by an illustration of those adventitious bodies or individuals which are to be found in microscopic examination of the blood of those suffering from certain diseases peculiar to the West Coast of Africa, Palestine, Mesopotamia, Egypt, and the Military Cantonment of Calcutta—Dum Dum, with perhaps other localities.

In 1882 the writer was House Physician to Dr. Coupland at the Middlesex Hospital, and as the latter was engaged in the investigation of the hæmic changes in anæmia, it fell to his duty to prepare certain specimens, from the ordinary case of anæmia peculiar to the housemaid or shopgirl, to those of pernicious anæmia. In the former case there was little to be detected microscopically other than an alteration in the quality of the blood, whereas in the latter were to be seen what would appear to be adventitious bodies, caused by amorphosed rouleaux of red blood corpuscles enclosing disintegrated leucocytes embedded in plastic fibrin—a description that may sound to the

(a) Muir and Ritchie.

modern ear somewhat old-fashioned, but which, considering that the cachexia of pernicious anæmia bears the same relation to the cachexia of cancer as does the cachexia of malarial fever to the so-called Dum Dum fever, renders it obvious that an investigation of cases of pernicious anæmia and a comparison with those of Dum Dum fever and its allied diseases would possibly throw some light not only on the cause of the pernicious forms of anæmia, but also on that of cancer, given that the modern bacteriologist discovers an association between the Leishman bodies of Dum Dum fever and those adventitious bodies that are to be found in cases of pernicious anæmia. At any rate, the very name of cachexia implies blood change with ultimate deterioration, and inasmuch as malaria is due to a specific adventitious organism which brings about this status; whilst Dum Dum fever is due to another and separate organism, also bringing about cachexia, as regards cancer, especially in so far as concerns epithelioma, given a certain condition of the blood either due to the presence of such bodies as Leishman's, which after the manner of the bacilli of yellow fever, may leave the capillaries by a process of osmosis (a), and so be undiscernible under the microscope, then here we see how, apart from the ever-present question of heredity, which may be regarded as bearing the same relation to the bacteriological question as does the family history to the physical evidence of a case, the cell proliferation of cancer may occur; which, whether we denominate as cause or effect, in its redundancy is the concomitant of asthenic death.

Then, in so far as concerns cancer, it may be that heretofore we have mistaken cause for effect—that is to say, an examination of the blood of a cachectic, *in initio*, may reveal to the bacteriologist the cause, before osmosis has occurred, in that position of the body constituting a nidus. For we know that the lymphatics are *not* the primary site of the growth of cancer; but that the nidus will occur where there be some exciting cause, such as a sore on the lip in the case of epithelioma, excoriation of the nipple as to scirrhus of the breast, and erosive indigestion as to scirrhus of the pylorus; whilst sarcoma is for the most part concerned with the sexual functions of women, such as, in whom, may occur anæmia.

So that on the first appearance of a cancer, it would appear well for the bacteriologist to examine the capillaries in the region of the commencing growth with a view to the discovery of bodies allied to those of Leishman.

MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My last letter was occupied with the opening of an account of what I defined as the attempt that was made in 1858 to provide the profession with a complete legal constitution; I gave an account of the magnificent work carried out by the General Medical Council under the Act of 1858 in improving by education and examination the personal and professional qualities of the medical man, and I deplored the complete lack of political power possessed by this great profession. This lack of power has been mainly due to the default of the British Medical Association. It has included a membership of sometimes over 20,000, and it has

from first to last entirely failed in one of its prime duties—namely, that of gathering in and voicing the opinions of this vast body. It is my belief that if the Association had brought to bear the great latent power it contained, complete reform of medical law, including the control of quack medicines, might have been brought about many years ago. At this moment the profession, as a mass, has no political power in any direction in which it is entitled to it, and is either ignored or even treated with contempt by statesmen and the Legislature.

After the control of education, the next function of the General Medical Council is registration. Registration is not compulsory; but an unregistered man cannot occupy any post under Government, and cannot recover fees by process of law. The Council can take cognisance of disgraceful conduct on the part of any legally qualified man. It can hale before it a practitioner charged with an offence, and can admonish him, suspend him, or strike his name off the Register if convicted of infamous conduct. Having struck off the name, the Council has no power whatever over the offender. He can go on practising the profession; he can adopt bogus titles; he can add to his name the degrees he possesses, merely adding the prefix ex—as, for example, ex-M.R.C.S., L.R.C.P., and he can with impunity use language in his advertisements clearly implying that he still remains a legally qualified medical man. The Council has no power whatever to interfere with unqualified practitioners, nor to prosecute quacks assuming titles who possess no diploma. The preamble of the Act of 1858 contains the declaration that it is intended to enable the public to distinguish between qualified and unqualified practitioners. This, of course, implied the prevention of the assumption of titles by unregistered persons, and punishment was prescribed for offenders. It was not long after the passing of the Act that magistrates began to hesitate in imposing fines under the Act, and after a long series of cases of various kinds which were passed to the higher Courts and the House of Lords, it was found that the penal clauses intended for the protection of the public could not be enforced. This deplorable fact was announced by the President at an opening of a session of the Medical Council a few years ago. Many swindlers using the title "Dr." have passed before the public view within late years without interference from medical law, and there still remain great numbers of fraudulent quacks who, if they do not actually use medical titles, employ in their advertisements language calculated to make even educated people look upon them as *bona fide* medical men. In passing, I should like to mention that a similar weakness has been displayed in the Dentists Act. An unqualified man may not assume the title dentist, surgeon-dentist, or dental surgeon, but he may use the words dental surgery or dentistry in his advertisements and on his signs, and deceive the public into the belief that he is a registered dentist. The latest attempt at protective legislation of this kind, the Veterinary Act, has broken down more or less completely in a similar fashion. That the defects in the Medical Act of 1858 might be easily remedied is evident. The law which governs the profession of solicitors is completely effective. The Law Society has ample power to enforce the most rigid discipline on registered men. It has power to prosecute any person even remotely pretending to qualification. Persons not on the Rolls practising as solicitors are not to be found, and any man of business who should write a letter suggesting even faintly that he was a solicitor makes himself liable to punishment. The law is clear; magistrates never hesitate to convict, and no case has for years been taken to the Higher

Courts. What has been done for the solicitors can evidently be done for the doctors. Moreover, the protection of the public against imposture has been provided in at least one of our Dominions. An illustrative case within the last year or so is to be found in the Law Reports. The Transvaal Ordinances forbid the practice of any department of medicine or surgery to unqualified men. An offender was convicted and fined by a Court of Summary Jurisdiction. He carried his case through all the Higher Courts up to the Supreme Court of South Africa. These Courts all confirmed the judgment of the magistrates. Not content, the applicant came to England and brought his case before the House of Lords. The supreme tribunal upheld the decisions of the Courts below. The elaborate judgment of the Lords is to be found in the Law Reports. It showed the unequivocal character—the unmistakable plain English—of the Transvaal Ordinances. It is surely not beyond the power of British Parliamentary draughtsmen, perhaps with the help of the General Medical Council, to amend faulty clauses of the Act of 1858, and there cannot be the least doubt that if the evils that have been continued for so many years through the weakness of the Act of 1858 had been put forcibly before the Legislature the proper remedies would have been long ago applied. The British Medical Association has been all along the only body capable of pressing upon the Legislature the necessity for medical law reform, and if it has tried it has entirely failed to obtain a hearing from statesmen or from Parliament.

I have not yet concluded my argument, but must once more stop in consideration of your space.

I am, Sir, yours truly,

The Old Rosery,
Earlwood Common.
June 8th, 1916.

HENRY SEWILL.

THE PROGNOSTIC SIGNIFICANCE OF A COPIOUS RASH IN TYPHOID AND SIMILAR INFECTIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with much interest and pleasure the article by Professor Gougerot in the MEDICAL PRESS AND CIRCULAR of June 7th. I have for years held that the defensive reaction as shown by eruptions on the skin has not received the attention it deserves. I am convinced that dermatologists are in a great measure to blame for this; they have for ages worked from without in, instead of from within out, as they ought. By means of ointments and lotions they calm the reaction in the skin, and so "drive in" the germs and toxins. One of their pet arguments is that a healthy skin acts better than a diseased one. So it does; but they seem to forget that in nine so-called skin diseases out of ten the whole body is diseased, and the organism has created open doors in the skin through which germs and toxins may be driven out away from the brain, spinal cord, heart, lungs, etc. I believe it is a matter of common observation that locomotor ataxy has never been seen in a syphilitic patient who has developed pronounced cutaneous eruptions. Why, then, should these open doors be closed? I could many a tale unfold in this connection if I chose, but this is scarcely the time to do so. Also, Lister played a great part in stamping out the fine old remedies, such as the blister followed by savin ointment, the "crisis" as used with magnificent success by hydropathists, the production of pustules by means of croton oil or other irritant. He so marked associated pus with "sepsis" that the modern medical man looks on pus as an utter abomination under any circumstances. A seton will set up an active discharge of pus, even if put in with every

aseptic precaution and covered with sterile dressings. There are many significant statements in Dr. Gougerot's article. For instance: (1) "I think, too, that in all probability the skin not only fixes the toxins, but burns them up." Dr. Gougerot mentions the skin only, but what about the subcutaneous tissue? There are millions of people alive to-day who owe their continued existence here to the fact that the subcutaneous tissue is capable of accommodating and fixing an enormous amount of toxic material.

There surely are few medical men who have not seen the enormous relief to patients that follows the free scarification of oedematous legs and other parts. Most of them look on it as largely mechanical, but to my mind the relief is due to extrusion of germs and toxins through the slits in the skin.

(2) "If the activity of the skin be artificially stimulated by mustard baths or what not, the cutaneous defence again comes into action, as shown by the appearance of the eruption, the poisons are burnt up, and the disease assumes a less grave aspect."

Here Dr. Gougerot shows the timidity that so largely characterises leaders of thought in medical circles. He merely mentions mustard. Why not croton oil or cantharides when the lives of valuable, sorely-needed men are at stake? The risk is infinitesimal if these grand drugs are skilfully used, the possibility of cure as the result of employing them is great. I never hesitate to use them freely myself in any condition, from broncho-pneumonia in an infant to arthritis deformans in an aged patient.

(3) "Each pink spot is due to a small microbial embolus of living or dead microbes, *conveyed thither by the blood.*" Here is a bold statement of the fact that the blood is able to carry germs and toxins to the skin. In other words it actively sets to work to remove germs and toxins from vital organs to the skin, or, as I prefer to put it, the skin and subcutaneous tissues.

There is one paragraph in the article which is not very clear to me, and I should be grateful to you, Sir, or any of your readers, for enlightenment.

"Defective resistance on the part of the organism is the principal cause of the ill-defined or 'gone in' eruptions, but it seems possible that other causes may hinder the cutaneous reaction, as, for instance, the existence of a visceral inflammation (inflammation of the lungs, for example), thus preventing destruction of poisons in the skin and rendering the disease *pro tanto* graver."

I should very much like to comment still further on this valuable article, and give examples of the really excellent and gratifying results I have obtained by setting up reactions in the skin and subcutaneous tissues by means of croton oil and cantharides, but I am afraid my letter is already too long. I therefore merely ask leave to point to articles I have published. (a).

I am, Sir, yours truly,

W. J. MIDELTON.

112 Charminster Road,
Bournemouth.

June 9th, 1916.

THE MEDICAL DEFENCE UNION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Let me remind Dr. Dennis Vinrace of the saying of Eurypides that "Silence is an answer to a wise man." As he refers to our correspondence during September and October, 1915, I may point out

(a) *Lancet*, 1907; *Practitioner*, January, 1912; *MEDICAL PRESS AND CIRCULAR*, May 8th, 1912, and October 15th, 1913; *British Medical Journal*, 1913.

that in a letter which I wrote, and which appeared in your columns on September 22nd, 1915, I concluded with the statement, "I shall not trouble you with further correspondence on this subject." There the matter ended so far as I am concerned, and I have not the least intention of taking it up again.

I am, Sir, yours truly,

S. J. ROSS.

Monkhams, Bedford.

June 7th, 1916.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, MARCH 31, 1916.

The President, E. J. McWEENEY, M.D.,
F.R.C.P.I., in the Chair.

REMARKS ON THE VALUE OF CHINA GREEN FOR THE ISOLATION OF TYPHOID BACILLI FROM THE FÆCES.

A paper on this subject was read by the President, who began by referring to the increased importance of the search for typhoid bacilli in fæces not so much for diagnostic purpose as with the object of discovering bacillus carriers, whose presence was a source of danger. An American worker, Churchman, had ascertained the curious fact that the addition of gentian violet to nutrient agar in the proportion of about 1:100,000 had, roughly speaking, the effect of stopping the growth of Gram-positive organisms, whilst the Gram-negative species developed. Krumwiede and Pratt found that several green colouring matters in certain concentrations checked the growth of coli while permitting that of typhoid. Browning, Gilmore, and Mackie found that brilliant green in peptone water powerfully suppressed the growth of coli whilst that of typhoid took place. So far back as 1909, he (the speaker) had commenced experimenting with China green, and had obtained favourable results, which he had laid before the British Medical Association at Belfast. He now reported the results of further experiments. The dye must be used in two ways, first as an addition to agar for direct plating, and secondly, added to broth or peptone water as a preliminary enrichment medium before plating out. He had found that the addition of about 3.5 c.c. of 1/1,000 solution per 100 c.c. 3 per cent. agar kept back the growth of most of the coli, whilst it allowed typhoid to grow. The stain, however, showed a tendency to inhibit the growth of typhoid whilst encouraging that of the para-typhoid group. The preliminary culture in peptone water containing 0.3 c.c. of a 1/1,000 solution also tended to depress the coli whilst allowing typhoid to grow. But so far he had not succeeded in obtaining results so satisfactory as those recorded by Browning with brilliant green. In his (the speaker's) opinion much depended on the amount of organic matter present. When the bacilli were added in a medium rich in organic matter (such as fæces) the dye exercised a much less depressing influence on microbial growth generally than when they were added in broth cultures. It was not always easy to form correct conclusions at once as to the typhoidal nature of the colonies appearing on plates containing the colouring matter, as colonies that at first resembled typhoid proved subsequently not to be of that nature. Sub-

cultures to restore motility, sugar and serum tests had to be made. Although he had not yet succeeded in obtaining perfectly satisfactory results from the use of China green, either in plates or as an enrichment method, he thought the outlook sufficiently favourable to justify him in continuing his work on the subject.

Dr. R. J. ROWLETTE said that prior to the war, Widal's reaction was regarded as the reliable diagnostic test, but with the introduction of inoculation the examination of the faeces has become much more important. He asked, was China green a suitable medium for the examination of the urine?

Dr. W. D. O'KELLY said his objection to the China green method with solid media was that there was not a sharp enough contrast between typhoid and coli colonies. He considered the green dyes were useful in enriching the typhoid in fluid media when subsequent subcultures on a differentiating medium like Endo was used. He also considered that the individual typhoid strains differed, often markedly, in their action with the same dye; this was noticeable in the marked favouritism of China green to the paratyphoid bacilli. He had met one strain of typhoid which seemed to assume lactose fermenting properties although subcultured from an originally genuine non-lactose fermenting colony.

Dr. T. T. O'FARRELL said he had recently cause to realise the importance of a good method for examination of faeces, as he had found high agglutinating power against *B. typhosus*, *B. paratyphosus A.* and *B.* in the sera of soldiers who had received the mixed vaccine.

Dr. W. BOXWELL favoured the treatment of comparatively large volumes of faeces with brilliant green with subsequent plating on Conradi-Drigalski medium. He asked, was China green of any use for the isolation of dysentery bacilli?

The PRESIDENT, in reply, stated with regard to urinary cases he centrifuged the specimen, and plated the sediment upon Conradi-Drigalski medium. The cultures were often obtained quite pure, so that plain agar was often sufficient without differentiating media. He considered blood culture was of primary importance in all suspected cases of typhoid. He had no experience of China green with dysentery, but Krumwiede and Pratt had found it to be inhibited quite as much as *B. coli*, so that it would not be a suitable medium.

ABDOMINAL TUMOUR.

Drs. R. J. ROWLETTE and W. BOXWELL showed the abdominal viscera from a woman aged 62. She had noticed her abdomen enlarging for three months, but had no pain nor wasting; for three weeks prior to her death she had vomiting and diarrhoea. The viscera showed the omentum occupied by a tumour-mass infiltrating it in every part; it also infiltrated the mesentery and the peritoneum, covering the right lobe of the diaphragm, and there were small implantations elsewhere on the parietal peritoneum. No primary seat of carcinoma could be discovered. There were no secondary deposits elsewhere in the body. *Microscopically* the tumour was found to consist of large flat cells, varying greatly in appearance. Some appeared to be actively phagocytic; in many the nucleus was in process of division; no mitotic figures were seen. There were many giant cells similar to those seen in giant-cell sarcoma, and there were many multinuclear protoplasmic masses resembling syncytial masses. Cell-inclusions were present. The stroma was scanty; lymph spaces were well marked. Much of the tissue of the tumour was necrotic. Where the tumour was in contact with muscle tissue, as on the intestinal

wall and the diaphragm, the tumour cells could be seen infiltrating between the muscle bundles. The exhibitors regarded the tumour as an endothelioma originating in her peritoneum.

The PRESIDENT said the case closely resembled the description of endothelioma peritonei given by Aschoff; he considered the nodular appearance, superficial distribution, and the absence of cachexia as characteristic. He had seen a case of the condition in the omentum which formed a belt across the abdominal viscera and superficially had the appearance of a large cancer of the transverse colon, but it had no connection with the lumen of the bowel, and microscopically it was an endothelioma.

Dr. W. D. O'KELLY said he had met primary endothelioma of the ovary with secondary invasion of the peritoneum. To the naked eye the ovary appeared normal, though microscopically endothelioma was readily demonstrable.

Dr. J. H. POLLOCK regarded the giant cells as being in the nature of foreign body giant cells.

Dr. R. J. ROWLETTE said the ovaries appeared normal to the naked eye. He had met a case of primary endothelioma of the ovary with metastases in the peritoneum, but the appearance had no resemblance to that of the specimen shown.

SYPHILITIC SPECIMENS.

Dr. J. H. POLLOCK demonstrated a specimen of syphilitic liver obtained from an infant of eleven months old, who succumbed to an apparently primary hepatitis. Cellular infiltration of a diffuse nature, together with gummatous formations, were present. The histology was typical, and spirochaetes were demonstrable by Levaditi's method. He thought it was possibly unusual to see a liver in this precise condition, as such cases usually either died during intra-uterine life or survived sufficiently long for fibrotic changes to occur.

He also showed a specimen of testicular gumma and a preparation of spleen from a macerated foetus, exhibiting *Spirochaete pallida* in extreme numbers.

SPECIMEN FROM A CASE OF PARATYPHOID (?).

Dr. G. E. NESBITT showed the kidneys and portion of small intestine from a case with puzzling clinical symptoms. The patient, a girl of 15, was admitted to hospital as suffering from nephritis, the urine containing 0.4 per cent. of albumin, and half the normal output of urea. The arteries were distinctly hardened, the aortic second sound accentuated and the blood pressure raised. She complained of occasional abdominal pain, for which no satisfactory explanation was apparent. She had no fever. On the tenth day after admission, she had a sudden large hæmorrhage from the bowel. The abdominal pain became acute, and she vomited frequently. As these symptoms persisted for two days without improvement laparotomy was performed. The abdomen was found to be normal, with the exception of the lower end of the ileum, which was studded with hæmorrhagic areas running for the most part in a transverse direction. The appearance was somewhat suggestive of typhoid, and the same day the blood was examined, with a positive reaction, for *B. paratyphosus A.* in dilution 1:80. Two days later the child died. A limited autopsy was performed. The abdomen contained pus, due to two small perforations. The lower end of the ileum showed numerous small circular ulcers of various depths. Peyer's patches were not affected, nor were the mesenteric glands or spleen enlarged. The colon and cæcum were free. The left kidney was large and granular, with large adherent

capsule. The right was congenitally small, about the size of a walnut. The clinical history and pathological findings seemed to be opposed to a diagnosis of paratyphoid, but in the absence of complete bacteriological investigation no definite opinion could be expressed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JUNE 2ND, 1916.

The President, DR. LEONARD DOBSON, in the Chair.

DR. J. DUNDAS GRANT read a paper on SOME POINTS OF PRACTICAL INTEREST IN THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE NOSE, THROAT AND EAR.

Beginning with the subject of nasal affections, the author said that a nasal discharge was sometimes simply due to eczema of the nasal vestibule, owing, in part, to too zealous irrigation with saline solutions. This could be cured by the cessation of irrigation, and by the use of a simple ointment. In acute nasal catarrh the sinuses were frequently involved, and various remedies were suggested. In asthma the condition of the nares should always be examined. For ozæna a very efficient method of cleansing the nose with an alkaline solution was demonstrated. Other methods of treatment were described. One form of nasal obstruction often overlooked was due to collapse of the *alæ nasi*. As regards throat affections, the fact that persistent hoarseness might be due to carcinoma of the larynx, necessitating immediate operation, was frequently overlooked; whereas pharyngo-mycosis, which generally disappeared spontaneously after some period, shorter or longer, caused early alarm. After discussing the various causes of stridor, dysphagia, regurgitation of food, and hæmorrhage from the mouth, Dr. Dundas Grant passed on to the consideration of vertigo and relaxation of the *membrana tympani*, and concluded by demonstrating an ingenious method of detecting simulated deafness.

The following skiagrams were shown by Dr. STANLEY MELVILLE:—(1) Cardio-spasm; (2) rabbit-bone (vertebra) in right bronchus (removed by operation); (3) safety-pin in right bronchus (removed by operation); (4) spasm of upper part of œsophagus; (5) irregular left frontal sinus.

OBITUARY.

DR. DUNCAN MENZIES, M.A., M.B., C.M., LONDON.

WE regret to announce the death, on May 28th, of Dr. Duncan Menzies, of Dorset Square, after a motor accident. Dr. Menzies was a native of Perthshire. He studied at Edinburgh University, graduating M.B., C.M., in 1883. Shortly afterwards he came to London, and settled in Marylebone, where he built up a large practice. Dr. Menzies was a sound physician and a straightforward Scotsman. His qualities endeared him to a large circle of friends and patients, by whom he will be sadly missed. He leaves a widow, four sons and one daughter. His eldest son, Dr. James Menzies, holds a commission in the R.A.M.C., and is at present at Salonica. His other three sons are also in the army.

DR. A. E. PALMER, M.R.C.S., L.R.C.P., LOUGHBOROUGH.

THE death took place at Mundesley, Norfolk, on June 4th, of Dr. Arthur Ernest Palmer, aged 49, of Loughborough. The deceased, who was a bachelor,

had been ailing for some time from an affection of the throat. He was the second son of Dr. Grimes Palmer, and brother of the late Dr. W. G. Palmer, claiming association with one of the oldest-established medical practices in the district. Educated at the local Grammar School, he proceeded to Guy's Hospital, London, qualifying M.R.C.S., L.R.C.P. in 1889. A subsequent appointment as House Surgeon to the Torquay Hospital preceded his election as House Surgeon at the Loughborough Hospital, where he built up a reputation as an anæsthetist. In 1898 he joined Dr. J. B. Pike in private practice, and was in partnership till his death.

DR. HUGH MACNAUGHT, M.B., CH.B., GATESHEAD.

ON June 3rd, Dr. Hugh MacNaught died suddenly at Gateshead. The deceased gentleman, who was about 32 years of age, came to Gateshead from Glasgow in 1912. He qualified M.B., Ch.B., at Glasgow in 1908.

REVIEWS OF BOOKS.

SURGICAL ANÆSTHESIA. (a)

THE author has considerably improved the appearance of the second edition of his book by increasing the size of the page, and he has thus been able to add some new matter without increasing the number of pages. The key-note of Mr. Gardner's teaching in the previous edition of his work was the necessity of avoiding all trace of asphyxia, or, as he calls it, "anoxæmia" during anaesthesia, and this teaching is insisted on as vigorously as before in the new edition. There can be no doubt that the matter is of the first importance to the anæsthetist, and the author is to be congratulated for his insistence on it. The chief additions now made to the work are a short chapter on anoci-association, and one on intratracheal insufflation anaesthesia. These important subjects are treated in a very brief way, and the student is given little help in deciding how far the methods should be adopted. After a careful study of the book, one is at a loss to know whether the author recommends them or not.

The introductory chapter on the History of Surgical Anaesthesia is almost word for word as it was in the edition of 1909. In the *British Medical Journal* for April 13th, 1912, there was communicated from the Wellcome Historical Medical Exhibition Research a paper describing the life and work of Henry Hill Hickman, a forgotten pioneer of surgical anaesthesia. Hickman's work on carbon dioxide and nitrous oxide gases, published between 1820 and his death, at the age of 29, in 1829, is perhaps the most remarkable work on anaesthesia that preceded the discovery of Wells and Morton. We are surprised not to find Hickman's name or work referred to in Mr. Gardner's book.

We regret to find a good deal of careless writing, since by it the author's meaning is rendered obscure and the reader's attention is distracted from the subject. We take two instances, both of which occur on the same page. "The safest method is to warm the table and bed with bottles before the patient is laid upon them, and then remove them, but to trust entirely to warm blankets during operation, and afterwards in bed, until complete consciousness and sensation are restored." "In the case of nitrous oxide, which is commonly administered in the day clothing, care must be taken that females actually unloosen their corsets, for the author has seen hesitating, irregular breathing, and in two instances complete respiratory cessation, due entirely to tight corsets."

The author adopts a curious plan, and one that we cannot commend, with regard to his references. He refers to the third edition of Dr. Dudley Buxton's work, published in 1900, though he might equally well

(a) "A Manual of Surgical Anaesthesia." By Bellamy Gardner, M.R.C.S. Eng., L.R.C.P. Lond., Honorary Anæsthetist to the King George Hospital. 8vo, pp. 232. Second edition. London: Baillière, Tindall and Cox. 1916. Price 7s. 6d.

have referred to the fifth edition, published in 1914. In some places he refers to the third edition of Sir Frederick Hewitt's book published in 1907, and in another place to the fifth edition, though the last edition was the fourth, published in 1912. These are instances of carelessness which considerably mar the book, and make one hesitate to recommend its use even though it contains valuable teaching.

THE "MEDICAL ANNUAL" AND THE SYNOPTICAL INDEX. (a)

THE doctor's spring is not complete until he has received his *Medical Annual*, and it is with pleasure we congratulate the anonymous editor on the high standard of the present volume. He has taken full use of his opportunities to gather together the results of the special investigations which the war has made necessary. There have been many advances in military medicine and surgery, and this book gives an excellent summary of them. No medical officer in His Majesty's Forces can take a more useful text-book in his kit than the *Medical Annual*. Notwithstanding the special attention given to military subjects, the general practitioner still finds the *Annual* a treasure-house of inspirations for his practice. He who reads it carefully may be satisfied that he is keeping abreast with the progress of knowledge.

Dr. Herbert French again writes the articles on General Medicine; Major De Courcy Wheeler, a new contributor, has charge of General Surgery; and Dr. Bryden Glending again writes on Gynecology and Obstetrics. We note with pleasure that Major Wheeler supports Mr. Robert Jones in his condemnation of operative treatment of septic fractures. Dr. Robert Hutchison makes the incautious statement, following Barrett and Smith, that "pyorrhœa alveolaris is caused by a specific amoeba—the *Entamoeba buccalis*." It is true that an amoeba is to be found in the pockets in pyorrhœa, as in most other septic conditions of the mouth, but no causal relation has been proved. The results of treatment based on the hypothesis of a causal relation are not at all as good as those given by vaccine treatment. The subject of vaccines receives two articles—one of two pages in the General Review of Therapeutics by Dr. F. J. Charteris, and one of two-thirds of a page by Dr. Grüner. The latter is very inadequate, and contains a curious, if unconvincing, suggestion to explain the superiority of autogenous over stock vaccines. Dr. E. W. Goodall writes a useful article on Cerebro-Spinal Fever, but he gives insufficient information on the bacteriology of the disease, a subject on which much has been written in the last year or two. Dr. Herbert French recounts some of the many new methods of treating exophthalmic goitre, none of which seem to stand the test. We are grateful to Dr. Bedford Pierce for a judicious article on Psycho-analysis. It seemed for long that the solid truths which underlie psycho-analytic doctrine were likely to be overlooked because of the prejudices aroused by the fanciful superstructure. The doctrine deserves more study than it has yet received in England.

The editor reprints the unhelpful and irritating two-page glossary from last year's issue. The definition of "antiformin" is insufficient and ungrammatical. This glossary should be dropped in future issues or made adequate. One other suggestion we make—that the names of authors quoted in the text should be given in an index, general or special.

We also welcome a new volume of the *Medical Annual Synoptical Index* which covers the ten years 1905 to 1914. To the wise man who keeps his volumes of the *Medical Annual* on a convenient shelf, the *Index* saves much labour. The entries appear under the headings of the various diseases and methods of treatment, and the inquirer can find in a moment the references he wants in the ten volumes covered by the index. It is, indeed, an interesting

and suggestive exercise to follow any particular subject through its several references.

A NEW TREATMENT FOR GONORRHŒA. (a)

WE have read this little book with interest and profit, and cordially recommend it to the profession. Dr. Russ, while confident that gonorrhœa is a disease which can be cured, is not enthusiastic over present methods of treatment. Undoubtedly he is right in pointing out that the unsatisfactory results not uncommon are largely to be attributed to the fact that in the majority of cases the treatment prescribed is left to be carried out (*i.e.*, the manipulations of injections, etc.) by the patients themselves. We would add that a huge stumbling-block to the surgeon is the impossibility, in many cases, of getting the patient to abstain from alcohol. In our opinion the importance of this factor cannot be overestimated.

After a critical survey of the methods most commonly employed to combat gonococcal infection—*viz.*, internal administration of urinary antiseptics, injection, irrigation, and the use of vaccines, Dr. Russ describes the system of treatment by electrolysis, evolved by himself. "It is founded upon the experimental studies of the behaviour of bacteria immersed in fluids which are traversed by a constant electric current, and the observations apply to the gonococcus as well as to other bacteria." By means of a simple apparatus clearly described, and the use of a 2 per cent. solution of sodium iodide, he has had most favourable results. After a treatment of over 70 cases, he states the advantages of the electrolytic method to be (1) limitation of inflammation to the anterior urethra; (2) absence or rarity of arthritis, ophthalmia, and epididymitis; (3) comparative rapidity of cure; (4) procedure is painless. He maintains that cure is obtained in from ten to twenty-two treatments.

The only adverse criticism of Dr. Russ's methods we have heard is the suggestion that stricture may follow. Only time, of course, can elucidate this, but with the weak current used, and if the cure be rapid, no deep ulceration can have been present, so we do not emphasise such possibility.

With the probability, almost certainty, of a large increase in the incidence of gonorrhœa within the next few years, and in view of the recommendations of the Commission on Venereal Diseases, we welcome this small work as pointing to a distinct advance in our efforts to master a disease, so often belittled, but which may have most dire results.

INFECTIOUS DISEASES. (b)

THE kernel of this book is to be found on the surface—that is, in the first two chapters, and the purpose and scope of the book are printed on the yellow wrapper which enfolds it. We have here a series of lectures on dietetics, somewhat novel both in subject and treatment, but, to quote the wrapper, "thoroughly practical." Dr. Meara "instructs rather than discusses."

Two or three physiological principles are first stated—one that the average man, when in a state of complete rest, requires food having a heat value of 3,000 large calories per diem; another, that the sick man at rest, especially the man stricken with an infective fever, requires not only as much food, but more than the healthy man. Lastly, we are taught that the idea of high fever impairing digestive functions is a myth, and the necessity for a spare and purely liquid diet for a typhoid patient an ignorant superstition.

Graves' classic epitaph "He fed fevers" is here carried out literally and with a vengeance. Dr. Meara, to be sure, deprecates stuffing his patients like barnyard fowls, but he gives as a model daily dietary a menu sheet that at first sight suggests enough food to last an ordinary man for days. In this country we are not accustomed to measuring food in terms of

(b) "The Treatment of Acute Infectious Diseases." By Frank Shearman Meara, M.D., Ph.D. The Macmillan Co., N.Y. Pp. 540. Price 15s.

grams or calories—or, indeed, to measuring the quantities of food given, as a routine practice, at all. Perhaps, if we did, the amount urged by Dr. Meara might not appear so formidable. But his treatment does not end with giving food. Drugs, serum, vaccines and hydrotherapy are not forgotten, and here we must mention one admirable quality throughout the work—detail. It is not sufficient to know that your patient must go to bed. You must know all about the bed and how to make it, and make it comfortable for the patient and convenient for the nurse. We are re-introduced, too, to the cold tub, and the "slush" (not a mud-bath, by the way) instead of tepid sponging, and to open-air treatment. To the uninitiated the latter term might seem a misnomer, seeing that the patient is hermetically sealed in an air- and water-tight envelope up to his chin, his head muffled in a hood, to say nothing of a barricade of hot bottles, pillows and screens to shield him from the wind. The benefit is apparently derived not so much from the breathing of fresh air, as from the vaso-motor stimulation aroused by the exposure of the patient's face and upper air passages to the cold.

While chicken-pox has a chapter to itself among the thirty-five infections dealt with, the pneumonias and acute bronchitis are all taken together, and in general treated alike. To us lobar pneumonia, or pneumonic fever, is something quite *sui generis*—an inexplicable, self-limited mystery, unlike anything else in medicine, and, one would suppose, calling for a distinct line of treatment. We have always regarded over-feeding as a very real danger in this disease, a danger of which our nurses require warning, not encouragement in the opposite direction.

A special feature of the work is the recapitulation of the subject matter of each several chapter in tabular form, a process which only accentuates the many verbatim repetitions in the text, and adds unnecessary bulk to a rather heavy book. On the whole, however, Dr. Meara's book is a valuable addition to our dictionaries of treatment, and his methods are an object lesson in plain speaking and practical thoroughness.

Yet, one is tempted to ask, is there so much difference in the death-rate, for instance, of typhoid fever, when we compare his vigorous methods with our own?

TROPICAL MEDICINE OF ELIZABETHAN TIMES. (a)

How to preserve the health of those who go down to the sea in ships has long been a problem of great interest, and especially to Englishmen since the reign of Queen Elizabeth. In bygone days the perils of the sea were, one would have thought, sufficient to daunt the bravest, but those perils were small compared with the perils of disease to which every sailor on a long voyage was exposed. Scurvy in particular not infrequently caused fearful havoc among a ship's crew. Though now the disease is rarely seen, yet in the past many books have been written to explain its cause, its prevention, and its cure. Dr. Singer has presented us with an admirable facsimile reproduction of the earliest of such works, devoted to naval or tropical medicine, published in the English tongue. The book was written by one "G. W.," whom Dr. Singer identifies with the Elizabethan poet and gallant, George Whetstone. Whetstone was born about 1544. He fought the Spaniards in the Low Countries, he published plays in London, he attempted a voyage to Newfoundland, and he travelled in Italy. His "Cures of the Diseased, in Remote Regions" was not looked on as an important contribution to medicine even at the time it was first published, but there is no question as to its interest to those of us who are interested in the history of medicine. In the treatment of scurvy, Whetstone tells us that "it is a certain and assured medicine against this Disease, to haue such quantitie of Beere brewed with Graynes and

Long pepper, as in the morning twice euerie weeke there may be giue a good draught to a man, proportioning three quarters of a pound of Graines, and three quarters of a pound of Pepper to a hogshead of Beere." It is interesting to note that David MacBride, writing from Dublin in 1767, recommends for the prevention and treatment of scurvy "fresh wort, or infusion of malt," as "a liquor similar to the recent juices of the sweet vegetables; fermenting regularly like them, and being precisely of the same mild, saponaceous, and aperient nature."

Dr. Singer has placed the profession in his debt by his many researches in the history of medicine, and he has made a notable addition to this debt by the publication of this rare little tract that now lies before us. The tract is printed with the well-known taste and care of the Clarendon Press.

WEIR MITCHELL. (a)

On January 4th, 1914, the world was left the poorer by the passing from it of Silas Weir Mitchell. For more than half a century he had been giving to the world with both hands of the fullness of his knowledge and his work, yet the supply seemed to be inexhaustible. Suddenly the fountain ran dry, and we were almost numbed by the shock. Gradually, however, as we recover from the shock, we are beginning to appreciate the vast fruitfulness that has come from that fountain, and that though the source is gone the beneficent influence will long remain. It is right and fitting that the memory of such a man as Weir Mitchell should be kept green amongst us. Not only is it due to the man as a tribute to his merit, but also it is due to those that follow us that they, too, may share the benefits that he has conferred on us.

Mitchell's activities were manifold. In medicine, in prose writing, and in poetry he excelled; he was a stimulating and encouraging teacher, a research worker who brought many new facts to light, and a wise and temperate social reformer. No wonder America is proud of her great son at whose feet each nation of the world was glad to lay its tribute.

Just as a great man who belongs to his country, belongs in a more particular way to his family, so Weir Mitchell belongs particularly to the College of Physicians of Philadelphia. To Mitchell his College was especially dear. Apart from the lustre which his fame has shed upon it, he has benefited it by his wise counsel and sympathy, and enriched it with his princely gifts. Pictures, books, and manuscripts, nothing was too good or too costly for his College. In this, too, his example stimulated others.

The College has not been unmindful of the debt she owes, and the handsome volume before us will help posterity to appreciate Mitchell's worth. It was a happy inspiration to hold the memorial meeting of which this volume is a record in the hall of the College of Physicians of Philadelphia, where every stone was a monument to him. The gods have little left to give to one who merited the tributes there spoken and here printed, tributes to the man, to the man of science, and to the man of letters.

LABORATORY NOTES.

"SOLOID" NASAL ALKALINE COMPOUND.
(BURROUGHS, WELLCOME AND CO., SNOW
HILL BUILDINGS, LONDON, E.C.)

WE have received a sample of this useful product, which has been modified by the addition of cocaine hydrochloride. This enables a spray or douche to be applied with advantage in the treatment of acute painful affections of the nasal passages. Each product contains 5 grains of borax, 5 grains of sodium chloride, and 1-6th grain of cocaine hydrochloride, and dissolves readily when powdered in warm water. One dissolved in two or three ounces of water yields an antiseptic fluid for use as a spray or douche in rhinitis and other nasal and naso-pharyngeal diseases. The original soloid without cocaine hydrochloride is still supplied.

(a) "S. Weir Mitchell, M.D., LL.D., F.R.S., 1829-1914. Memorial Addresses and Resolutions." Philadelphia, 1914. 8vo., pp. 155. Portrait. Philadelphia: Taylor and Co.

MEDICAL NEWS IN BRIEF.

Torquay's Health.

DR. T. DUNLOP, the Medical Officer of Health for Torquay, has prepared his annual report. In reference to the population, he states that according to the 1911 census, the females numbered 21,738 and males 17,933.

The total births registered during the year was 490—males 255, females 235; being 52 less than in 1914. Of the 490 births, 39 were illegitimate, compared with 35 last year. The birth-rate of 12.4 per 1,000, as compared with 21.9 for England and Wales, was by far the lowest rate recorded. The question, however, might be raised, why should the Torquay rate be so much lower than that of the country as a whole. The answer was that in making such comparisons they must bear in mind the constitution of the population. In Torquay they had a large excess of females over males, a large proportion of the females were spinsters, and some 40 per cent. were either above or below the child-bearing age. In the face of such facts, it was unreasonable to expect anything but a low birth-rate. Such a decrease was indeed disquieting, even in times of peace, but under present circumstances, when the war was taking such a toll of human life, it was essential that the Government and sanitary authorities should utilise every means to preserve the lives of those children born.

The return with respect to vaccination showed that of 572 births registered, 217 were successfully vaccinated. There were 301 certificates of exemption granted to conscientious objectors. The Medical Officer remarked: "In my last report I pointed out that 1913 was the first year on record in which the number of conscientious exemptions exceeds the number of children successfully vaccinated. The figures for 1914 show a similar condition of things, except that the difference is greater. In a few years the system of vaccination will be a dead letter. This yearly increase in the number of persons unprotected from small-pox undoubtedly means that if this dread disease should be introduced, a severe and costly epidemic will result."

The total deaths registered in the borough during 1915 was 543. The net deaths belonging to Torquay were 576, males 262, females 314. This was an increase of 88 over those registered in 1914.

There were 41 deaths of children under one year of age, against 45 in 1914. As there were 490 births registered, the infantile mortality was 83.6 per 1,000 births. The rate for England and Wales in 1915 was 110.

Popular Scarborough Doctor.

AN interesting event took place at Scarborough at the weekly practice of the local division of the St. John Ambulance Association on May 28th, when each member present was formally presented by the Earl of Londesborough with a cabinet-sized photograph of their late surgeon and founder, Dr. C. A. Wilkinson.

The Earl, in making the presentation, said that in the death of Dr. Wilkinson he had lost not only a great personal friend, but one who had always been of much help to him on the joint-committee of the St. John and Red Cross in Scarborough, which had not been in formation for any length of time, and as a member of the British Red Cross Society.

Compliment to a Portrush Medical Man.

IN recognition of their services on a night in February last, when the local lifeboat was called out to the aid of a minesweeper in difficulties off the Antrim coast, Dr. Wm. Porter and Mr. J. G. McMorris (manager of the Belfast Bank) were presented with appropriate souvenirs by the Royal National Lifeboat Institution.

On the occasion some members of the crew refused to go out with the boat on account of the tempestuous

sea which raged at the time. Dr. Porter and Mr. McMorris motored to Portstewart, where they secured sufficient volunteers to complete the crew, and the lifeboat then set out to the assistance of the distressed vessel. Dr. Porter gallantly went out in the lifeboat in the hope of being able to render aid to the members of the crew of the minesweeper.

The presentations were made at a meeting of the local committee of the National Lifeboat Institution, in the Belfast Bank.

The award to Dr. Porter was a framed vellum certificate, which states:—"At a meeting of the committee of management of the Royal National Lifeboat Institution for the Preservation of Life from Shipwreck, held at their Offices, London, on the 14th April, 1916, the following minute was ordered to be recorded on the books of the Society: 'That the best thanks of the Royal National Lifeboat Institution be accorded to Wm. Porter, Esq., M.D. (Portrush), in recognition of his persistent efforts to obtain a crew to man the Portrush Lifeboat when called for service to H.M. minesweeper Grateful, in a north-west gale and very heavy sea, on the night of the 25th February, 1916, and of the stimulus given by his example in going out in the boat as a volunteer.'

Royal Medical Benevolent Fund of Ireland.

THE annual meeting of the Royal Medical Benevolent Fund of Ireland, was held in the Royal College of Surgeons, on June 7th, Mr. William Taylor, Vice-President of the College, presiding.

The report stated that the total number of applications considered during the year was 93. Of these 84 were from widows of medical men, three from, or on behalf of, their orphans, and three from medical men themselves. The total amount of grants during the year was £1,232 13s. 6d.

Southend Naval Hospital.

TEN thousand people brought gifts of money and provisions to Queen Mary's Naval Hospital at Southend on June 7th. The Queen herself sent a cheque for £100, a case of walking-sticks, and other things. The gifts were formally received by the Duchess of Portland.

Birmingham Hospital Unit.

THE hospital unit organised in Birmingham some time ago for service with the British Army left for Aldershot on June 5th, where it had been ordered to mobilise.

Most of the members of the unit are men who have practices in Birmingham and the immediate neighbourhood. A few are from outside the city, but nearly all of these have been associated with the Birmingham School of Medicine either as doctors or as students. Dr. Leonard Parsons, assistant physician at the Birmingham General Hospital, goes as principal officer on the medical side, and Mr. Percival Mills, surgeon to the Royal Orthopaedic and Spinal Hospital and assistant surgeon to the General Hospital, and Mr. J. H. Watson, hon. surgeon, Victoria Infirmary, Burnley, and formerly demonstrator of anatomy at the Birmingham School of Medicine, will have charge of the surgical side. The pathologist is Dr. J. Graham Forbes, bacteriologist, Hospital for Sick Children, Great Ormond Street, and divisional medical officer under the London County Council; and the radiographer is Dr. A. E. Carver, radiographer to the Hospital for Nervous Diseases, Birmingham, and tuberculosis officer at the Birmingham General Dispensary.

Women Nurses in Asylums.

COMMENTING, in his annual report, on the introduction of female nursing to male wards at certain lunatic asylums owing to the difficulty of getting male attendants, Dr. Passmore, medical superintendent of Croydon Mental Hospital, says:—"To my mind the work is degrading to refined women. I have had the opportunity of conversing with some of those who have been thus employed. I find that they deprecate the system in the strongest possible way."

The London Hospital.

At the quarterly Court of Governors of the London Hospital, on June 7th, the House Committee reported that, owing to the continuance of the war, the running of the hospital had been more difficult than ever. The financial position was such as to cause the Committee some anxious thought last year; and as a consequence of the great rise in the cost of all articles of food as well as of drugs, dressings, and everything used in that institution, it was feared that at the end of the year things would be worse. A sub-committee had been formed to go into the details of the working of the hospital. It had always been the aim of the Committee to prevent as far as possible any hardship falling on the civilian sick on account of the war. Several hospitals had closed their out-patient departments altogether, but it was hoped that it would not be found necessary to close any portion of the out-patient department at the London Hospital. They would, however, shortly be working there in circumstances so unusual that it was hard to say what might occur. For instance, the great majority of the clerks would have left by the end of July, and their places would be filled by ladies. Valuable as their work might be, some of it was so technical that it took a very considerable time for it to be learned. Similarly, some of their dispensers were being called up, and their places were being filled by lady dispensers. The St. Anthony Wards, generously presented by the Grocers' Company, had been opened, and they had already treated with conspicuous success 156 patients suffering from venereal disease. Mr. Walter Long, the President of the Local Government Board, accompanied by Dr. Newsholme, the Chief Medical Officer of the Board, had visited the wards, and expressed himself as most pleased with the work they were doing. Two of the present sisters had received the distinction of being decorated with the 2nd Class Royal Red Cross, and seven other former London nurses had received the same distinction in the King's Birthday Honours List.

Mr. Douro Hoare (the Chairman), in moving the adoption of the report, referred to the great loss which the country had sustained by the death of Lord Kitchener, and Mr. E. W. Morris (the Secretary) mentioned that when they received the first batch of wounded at the hospital Lord Kitchener came down at once and saw every one of the patients personally.

Liverpool Eye and Ear Infirmary.

At the annual meeting of the above Institution, on June 7th, it was stated that 7,860 new eye cases and 3,304 new ear cases were reported in the out-patients' department, and the attendances these involved numbered 27,368. The in-patients occupying beds during the year had been 827.

In their report the Committee stated that, as last year, they considered it inadvisable to continue their appeal for funds to free the hospital from debt and for altering and equipping the proposed new building, and, in consequence, the amount received on this account showed a marked decrease. This year the Committee had been able to place all legacies received to a special account to form the nucleus of a reserve fund to meet extraordinary expenditure in future. Legacies to the amount of £1,673 had been received and placed to this special account. There was a slight decrease in the amount of the subscriptions for the year, but the Committee had cause to be pleased that this decrease was no greater than it was when the call upon the public purse for war charities and the increase in wages and taxation were taken into consideration. The ward, containing sixteen beds, set apart for the treatment of wounded soldiers, had been fully occupied during the year, and many cases of wounds affecting the eyes, ears and head had been successfully treated by the medical staff.

Panel Doctor's Fines.

At a meeting of Falkirk Burgh Insurance Committee it was reported that in connection with the recent action of the committee in imposing a fine of £5 5s. on a local panel doctor for infringement of medical certification rules, a letter had been received

from the Scottish Insurance Commissioners stating that, having had the matter before them, they had decided to deduct the sum of £50 from the grant to be paid to the Insurance Committee, leaving it to them to deduct that sum from the payments to be made to the doctor. A letter was also read from the doctor in question protesting against the case again being taken up after he had already been tried and fined.—Mr. J. R. W. Ferguson moved that the matter be remitted back to the Medical Service Sub-Committee. He considered it a hardship to the doctor concerned that the Insurance Commissioners should take up the matter and inflict a heavier penalty than was thought necessary by the Medical Service Sub-Committee. If the Insurance Commissioners were going to override the decisions of the sub-committee, there was no need for that committee sitting at all.—Mr. Neil McLean seconded, and the motion was agreed to.

Massage Establishments.

By-laws for the regulation of establishments for massage or special treatment in London have been confirmed by the London County Council, so that the Council may be in a position to deal with objectionable features in connection with a number of such places which are regarded with suspicion.

City of London Tuberculosis Dispensary.

In his latest report the Medical Officer of Health for the City states that during March and April 355 persons, including 43 new patients, attended the City Tuberculosis Dispensary.

London Children's Health.

In the annual report of the London County Council school medical officer it is stated that during last year 308,959 children were examined in the schools, and of these 109,659 were found to require treatment. The results of the medical inspection of the selected age groups show a progressive improvement in the physical condition of the children. A total of 102,130 children were treated under the Council's medical treatment scheme, as compared with 86,819 in 1914.

Scarlet fever, which had manifested increasing prevalence since 1912, attained a maximum in 1914, and showed a decline in 1915. Diphtheria remained at practically the same level as in the preceding year. Measles was very prevalent during the early part of the year, and 31,313 cases were reported from schools. As in previous years, a large amount of work was done under the personal hygiene scheme, and satisfactory progress is recorded in connection with the institutional treatment of tuberculous children.

Nottingham Motor Ambulances.

On the appeal of Mr. Dennis Bayley, a representative meeting of lace manufacturers at Nottingham on June 7th decided to raise £3,000 to provide motor ambulances at the front. Mr. Bayley, who has now raised over £200 for this purpose, said that the ambulance convoy given by the Nottinghamshire and Derbyshire coal industry had been all through the Verdun battle, and was still there.

The Convalescents' Coach.

A coach and four is now making regular journeys between London and Laleham, about 40 miles out and home, for the benefit of wounded men from London hospitals. The trips have been started by Mr. T. W. Simpson, and the coach will ply three times a week throughout the summer.

The first trip was taken on June 5th from St. Thomas's Hospital with a party of 16 soldiers, including men who had fought at Mons, Ypres, Arras, Loos, and Hill 60.

Sanitation in War Time.

At a conference on sanitary administration under war conditions, held on June 9th, at the Royal Sanitary Institute, Mr. Percy H. Boulnois read a paper dealing in detail with the economies in municipal sanitary work considered

possible. Among the suggestions of Mr. Boulnois was that the keeping of dogs in large towns should be either prohibited or discouraged by a heavy tax. Dealing with the employment of women for street cleansing, he said they were inclined to be too particular, and to cleanse a street as if it were their own backyard, but so far as health was concerned that was a fault in the right direction. He mentioned a Chiswick experiment, in connection with street darkening, of fixing phosphorescent sulphide between sheets of glass on trees and turning off all the lamps. These luminous objects, however, proved too tempting as targets for boys, who broke them with stones.

It was announced that the Institute has offered a prize of £50 and a medal for the best thesis setting out a complete practical scheme for maternity and child welfare work suitable for adoption by local authorities.

Medical Council in the Field.

SIR ARTHUR SLOGGETT, Director-General of the Army Medical Services, in view of the difficulty which his principal officers experience in attending his Advisory Board meetings, has formed a kind of inner council consisting of members on whose presence he can always depend. He himself is chairman, and the vice-chairman is Surgeon-General T. B. Woodhouse, C.B. The members are Surgeon-General Sir G. H. Makins, K.C.M.G., C.B., F.R.C.S., Surgeon-General Sir A. A. Bowlby, K.C.M.G., K.C.V.O., F.R.C.S., Colonel Sir Wilmot Herringham, C.B., M.D., F.R.C.P., Colonel Sir J. R. Bradford, K.C.M.G., C.B., F.R.S., M.D., F.R.C.P., Colonel Sir W. B. Leishman, C.B., F.R.S., M.B., F.R.C.P., K.H.P., and Lieutenant-Colonel W. W. O. Beveridge, C.B., D.S.O., M.B.

Glasgow University.

At a meeting of the Glasgow University Court on June 8th, Principal Sir Donald MacAlister, who presided, said that he had to ask authority to make some additions to the equipment of Queen Margaret College, especially for students of medicine. The number had increased so greatly that all existing accommodation was already overflowed, both in anatomy and chemistry. He did not know what the necessary arrangements would cost, but as the number of women students of medicine had doubled during the year they must face the situation.

Replying to Dr. Hutchison, the Principal said the extension proposed took the form of internal arrangements.

The request was granted.

Girl Baby Murderer.

FROM Paris comes the story of an exceptional case of "infanticide" reported in a Cherbourg despatch announcing the arrest of a servant girl.

She is accused of poisoning her three-months-old baby, and from facts that have come to light it is alleged that, previous to murdering her own child, she experimented upon the seventeen-months-old baby of her mistress. Finding that its death aroused no suspicion, she proceeded to employ the same drug upon her own baby.

New Women's Hospital in South London.

THE new South London Hospital for Women, on the south side of Clapham Common, is to be opened by the Queen on July 4th, when her Majesty will receive purses for the support and upkeep of the institution.

The hospital has been built very simply, and none of the money needed for practical purposes has been spent on ornament. Georgian in style, of red brick and Portland stone, it has a practical beauty of its own. It fronts the common and London County Council tramway cars pass the doors. It was begun four years ago in response to a definite and increasing demand for a hospital for South London and the southern counties run and staffed by women.

A special feature will be paying wards where

women of limited means unable to pay the heavy charges of a nursing home may have privacy at a moderate charge. For a ward with one bed the charge will be 3 guineas; for two beds, 2 guineas; and for accommodation in an eight bed ward, divided into cubicles, the charge will be 1 guinea each.

There is accommodation for 80 patients. There are four general wards, a children's ward, the private wards already outlined, an isolation department, and also X-ray and pathological departments. The "Queen Mary Ward," which is completed except for its beds and medical equipment, is 70ft. long by 26ft. wide, and the windows allow for a perfect air current without draughts.

The Association of University Women Teachers have arranged to support a bed, and a similar arrangement has been made by the Teachers' League and a league of professional and business women. Lady Cowdray is giving all the beds required for the hospital, and other promises have been received.

University of London.

THE following candidates have passed the Third (M.B., B.S.) Examination for Medical Degrees during May, 1916:—

Honours.—Leonard G. Phillips, B.Sc. (*a, d*); Stanley Ritson, B.Sc., (*a, d, e*, University Medal). (*a*) Distinguished in Medicine; (*d*) distinguished in Surgery; (*e*) distinguished in Midwifery and Diseases of Women.

Pass List.—Louis A. Celestin, William M. Crombie, Christopher I. de Silva, John A. W. Ebdon, David S. Graves, Innes H. Pearse, Lloyd D. Phillips, Emma C. Pillman, Arthur L. Punch, Leslie N. Reece, Douglas G. C. Tasker, James W. T. Thomas, Arthur H. Turner, Sibil I. Welsh, Arthur W. Woo.

The following candidates have passed in one of the two Groups of subjects: Group I.—Grace M. Griffith, Cyril E. Petley, Basil Sampson, Alfred G. Simmins, Eric C. Spaar, B.A.

Group II.—Arthur W. Adams, Frederic V. Bevan-Brown, Robert M. Dannatt, Walter H. Lloyd, Violet I. Russell.

Royal College of Surgeons.

At a meeting of the Council of the Royal College of Surgeons on June 8th Sir Watson Cheyne, President, in the chair, the following members of the college, having passed the required examinations and conformed to the by-laws, were admitted Fellows:—

A. L. Pearce-Gould, M.D.Oxon, Univ. Coll. Hosp.; C. W. B. Littlejohn, Capt. R.A.M.C., M.B.Oxon., Melbourne Univ. and St. Bart.'s Hosp.; G. S. Miller, M.B.Lond., Guy's Hosp.; F. D. Saner, Camb., Univ. and Guy's Hosp.; and R. S. Lawson, Temp. Surgeon R.N., M.B.Edin., St. Bart.'s Hosp., not being a member of the college, was also admitted a Fellow.

The following candidates, having fulfilled the requirements of the surgical and dental sections of the Board of Examiners in dental surgery, were admitted Licentiate:—

A. S. Blacklaws, C. M. Bullpitt, Guy's Hosp.; J. J. C. Chiappa, Middx. and Nat. Dent. Hosps.; B. Eady, Guy's Hosp.; R. J. Ellis, Middx. and R. Dent. Hosps.; R. J. G. Halden, Guy's Hosp.; A. G. Hewer, Middx. and Nat. Dent. Hosps.; P. J. Hugo, C. H. Kidner, F. C. Lean and O. O. Lloyd, Guy's Hosp.; L. G. Lunnon, Middx. and R. Dent. Hosps.; H. P. Mabe, B. Micklethwait, Middx. and Nat. Dent. Hosps.; M. C. V. Thom, H. V. Vogt, M. H. Wermig and S. A. Woolf, Guy's Hosp.

The President reported that a meeting of the Fellows would be held on July 6th for the election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir Alfred Pearce-Gould, Mr. W. F. Haslam, and Sir Arbutnot Lane, and by the death of Mr. Stanley Boyd. He added that Sir Alfred Pearce-Gould and Sir Arbutnot Lane did not propose to offer themselves for re-election.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

LETTERS TO THE EDITOR and Original Papers intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of bona fides. These should be addressed to the Editor at the Offices of this Journal; if in Ireland, to the Dublin Office, 29 Nassau Street; from other parts of the United Kingdom, these should be addressed to the London Office, 8 Henrietta Street, Strand.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our official appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DEMOS (Rotherhithe).—You are mistaken in thinking we treat the subject as one of politics. It is a question of justice and fairplay to a profession which at present receives neither.

STATE MEDICAL SERVICE.

SPEAKING at the annual meeting of the Panel-Medico Political Union, Dr. W. Coode Adams (president) declared that the signs pointed to the establishment of a State medical service.

R.A.M.C. (Chesterfield).—We believe neither the German figures regarding the proportion of wounded who return to active service, nor the low average duration of incapacity.

£100,000 FOR SCHOOL OF MEDICINE.

SIR WILLIAM JAMES THOMAS, the Welsh colliery owner, has given £100,000 towards the establishment of a Welsh school of medicine.

POST (London, W.C.).—We note the opinion of the paper you forward. You will see from a quotation in this issue that the medical correspondent of the *Times* holds the contrary view.

QUEEN'S GIFT TO BRIGHTON HOSPITAL.

THE Queen has presented the Royal Pavilion Hospital at Brighton with a building to be used as a school for the teaching of some occupation to limbed soldiers.

X-RAY (Ealing).—We reviewed the book in last week's issue. Our experience coincides with your own.

GAS GANGRENE OF THE NECK.

DR. PAUL GUENOT has described two cases of gas gangrene of the neck, and the feature of special interest is the method he used in order to distinguish with certainty this affection from subcutaneous emphysema. The gas in gangrene is nearly always inflammable. This fact does not prevent the use of the thermo-cautery: on the contrary, numerous incisions should be made with this instrument, and most frequently a cure will be obtained.

O. T. S. (Loughborough).—We think the time has now come when graduated exercises may be commenced.

WORKMEN'S COMPENSATION ACT, 1916.

THE Secretary of State for the Home Department gives notice that, in consequence of the resignation of Dr. J. W. Batterham, one of the Medical Referees under the Workmen's Compensation Act, the appointment held by him will be vacant as from the 18th instant. Applications for the post should be addressed to the Private Secretary, Home Office, London, before July 1st. Dr. Batterham was attached more particularly to the Brighton, Lewes, Arundel, Chichester, Worthing and Hayward's Heath County Courts, Sussex.

RUGGER (Aldershot).—Such a fracture could be produced, but it is not the common result. The age does not negative it.

DENGAR.—We think your best course would be to write to the High Commissioner for S. Africa, Victoria Street, London, S.W., and explain the position.

WIRELESS (Birmingham).—Your query should be addressed to a paper dealing with such technical matters.

Meetings of the Societies, Lectures, &c.

FRIDAY, JUNE 16TH.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—5.30 p.m.—Annual General Meeting. Mr. J. Cantlie: Topography of the Liver in Rela-

tion to Liver Abscess. Dr. G. C. Low: An Interesting Case of Syphilitic Pyrexia in an Indian Native. The Value of a Positive Wassermann Reaction in Diagnosis.

Vacancies.

- County Asylum, Whittingham, Preston, Lancs.—Assistant Medical Officer. Salary £250 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent.
- Hampstead General Hospital, Haverstock Hill, N.W.—Resident House Physician. Salary £200 per annum. Applications to the Secretary.
- London Temperance Hospital, Hampstead Road, N.W.—Assistant Resident Medical Officer. Salary £120 a year, with residence, board, and laundry. Applications to the Secretary.
- Sheffield Royal Infirmary.—House Physician. Salary £120 per annum, with board and residence. Applications to Jno. W. Barnes, Secretary.
- Bury Infirmary.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.
- West Riding of Yorkshire: Middleton-in-Wharfedale Sanatorium, near Ilkley.—Lady Assistant Medical Officer. Salary £300 per annum. Applications to Francis Alcey Darwin, Clerk to the County Council, County Hall, Wakefield.
- Bournemouth Royal Victoria and West Hants Hospital.—House Surgeon. Salary £150 per annum, with board, lodging, and washing. Applications to the Chairman of the House Committee, Poole Road Branch.
- Darlington Hospital and Dispensary.—House Surgeon. Salary £160 per annum, with board, residence, laundry, etc. Applications to H. F. Creek, Secretary, 46, Greenbank Road, Darlington.
- St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City Road, E.C.—House Surgeon. Salary £150 per annum, with board, lodging, and washing. Applications to the Secretary.

Appointments.

CHERRINGTON, D. G., B.A., Cantab., M.R.C.S., L.R.C.P., District Medical Officer of the Rye Union.

Births.

- JULER.—On June 5th, at 24, Cavendish Square, W., the wife of F. A. Juler, F.R.C.S., of a daughter.
- KELLY.—On May 30th, at 89, Lower Barget Street, Dublin, to Lieut.-Col. W. D. C. Kelly, R.A.M.C., and Mrs. Kelly (née Wolseley)—a daughter.
- STODART.—On June 6th, at Tresillian, Topsham, Devon, the wife of Lt.-Col. T. Stodart, I.M.S., of a son.

Marriages.

PAVEY-SMITH—NORTHWOOD.—On June 3rd, at St. James's, Camberwell, by special licence, A. Bernard Pavey-Smith, Capt., R.A.M.C. (T.), younger son of Mr. and Mrs. A. E. Smith, of the Hollies, Nailsworth, to Elizabeth, youngest daughter of Mr. and Mrs. Northwood, of Spondon, Derby.

Deaths.

- AUSTIN.—On June 5th, at 25, Moorfield Road, West Didsbury, Manchester, Alfred Chalmers Austin, Capt., R.A.M.C., Medical Supt. of the Withington Institution, Manchester, formerly Medical Supt. of Hope Hospital, Salford, in his 40th year.
- FITZGERALD.—On May 27th, Charles Edward Fitzgerald, M.D., of 27, Upper Merrion Street, Dublin, Hon. Surgeon Oculist to His Majesty in Ireland, only son of the late Francis Alexander Fitzgerald, Baron of the Court of Exchequer, Ireland.
- GARNONS WILLIAMS.—Lost in H.M.S. *Hampshire* on June 5th, Penry Garnons Williams, Fleet Surgeon, R.N., beloved husband of Teresa Garnons Williams and youngest son of the late Rev. Prebendary Garnons Williams, Abercrombie-Brecon.
- GEOGHEGAN.—On May 31st, in the naval action off Jutland, Herbert Lyne Geoghegan, M.D., Fleet Surgeon, R.N., H.M.S. *Black Prince*.
- JOHNSON.—Killed in action on May 31st, 1916, on H.M.S. *Defence*, George Moore Johnson, M.B., M.A., eldest son of the late G. W. M. Johnson and of Mrs. Johnson, of 27, Beckenham Grove, Shortlands.
- NORRIS.—On May 31, in H.M.S. *Indefatigable*, Fleet Surgeon Hugh Leigh Norris, youngest son of the late Dr. Henry Edmonds Norris, of Charmouth, Dorset, and grandson of Captain Murray, R.N., C.B.
- PALMER.—On June 4th, suddenly, at Mundesley-on-Sea, Arthur E. Palmer, M.R.C.S., L.R.C.P., of Loughborough, Leicestershire.
- WILKINSON.—On the 5th inst., at his residence, 3, Lebanon Park, Twickenham, John Sebastian Wilkinson, F.R.C.S., eldest son of the late William Henry Beacon Wilkinson, F.R.C.S., in his 81st year.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, JUNE 21, 1916.

No. 25.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

IN connection with the subject of fevers, which is dealt with in another column, it is curious to read what Sir Thomas Watson (1792-1882), writing in 1838, had to say on the subject of the varieties of "Continued Fever." "Although fever is, as I have stated, a specific disease, it assumes divers forms; and so dissimilar are some of its phases that they might seem to belong to totally different maladies. These variations relate not only to individual cases, but to whole epidemics. In some places and seasons the inflammatory type predominates, marked by excitement of the sanguiferous system; in others depression of the nervous system, characteristic of the typhoid type, which is the prominent feature of the disease. Most generally of all, the disorder commences with inflammatory fever and ends with typhoid symptoms."

LATER on there occurs a passage which will surely be of interest to some of those who have been discussing a cognate question in our correspondence columns. "So that the differences observed in the aspect and phenomena of continued fever depend more, I conceive, upon an acquired disposition of the human body produced by some obscure general influence, and therefore affecting the entire London community, than upon any change in the essential nature of the disease, or in the virus which (as I believe) occasions it. The inverse relation between the rash and the intestinal ulceration is remarkable. When the one is prevalent the other is rare. It would seem, in conformity with Dr. William Budd's views, that the specific poison displays its elective affinities by settling sometimes upon the mucous glands, sometimes upon the cutaneous tissues, and sometimes by sharing itself, though unequally, between the two."

It does one good to read Sir Thomas Watson, if only because of his style. With the exception of Trousseau, he is probably the finest exponent of clear and graceful writing on medical subjects in any language. And if Trousseau be

really his superior, the superiority derives, in part at any rate, from the extraordinary flexibility of the French language, than which no more perfect instrument for the conveyance of thought has ever been evolved. The question of clearness of thought and language in medical literature has recently been discussed with some asperity in the correspondence columns of the *British Medical Journal*. The ball was opened by a letter from Dr. Mercier, who animadverted on the sloppiness of medical writing, of which he gave some instances. For this he was attacked by several correspondents, with the result which those who are acquainted with Dr. Mercier as a controversialist had no difficulty in foreseeing—namely, that his antagonists were badly but very gracefully worsted.

EXACTLY what Dr. William Budd's views were I do not know, but they would probably be found to be similar to those so ably expressed by

Dr. Midelton, of Bournemouth, in the letter which we published last week in reference to Professor Gougerot's article. Active counter-irritation is a therapeutic measure which has quite undeservedly fallen into disrepute. The seton, the blister, followed by savin ointment, the fixation abscess and even the homely mustard plaster are now seemingly fallen upon evil days. Yet there can be no doubt that they have a value in ridding the system of noxious elements which the blood is unable to void by the ordinary channels. Dr. Midelton truly says that Listerism has taught us to be unduly afraid of pus. The older surgeons used to speak of "laudable pus," by which they meant pus which was odourless. The term would be more suitably applied to the pus which, by means of a seton or fixation abscess, assists in debarrassing the system of toxic matters.

DR. MIDELTON might have gone further (he may possibly be induced so to do) and have developed the thesis, held by many balneologists, that the obscure pains which are known as "rheumatism" are due to insufficient activity of the cutaneous surface. It is a fact that these rheumatic pains are common in cold humid climates, and very uncommon in warm dry

Medical

Style.

Baths.

climates. The widespread testimony to the efficacy of thermal baths, light baths, sudorific baths, massage and similar surface treatments in the relief of these conditions points inevitably to a power in the cutaneous covering of exorcising the demon toxins which give rise to these troubles. On clinical grounds it is impossible to deny to the skin an emunctory power of the first importance, and there can be no gainsaying the position of experienced and thinking physicians that we have therein a curative potential which is unduly neglected by modern therapists.

MR. SEWILL'S letters on Medical Law Reform continue to attract the attention of our readers. This is as it should be, for the question is one in which the ordinary man takes but a languid interest. The languor is no doubt due to the feeling which prevails that, agitate as we may, in our spasmodic disrupted manner, nothing will ever be done. As Mr. Sewill has shown, the B.M.A., hitherto the only body which could have moved in these matters, has been worse than useless. The present is not, in one sense, a very suitable time at which to try and re-awaken interest, because so many of the interested have things more serious to think about than medical politics. In another sense, however, the present is the moment of all others. The quotation from the *Times* which we published last week affords abundant evidence of the reality of the danger to which I have for several weeks now persistently and insistently been calling attention. The intention to create a State Medical Service is in certain powerful quarters a fixed determination. The *Times* correspondent, who is doubtless inspired, says: "If the time for laying the foundations of a state medical service was ever ripe, it is ripe now." Let us therefore look to our defences.

IN any arrangement or bargain which is concluded between the Profession and the State, it is obvious that one item should be a drastic reform of the present lax laws by which the profession holds its position. Members of the profession are liable to severe penalties if they transgress certain very loosely defined rules, but unqualified practitioners may transgress all rules with perfect impunity. And yet the State does nothing whatever to remedy this state of matters. If it be the case, as we must assume it to be, that the rules which apply to qualified men are framed and enforced for the protection of the public, then from the point of view of that same public it is obviously the height of inconsistent absurdity to allow the unqualified to set these rules at naught without suffering the slightest inconvenience.

THE defence of the absurdity is, of course, well known. It sets forth that if a man is such a fool as to pay fees to an unqualified practitioner when there are hundreds who have laboriously qualified and are duly labelled as such, then in a free country he must be allowed to be a

fool. Such an argument might be convincing if it were consistently acted upon. But the State has always in some degree played the part of grand-mamma to the public, and in recent years its excursions in this direction have been increasing and not diminishing. In matters of the public health, for example, the State recognises that the policy of *laissez-faire* is an impossible policy, and it very properly declines to allow the individual to poison himself, his family or his neighbours, by indulging in a preference for bad drains or an impure water supply. In matters much less important than the public health the State takes the individual fool under its parental protection, and that in matters where it is the individual who suffers and not the community.

THE exponents of the "Confidence Trick," for example, always engage the attention of the police when they are careless in covering up their tracks. Here the individual suffers in his pocket only. The medical confidence trick, which is being openly played by thousands of quacks and charlatans upon the unfortunate whose judgment is obscured by disease and suffering, is regarded by the State with an indulgent smile. The citizen's property is protected while, in the sacred name of liberty, his person, and indeed his very life, are left at the mercy of a horde of predatory sharks whose only hope of success lies in the ignorance and gullibility of the public. If it is right to protect the fool against his own folly in the one case, the grounds for so protecting him in the other are simply overwhelming. I understand that the number of unqualified dentists practising in London alone reaches a figure which is astounding. I once knew one of this tribe. He amassed a large fortune without having ever had any training whatever, theoretical or practical.

THE Portsmouth Military Service Tribunal recently suggested that a possible outlet for the energies of conscientious objectors would be found at the Borough Asylum, from which so many of the attendants have gone to the war. The Court intimated that it would regard the work as of national importance. Dr. Devine, the medical superintendent, reported as follows on this suggestion:—"Conscientious objectors as a class, however honest they may be in their opinions, are unsuitable for the care of the mentally disturbed. They hold opinions contrary to those of the ordinary citizen; they are impervious to argument or criticism; they are egotistical and self-opinionated; and they reveal generally a type of mental constitution which forms the basis of psycho-neurotic symptoms and the various types of mental disturbance." With these views I cordially agree. If conscientious objectors are to find their way to lunatic asylums, it must be as inmates—not as attendants.

SINAPIS.

SIR JAMES THOMAS has given 1,000 guineas to endow a bed in Cardiff Hospital in memory of Lord Kitchener.

OF FEVERS.

CHARLES MUCHISON (1830-1879), who laid the foundation of such knowledge of fevers as we possess to-day, began his professional life as a surgeon in the Bengal Army. In 1856 we find him a physician to the London Fever Hospital, and from 1871 until his death he drew crowds of medical men and students to his lectures at St. Thomas's. It was in 1862 that he published his now famous "Treatise on the Continued Fevers of Great Britain." And yet it was not until six years later, taking advantage of the work of Sir William Thomson (afterwards Lord Kelvin), which established "an absolute scale of temperature," that Wunderlich (1815-1877) began to teach thermometry as a routine measure in clinical diagnosis. Sir Samuel Wilks has told us that the clinical thermometer was regarded as a novelty at Guy's Hospital as recently as 1870, an interesting fact which should not be regarded as any serious reflection upon Guy's. The pocket clinical thermometer we owe to Sir Clifford Allbutt. The present-day convenience of measuring the temperature under the tongue in one minute, instead of in the axilla in five or more, was rendered possible by the ingenuity of instrument makers.

The commonly accepted "normal" of 98.6° or 98.4° F. should not be, as it too frequently is, regarded as absolute. There are many people in quite good health whose temperature is frequently, if not generally, above this level, and there are many more who show a reading definitely below it. The story of the significance of subnormal temperatures remains to be written. It is a very interesting and instructive story whose *mise-en-scène* is the territory of the internal secretions. Of slight advances on the accepted normal there are few which are permanent, but a great many which are temporary. It is a good rule which bids us preserve our equanimity in face of a rise of temperature which does not exceed 100° F., but it is by no means a rule which is free from exception. A well-known teacher and examiner (if it was not Sir Samuel Wilks, it was one of his day) used to say that if a student omitted to include phthisis pulmonalis in his list of continued fevers, it was his practice to refer him to his studies. And yet phthisis pulmonalis is by no means always characterised by a continued elevation above the normal temperature. The elevation, even if it exist, which is not invariably the case, must often be sought carefully and even meticulously. More often than not, though otherwise absent, it is present after muscular exercise. The routine measurement at 9 p.m. and 9 a.m. may fail to reveal it, for it not infrequently lurks between the hours of 2 p.m. and 6 p.m. And then, there are those who satisfy themselves with looking for the elevation in the evening only, whereas perhaps the most characteristic thermometric sign of tuberculosis (some authorities even go so far as to regard it as pathognomonic of the disease) is a reversal of the usual order—namely, a morning rise and an evening fall.

It is the custom to regard malignant disease as

wholly innocent of thermometric vagaries, and many are the mistakes in diagnosis which have had their origin in too confident a reliance upon what is unquestionably a general rule. It is a fact to which the young practitioner should never allow himself to be blinded by the thumb-rule of hastily compiled text-books that carcinomata, especially of the abdominal viscera, are very often accompanied by a slight rise of temperature. It would, indeed, be correct to say that in a patient of the dangerous age, where the more obvious causes can be excluded, disorderly thermometrical excursions should always provoke a minute search for evidences of the dreaded growth.

In estimating the possible significance of a slight rise in temperature, it is always well to remember that children and women are apt to display an occasional instability of thermal record which is alarming to the inexperienced, an instability which is certainly much more pronounced in the upper classes than it is in the lower. In searching for an evening rise of temperature for the unmasking of tubercle, the investigator must not forget that such a rise is the rule rather than the exception in unmarried women for a few days before the menstrual period. The clinical thermometer is now as indispensable in the nursery as a powder puff in a ladies' waiting-room, and often has it occurred that the doctor has been summoned because nurse has taken Master Tommy's buccal temperature immediately after the urchin had surreptitiously imbibed a cup of hot milk. Children are now sent to bed with a thermometer in circumstances which formerly would have meant castor oil or the birch rod, or both. The use of the clinical thermometer by the laity is the cause of much blasphemous by the profession.

The term "fever" is generally used to denote one of the exanthemata. It is not so very long ago since "the Fever," meaning typhoid, was regarded as one of the necessary penalties of childhood and adolescence—much as measles and mumps are still too often regarded. In considering the list of recognised fevers it is surprising—and chastening—to realise how many there are the nature of whose virus is still unknown. Of these there are no less than ten, and, if we except typhoid, they are the best known. Scarlet, measles, German measles, small-pox, chicken-pox, typhus, mumps, rheumatic fever, yellow fever, and whooping cough are all diseases of whose pathology we are still ignorant. Having regard to this fact, we may claim credit to ourselves for being able to combat these conditions with a large measure of success. We are not yet in a position to provide against them in the same sense as we could provide against, say, enteric, cholera, diphtheria and malaria, were we given a free hand; but the application of general principles has been successful in lessening their incidence, and experience has taught us much in the matter of their rational treatment. The latest book on the subject (*a*) of fevers is from the pen of one who has had exceptional experience. It deals very largely with the aspect of treatment, which is approached from a very practical and helpful standpoint. Such a book was wanted. It will undoubtedly receive a warm welcome. It deserves one.

(*a*) "A Handbook of Fevers," by J. Campbell McClure, M.D. (London, 1914.)

CURRENT TOPICS.

British Prisoners in Germany.

THE medical aspect of the treatment of British prisoners of war in Germany receives some consideration in two White Papers which have recently been issued on the subject. They contain a record of the reports made by various representatives of the United States Ambassador in Berlin, who had visited the prison camps and questioned the men there detained. This country is deeply indebted to the American Ambassador and his staff for the humane work they have so regularly performed for many months in supervising the conditions under which our brethren in Germany are interned. The inspections took place between October 13th, 1915, and April 6th, 1916, and the conditions in the camps appear to be generally improved. Sanitation was pronounced good, and the health of the men generally excellent. There were some complaints as to insufficient clothing, irregular delivery of parcels, and inconsiderate treatment by the camp officials. As to food, it was found to be physiologically adequate in quantity and of satisfactory quality in nearly every case, equivalent to 2,700 calories per man per day; the chief objections to the ration being its monotony and the fact that the food was unpalatable because unaccustomed. Dr. A. E. Taylor, who visited Ruhleben, found the fault that the ration was deficient in fat. He urges the necessity of organisation of the food supplies sent to the prisoners from this country, suggesting a diet table which would adequately supplement the camp ration. He deprecates the lack of organisation as producing inefficient and wasteful results. A large number of the prisoners depend to a great extent on the supplies of food sent from outside or from home, and it is in the provision of the latter that he urges the need for organisation. With regard to the notorious Wittenburg camp, it is pleasing to know that the general health has been excellent since the disappearance of typhus. A new commandant had been appointed and a number of improvements had been made. Clothing, for example, was entirely satisfactory. Speaking of the conditions last autumn, Mr. Osborne, who visited the camp on behalf of the American Ambassador, says that the authorities regarded their charges not as honourable prisoners of war, but as criminals, whom only a régime of fear would keep in obedience, and he remarks that all evidence of humane and kindly feeling between the authorities and the prisoners was lacking. We welcome the statement of Mr. Jackson in regard to Döberitz and certain other camps that some prisoners bore testimony to the kind treatment received from German medical officers. We have never been willing to believe that the infamous medical officer of Wittenburg was typical of the medical profession of Germany.

Medical Aid to Rebels.

It is a question of some interest, and was recently of some practical importance in part of His Majesty's realms, to define the duties, moral and legal, of a medical man asked to give professional assistance to a rebel in arms. In a letter in our Correspondence columns in this issue, "Captain R.A.M.C.," suggests that Red Cross members of any belligerent body should be given the privileges to which the Geneva Convention entitles them. We are not sure that the Geneva Convention has considered the question of rebel forces at all, or that a rebel body in arms is entitled to the privileges of a recognised belligerent, but, at any rate, the question we are now discussing is some-

what different. In the conditions of civil warfare which existed in Dublin two months ago it must have happened to many medical men to give assistance to wounded persons who might or might not be rebels. It is certainly not the business of a surgeon to investigate too closely in such a case, and we are sure that few, if any, would refuse their aid. It is somewhat different when a medical man is asked to enter a position held as a rebel stronghold to give assistance to the wounded. We do not think that a medical man refusing such a call is guilty of any professional *lache*. A medical man is not bound to risk his life by going to the aid of those who are wilfully in arms against constituted authority. Moreover, on the legal point, it would appear that to give any aid, medical or otherwise, would be a crime. We do not profess to know the proper legal phraseology, but to succour the King's enemies is, we believe, against the law. Nevertheless, we do not think that public opinion would permit the giving of surgical assistance under such considerations to be treated or punished as a crime. The discussion of these points is, at the moment, academic, and we trust that never in our lifetime may a situation again arise in which it will again become practical.

Medico-Legal Aspect of Rifle-Bullet Wounds.

It is only a few weeks since in a note in our columns Dr. McWalter urged the need for review of the text-book teaching as to the effects of rifle-bullet wounds considered from the medico-legal aspect. The question of length of range may be one of much importance in deciding the guilt or innocence of an accused party, and the old dogmatic statements as to the marks of wounds received at close range must receive careful scrutiny. We are glad to see that Colonel W. H. Willcox is taking an interest in this question, for no one has a wider experience of medico-legal problems or greater authority in all such matters. Dr. McWalter found that with bullet wounds received at a range of about nine feet there was no charring of either the clothes or the skin. Colonel Willcox, in experiments with targets of white cardboard and of chamois leather, and with the ordinary service rifle and ammunition, found that at three inches from the muzzle of the gun there was no charring of either the cardboard or the leather, and only slight blackening. At a few inches more there was no blackening at all. It is to be hoped that these plain facts will become widely known, and that we will have no more foolish evidence to the effect that the range cannot have been short or there would have been more charring of the clothes.

Miners and Phthisis.

Two interesting reports are published regarding the connection between mining and phthisis. Dr. J. S. Haldane, at the annual meeting of the Institution of Mining Engineers, held on June 8th, gave an address on "The Health of Old Colliers." He said it was well known that colliers—*i.e.*, coal miners—suffered very little from phthisis. He pointed out the remarkable fact that the phthisis rate among colliers was not only much lower than in nearly all other occupations, but was even lower than in the exceptionally healthy occupation of farm labourers, despite advantages of pure air and relative segregation in the latter occupation. The low death-rate from lung disease among colliers up to the age of 55 was almost entirely due to their relative immunity from phthisis, and this immunity existed in 1850 just as now. Coal-dust certainly did not kill germs, but it had come to be regarded

by medical men as a preventive of phthisis. The lecturer added that if this was so, coal-dust in moderation was, on the whole, and despite explosions, an advantage to the safety of colliers. Town-dwellers and smokers might also take comfort to themselves in the thought that in introducing smoke particles into their lungs they were educating their lung epithelium to deal with really harmful foreign bodies.

The London smoker may now enjoy his sedative pipe as a preventive medicine without worrying too much over war economy.

The second contribution to the subject is the result of a preliminary inquiry, conducted by Drs. Watkins-Pitchford, A. J. Orenstein, and W. Steuart, into the prevalence of pulmonary tuberculosis among the natives working in the mines of South Africa. Here, of course, the industry is gold mining. The conclusions arrived at are:—(a) That the disease in its open, or communicable, stage is far less prevalent amongst natives actually working on the mines than has been hitherto supposed, only one case, out of 400 examined, having been detected. (b) That the problem of the control of the disease is not so formidable as has been anticipated; its total eradication from the mines, therefore, appears to be a feasible proposition. (c) That although 107 natives were examined whose term of employment underground exceeded two years only one was found with marked X-rays signs of silicosis apparently uncomplicated by tuberculosis; it seems, therefore, fair to surmise that marked silicosis is at least not more prevalent than pulmonary tuberculosis.

Thymus Death.

THE physiology and pathology of the thymus gland are still veiled in obscurity. The literature on the subject is scattered and incomplete, and any practitioner who is so unfortunate as to meet with a case of thymus death may be excused for his powerlessness to avert the fatality. Dr. Frederick Howard Falls has written an interesting paper on this subject, which appears in the current number of *Surgery, Gynecology and Obstetrics*. He reports one case of thymus death occurring in an infant four hours after birth, the child having breathed spontaneously and without difficulty for two hours, when cyanosis and progressive dyspnoea developed, the pulse slowing down to 30 beats per minute just before death. A *post mortem* examination showed the trachea and left lung to be compressed by a large thymus 4 cm. broad at its widest part and $5\frac{1}{2}$ cm. long. No abnormalities were found in the other ductless glands or lymphatic tissues, hence the case was included in the group of *status thymicus*. After a comprehensive survey of the literature available Dr. Falls comes to the following conclusions:—Partial thymectomy is of benefit in cases where the thymus alone is hyperplastic and the pressure symptoms are severe. Total thymectomy is contraindicated, for it is followed by rachitis and defective growth. The benefit of operation in cases of *status lymphaticus* with enlarged thymus is very doubtful. Tracheotomy and intubation are of no value in most cases because the pressure occurs too low down—as a rule where the trachea is crossed by the innominate artery. During operation the surgeon must bear in mind the possibility of aberrant vessels—in the case reported here the left innominate vein was found crossing the anterior surface of the thymus, instead of occupying its normal position deep to the gland. Dr. Falls pleads for a more systematic and complete record of all such cases in order that trustworthy material may be available for consideration.

Carnegie Trust and Infant Welfare.

THE promotion of the welfare of mother and child is a work of national importance, and throughout the country maternity centres and infant clinics are being established, mainly by voluntary effort. Naturally the extent of such effort varies throughout the country, and the action of the Carnegie Trust is a laudable attempt to make a complete survey of the whole subject. Dr. Hope, the well-known sanitarian, who is Medical Officer of Health for Liverpool, and Dr. Janet Campbell, an official of the Board of Education, are conducting an inquiry, on behalf of the Carnegie Trust, the object being to obtain accurate information as to the provision already made or in immediate contemplation in various public health areas for the care of mothers and infants. A schedule has been sent to all medical officers in England and Wales, asking information on essential points, e.g., conditions of general sanitation, housing accommodation, employment of women, and the nature of the industries of the locality. Figures will be tabulated to show the birth-rate at successive periods, the causes of infantile mortality, and other requisite information. A record is asked of the size and work of the M.O.H.'s staff, of hospital facilities, and of the measures taken to secure a pure milk supply. We have only partially indicated the scope of the interrogatories, but it is obvious that the results of such an inquiry will be of great importance, and may well form the basis of future legislation. The success of the scheme very largely depends on the cordial co-operation of the medical profession, and especially of the Medical Officers of Health. Such support, we feel sure, will be given in full measure.

PERSONAL.

THE King has been graciously pleased to appoint Dr. John B. Story, M.B., F.R.C.S.I., to be Honorary Surgeon-Oculist to His Majesty in Ireland, in the room of Dr. Charles Edward FitzGerald, deceased.

LAMBETH Council have publicly thanked Dr. Eleanor Gorrle for the able manner in which she has carried out her duty as *locum tenens* at the municipal tuberculosis dispensary for six months.

SURG. C. W. LEWIS, who went down in the *Queen Mary*, was well known in Edinburgh. A son of Professor Lewis, of Cape Town, he graduated M.B., Ch.B. at Edinburgh University in 1914. Later he joined the Navy as a temporary surgeon.

At the investiture ceremony held at Buckingham Palace by the King last week, Midshipman Henry D. Johnston, R.N., was one of the recipients of the Distinguished Service Cross. He is a son of Dr. M'Kenzie Johnston, Consulting Surgeon for Diseases of the Ear and Throat at the Royal Infirmary, Edinburgh.

MR. F. N. MOLESWORTH, solicitor, coroner for the Rochdale Division of Lancashire, has been unanimously elected President of the Coroners' Society of England and Wales for the ensuing year, and Dr. F. J. Waldo, coroner for the City of London and Borough of Southwark, has been elected Vice-President.

SURGEON-GENERAL T. P. WOODHOUSE, C.B., M.R.C.S., has been appointed a Knight of Grace of the Order of St. John of Jerusalem in England. He won Brevet promotion in the Royal Army Medical Corps for good work in the Boer War, and has received the Order of the Bath for the present campaign.

THE CHADWICK TRUST LECTURES.

LECTURE I.—PROCESSES OF DISINFECTION.

By PROF. SHERIDAN DELÉPINE, M.B., C.M., M.Sc.

Director of the Public Health Laboratory, University of Manchester.

Introductory Remarks.—The lectures which the Chadwick Trustees have asked me to deliver are concerned with some aspects of the prevention of disease; their object is therefore in harmony with the life work of the distinguished pioneer in whose memory these lectures have been instituted. The subjects which have been selected are of importance both to the soldier and to the civilian. Prevention of disease in the Army is based upon general principles that are applicable to any other community, but, of the methods based upon these principles, some which are suitable for a fixed civil population are not so well adapted to the circumstances of an army in the field. Some of the subjects we have to deal with are of a highly technical nature. I hope, however, to be able to place before you some interesting facts and considerations without troubling you with many abstruse terms.

To avoid the confusion which would be caused by mentioning the names of a large number of observers, many of whom are foreign, I will, though with regret, refrain from mentioning the workers to whom we are indebted for the discoveries which will be referred to. I regret this omission all the more in that most of the important discoveries to which I will have to allude are due to British, French, and Russian observers.

INFECTION AND DISINFECTION.

In the restricted medical sense, a person is said to be infected when harbouring some living animal or vegetable organism capable of producing disease. Such a person may be the means of infecting other persons by transmitting to them the infective organisms or disease germs. This transmission may be direct, by contact of person to person, as is usually the case with syphilis, or it may be indirect, as most commonly happens in typhoid fever, when the secretions, excreta or some other discharge from the infected person contaminate water, food, clothing, etc., which are afterwards used by other persons. The object of disinfection is to kill, or at least to render harmless, the infective organisms. As knowledge of the causes of infectious diseases has advanced the importance of indirect transmission has become more and more evident. This applies to such prevalent diseases as tuberculosis, typhoid and allied fevers, cholera, plague, tetanus, typhus, malaria, relapsing fever, etc.

The disinfection of infected persons is the object of certain methods of treatment, but disinfection, as generally understood, is chiefly applicable to the intermediaries, such as water, food, clothing, bedding, etc., by which disease may be transmitted from one person to another. This is of particular importance as regards to armies in the field.

General sanitary measures by which infection from person to person, infection of food, clothing, water, soil, houses, etc., is prevented, are undoubtedly more satisfactory than disinfection after infection has been allowed to take place; but a moving army cannot always choose its camping grounds, and have the benefit of methods of prevention which are appli-

cable to stationary populations. It is on that account that disinfection acquires a special importance in military hygiene.

Processes of disinfection must vary according to the nature of the infective agent and of the infected object or person. Thus destruction by fire which is undoubtedly a most efficient method is obviously inapplicable to the disinfection of living persons or valuable articles. The practice of disinfection is also determined by the ways in which infective organisms are transmitted from person to person, and as this varies according to the disease, a knowledge of the modes of infection must serve as a guide to the practice of disinfection. I propose, therefore, to discuss some of the most important processes of disinfection from the last point of view, and to do so in the time at my disposal I will select a few typical diseases.

DISINFECTION OF THE PERSON.

Syphilis is an instance of a disease which is almost always transmitted directly — *i.e.*, by the contact of one person with another. It is due to a protozoon called *Treponema pallidum*, which is found abundantly at the seat of infection and in the secondary lesions which are produced in various parts of the body. The treatment of this disease has for its object the killing of the parasite where it is located—that is, in the midst of the living tissues. Mercurial preparations, which have been used empirically for a long time, and various arsenical compounds which have come more recently into use, have that power, but most of these compounds are almost equally poisonous to certain cells of the individual treated as to the parasite. The careful experimental studies which have been conducted, both in this country and abroad, have revealed the fact that certain organic compounds of arsenic combine more readily with the *Treponema* than with the cells of the infected individual, so that by careful regulation of the amount administered it is possible to kill the parasite without seriously damaging its host. Treatment in this case, if completely successful, results in disinfection of the individual.

There is a remarkable resemblance between this method of treatment and the most primitive ideas regarding the treatment of disease. The contortions of the medicine man, the incantations of mediæval wizards, the herbs collected by wise and other women were all supposed to clean the body of disease, or devils which had taken possession of it. There are other animal parasites which can be dealt with in this way; among these is the *Treponema* causing yaws; the spirilla of relapsing fever of which European, American, African and Asiatic varieties have been described, are also affected by the same method of treatment which has also been used for sleeping sickness, a disease due to another group of protozoa, the Trypanosomes. In these diseases, however, transmission takes place through the intermediation of biting insects, so that the diseased individual is not the only field where the parasite can be attacked.

In the case of malaria, quinine has for a long

time been used for purposes of treatment, and its value is due to its specific action on the protozoa which cause the various types of malaria. Insects play also an essential part in the transmission of this disease. A knowledge of the life history of the parasite of malaria has led to methods one of which may be looked upon as based upon a process of disinfection. When a person is bitten by a mosquito a small spindle-shaped body, which constitutes one of the stages of development of the malarial parasite, is introduced into the wound with the salivary secretion of the insect; these parasites penetrate into the red corpuscles of the blood, then pass through various stages. A person whose blood is infected in this way is not, in ordinary circumstances, directly infectious to other persons, but when certain mosquitoes suck the infected blood, some of the parasites which are present in this fluid undergo further development in the walls of the stomach of the mosquito, and this ends in the formation of a large number of small elongated spindle-shaped bodies, many of which migrate to the salivary glands of the insect ready to pass with the saliva into the wound produced by the mosquito in the skin of its next human victim, who thus becomes infected.

Protection against mosquito bites, by the use of the mosquito net, may be looked upon as based upon the disinfection of air by filtration through muslin. The destruction of the larvæ of mosquitoes capable of transmitting the malarial organisms has been used in certain localities to prevent the spread of the disease, and this is effected by an interesting process. The mosquitoes in question belong to the genus *Anopheles*; the females lay their eggs in pools, or other collections of clear water; the larvæ arising out of their eggs float immediately under the surface of the water, and after undergoing various changes produce the perfect insect. If a thin layer of paraffin or some other oil is spread on the surface of pools in which larvæ are developing; and if this layer persists for at least half an hour, the larvæ are killed. It is obvious that draining off of all collections of water where larvæ can develop is still more effective. The reduction of the number of mosquitoes is followed by a diminution in the chances of infection. The destruction of a possible intermediate host before it has been able to act as a carrier of disease is certainly a process of disinfection as far as the water is concerned, but differs from others in that it does not deal with the disease-producing organism itself.

I shall have to speak more fully of the destruction of animal conveyors of infection. I must now refer to a process of disinfection of living tissues which is an adaptation of a natural process of defence against infection. The methods which I have alluded to, up to now, have been successful, in a practical sense, only in the case of diseases conveyed by inferior animal organisms, but lower plants known as bacteria, and which cause such diseases as tetanus, gaseous gangrene, anthrax, tuberculosis, typhoid fever, cholera, plague, etc., have so far proved more resistant to the direct action of chemical disinfectants than the tissues which they are infecting.

Up to now it has been found unsafe, in most diseases, to attempt to kill the bacteria infecting a person by administering chemical compounds having power to kill the infecting bacteria by their direct action. Compounds of iodine, salicylic acid and of some other substances may be said to be exceptions to the general rule, but even if it were so, this would not affect the general statement which I have made as to the state of our present

knowledge. But what we have so far failed to do by means of our purposely made drugs, the cells of which we are built up have for millennia done without our knowledge. It is only during the last forty years that our attention has been awakened to the importance of this work. Since then we have gradually learnt how to utilise the activities of those silent workers which have time after time protected us against infection.

The discovery of the means of harnessing our own cells for purposes of defence against disease germs forms the subject of some of the most fascinating chapters of modern pathology and therapeutics. Generally speaking, the methods to which I have just referred were primarily based upon the recognition of the fact that certain persons or animals are able to resist some infections and that an attack of some infectious diseases confers immunity from subsequent attacks. It was then found that this immunity was the result of the action of certain cells, some of which, known under the name of phagocytes, are capable of attacking, killing, dissolving or digesting directly, the infective germs causing the disease. In other cases the germs are acted upon by products circulating in the fluids of the body and which have the property of killing and even actually dissolving the invading germs. These substances which are said to be lysogenic or bactericidal are undoubtedly the products of cellular activity and give to the living cells the power to do, indirectly, what phagocytes can do in a more obvious and direct fashion. Certain cells and their products have, therefore, the power to disinfect more or less completely and rapidly infected living tissues.

What modern pathologists have learnt in the past few years is to take advantage of these natural properties and to increase by artificial methods the power which the cells have to fight and destroy infective organisms by direct or indirect processes of disinfection. This is one of the objects of preventive vaccination or inoculation. There are other aspects of this subject which do not fall under the head of disinfection and are outside the scope of this lecture. I need only mention vaccination against small-pox and against typhoid fever to remind you of the extent to which this method has been applied in the Army and of the great benefits which have resulted from this procedure.

Before concluding these general remarks upon disinfection of the person, I should say a few words about disinfection of the skin and of those cavities of the body opening on its surface. Complete disinfection of the skin though distinctly easier than that of internal living tissues is a matter of great difficulty.

Thorough scrubbing with soap and water, rubbing with alcohol and then washing with a solution of perchloride of mercury, is a method which has been used extensively by surgeons to disinfect their hands before operations. This process, which takes at least ten minutes when carried out thoroughly, should be repeated when the hands have been exposed to serious contamination. Solutions of hypochlorites (chlorinated lime or chlorinated soda) are more efficient than perchloride of mercury. A solution of iodine has also been used extensively for disinfecting the skin in regions where incisions have to be made for operative purposes. Even with these strong germicidal substances complete sterilisation of the skin is seldom obtained, but the superficial contaminations are removed, and this generally secures the necessary disinfection. Thorough washing of the hands with soap and water, with or without the weaker anti-

septics, such as Condy's fluid, carbolic acid, cyllin, izar, and many other popular disinfectants, is generally considered sufficient under ordinary circumstances.

The destruction of such vermin as fleas, lice, bed-bugs, itch-mites, which can convey disease from one person to another, may in some cases be effected while these parasites are located on or in the skin; this is specially the case with regard to itch-mites and lice. Petrol, paraffin oil, turpentine, benzine, carbolic acid, etc., have been found efficient in the treatment of the hair and skin. The lathering of the skin, more especially of the hairy parts, with cresol-soap and allowing afterwards the lather to dry on the skin, is another method. Sulphur and mercury are much older remedies, which still remain among the best. This is particularly true of sulphur and certain sulphur compounds in the treatment of itch. But with regard to fleas, bed-bugs, and body-lice, they are best attacked in their haunts outside the body of their victims. This will be referred to in another place.

Disinfection of cavities (as the alimentary canal), lined with soft mucous membranes by the direct action on bacteria of chemical disinfectants is practically impossible. The only thing that can be hoped is to obtain by these means reduction in the number of objectionable bacteria. This result is usually better obtained by natural means as when the alimentary canal is kept freely opened, foods favouring the development of certain bacteria are avoided, and beneficial organisms, such as some of those producing lactic acid fermentation, are caused to develop extensively in the intestine, thereby checking the multiplication of noxious bacteria; but none of these methods can be properly described as based upon processes of disinfection.

The difficulty of disinfecting the mucous membranes renders the task of dealing with carriers a complicated matter. These are persons who, after recovering from an infectious disease, continue to harbour infective bacteria in their nasal cavities, throat, alimentary canal, kidneys, bladder, etc. These bacteria may also flourish in persons who have apparently never suffered from the disease. "Carriers" play an important part in the dissemination of such diseases as diphtheria, scarlet fever, typhoid fever, and many other infectious diseases. They are best dealt with by segregation, lengthy treatment and careful watching.

As to the disinfection of wounds, it is now recognised that this cannot be satisfactorily effected by chemical compounds capable of killing bacteria by their direct action. If these substances were used in such quantity as to secure the death of bacteria, the damage done to the tissues would be so considerable as to make the remedy worse than the disease. The disinfection of wounds must be entrusted to the cells and fluids of the body; the action of these can be stimulated in various ways, some of which have been already discussed. Several of the antiseptics which have been so extensively used under the erroneous impressions that they were acting directly upon bacteria, undoubtedly owe their beneficial effects more to the action they have upon the tissues than upon their power of killing the bacteria present in wounds.

DISINFECTION OF EXTERNAL CONVEYORS OF DISEASE.

By external conveyors of disease, I mean anything, animate or inanimate, by which infective bacteria may be conveyed from a diseased person to one or more persons who thereby become specially liable to the disease caused by the infective germ.

In order to understand the ways in which these intermediaries act, it will be best to consider what may happen in connection with a case of typhoid

fever. The bacillus typhosus which causes this disease may be conveyed to any part of the body by the blood stream. It is present in large numbers in the intestine and also sometimes in the urine and in other secretions or discharges, with which it escapes from the body of the typhoid patients. In this way, it may contaminate the clothing, bedding, utensils and other articles used by the patient, also the drainage and sewage issuing from a house, hospital or town. Imperfect disposal of excreta from houses in urban or rural districts or in connection with camping grounds, trenches, etc., may lead to accumulations of highly infectious matter in temporary middens or cess-pools. Soil and water may be extensively infected by this material, either as a result of simple overflowing, or when the infected excreta are spread on various lands for the purpose of either simple disposal or cultivation. Through these various intermediaries a single case of typhoid fever may be the means of infecting a large number of persons.

The persons attending the patient or handling their linen, may, if not of clean habits, infect their hands and clothing, and in this way convey infection to milk, broth, jellies, ice-creams, etc. The patients themselves, when well enough to move about, are dangerous centres of infection, and this is specially true of persons harbouring the bacillus without showing any clear evidence of illness; these carriers are a source of serious danger.

Flies are to be feared for similar reasons. After crawling and feeding on infected refuse or excreta they come into houses and alight on various articles of food, such as milk, broth, etc., which they contaminate with typhoid bacilli. When the temperature and the articles are suitable these typhoid bacilli may, even when originally very few, multiply rapidly and render the food infectious. It is even held that when the flies are sufficiently numerous they may carry enough bacilli to produce infection.

The dust from infected articles or soil may be a source of dangerous contamination. Vegetables grown on polluted ground, shell-fish laid in infected estuaries, are also sources of human infection.

Infected water may be a conveyor of disease when it is used to clean vessels which are afterwards used to hold various articles of food in which the typhoid bacillus may multiply. When highly infected, the water itself may be directly infective. All this is not special to typhoid fever, but may be said with equal truth of other infectious diseases such as various forms of summer diarrhoea, food-poisoning, dysentery, Asiatic cholera and all other diseases in which excreta and other discharges contain, at some stage of the disease, the infecting agent. The disease germs may be disseminated chiefly through the agency of biting insects which suck the blood of the infected person, and afterwards bite other persons and infect the wound either directly or by means of their excreta or other discharges deposited in the neighbourhood of the wound.

In the case of bubonic plague the contamination of flea-bites by the excreta of infected fleas seems to be the commonest mode of infection.

In India the black rat (which is liable to plague epizootics) is the ordinary source of infection, and the rat-flea, which is capable of attacking man, is the carrier of the disease from rat to man. The body-louse conveys exanthematous typhus and relapsing fever. Bed-bugs have been accused of being the means of transmission of several infectious diseases, but this does not seem to have been proved satisfactorily, except, perhaps, in the

case of relapsing fever. The itch-mite is dreaded, not as a conveyor but as the actual producer of the very troublesome disease known as itch.

The examples which I have given will be sufficient to indicate some of the objects of disinfection, in what cases and under what circumstances it may be applied, and consequently what processes are likely to prove efficient. They show that it may be considered desirable to apply processes of disinfection to:—

- (1) The internal tissues or the integuments of an infected person (either patient or carrier).
- (2) The excreta and other discharges.
- (3) The clothing, bedding and various fabrics.
- (4) Various utensils and other objects.
- (5) Water.
- (6) Soil and dust.
- (7) Various animal and vegetable articles of food.
- (8) The destruction of various kinds of animal vermin, including intermediate animal hosts and carriers, should also be considered.

It will be obvious that if infected excreta and personal effects are allowed to pass out of the vicinity of the infected person the problem of disinfection becomes extremely complicated. Thus when excreta have been allowed to accumulate about a camp and to contaminate extensively the ground, dust, flies, and water, disinfection would be so costly and uncertain that the simplest way to deal with the difficulty would be to shift the camp, but this is not an ideal way of dealing with infection, nor is it always a possible one.

The complete disinfection of infected soil is, except when the infection is very recent and limited, practically hopeless, and must be left to natural agencies, such as light and dryness, assisted, when possible, by ploughing, drainage and the addition of large quantities of quicklime, chlorinated lime or other powerful disinfectants the addition of which may also be beneficial to the soil.

Disinfection of water supplies at home should always be rendered unnecessary by protection of the sources against pollution, but as this is not always found possible, purification of water by slow sand filtration or rapid coagulation and mechanical filtration are generally resorted to. Of late years disinfection of water by ozone, hypochlorites, ultra violet light, etc., has been adopted in various places. But these methods do not meet military requirements, except in garrison towns and barracks. For an army in the field the methods of sterilisation which have been found to be the most practicable are those based upon:—

- (a) Filtration of water through unglazed china, or other finely porous earthenware.
- (b) Sterilisation by heat.
- (c) Chemical treatment.

Of these, sterilisation by heat is the most reliable if properly carried out, but in order to obtain a sufficient amount of palatable, moderately cool water, cumbersome and heavy apparatus is needed. This is specially the case with French and German sterilisers. In the British Army some comparatively light apparatus has been used in which water is partly sterilised at a temperature below the boiling point. Each soldier might also boil water for his own use when circumstances permit it. The fuel may be a source of difficulty in the field.

Sterilisation by filtration through portable filters is slow when effective, and to obtain a sufficient yield it is necessary to use large batteries of porous candles and also pumps forcing the water through the filters under a pressure of some 40 lbs. to the square inch. This kind of filter stops bacteria entirely for a few days only, after which cleaning and sterilisation of the filter are necessary in order to restore full efficiency. The neces-

sity of frequent sterilisation, the comparative slowness of action and the weight of an installation sufficient for a large number of men, render the use of these filters difficult in the field. Portable rapid filters are unreliable and their efficiency is inversely proportional to their rapidity. These filters, however, remove many objectionable coarse impurities and some of the larger infective organisms, such as animal parasites, so that rapid filters are not without their use. Whenever applicable, good filters give excellent results, and their use has caused great reduction in the occurrence of water-borne disease in various armies.

Chemical treatment at first sight appears to have the advantage of convenience, provided always that a sufficient supply of the necessary chemicals is available. The best of these methods are based upon the well-known germicidal actions of chlorine and hypochlorites, bromine and iodine. Sodium bisulphate has also been proposed. If the waters to be treated were not, as they generally are, loaded with organic impurities, it would be easy to add the disinfecting agent to the water in such amounts as to secure sufficient disinfection without rendering the fluid unpalatable owing to the flavour imparted to it by the disinfectant. Unfortunately, the action of several of the chemicals used is comparatively slow, the waters to be purified very often contain a large amount of organic matter, and this amount is variable. The organic matter is acted upon by the disinfectant before the living bacteria are attacked by it; so that the amount of chemicals necessary to ensure disinfection should generally be greatly in excess of what would be required in the case of moderately pure water. Moreover, the proportion of disinfectant would have to be determined by the amount of oxidisable matter other than bacteria in each water. Until these difficulties have been overcome the addition of chemicals cannot be said to be an absolutely reliable process of disinfection of water for armies in the field. Notwithstanding this, chemical sterilisation should not be neglected when better methods are not available, for there is no doubt that a very small proportion of chlorine, bromine or iodine is sufficient to kill some organisms of low resistance, such as the bacillus typhosus and the cholera vibrio.

What has been said with regard to the disinfection of water by chemical means applies with greater force to the disinfection of excreta, soil, clothing, etc. With regard to soil and excreta, we have already seen that the free use and thorough admixture with the excreta of quicklime, or, better still, of chlorinated lime or chlorinated soda is useful, but popular disinfectants, such as tar products; carbolic acid, cresols and phenoloids, would have to be used in enormous quantities to obtain fully the result wanted. They have the advantage of reducing the number of flies, a result which can also be obtained by the use of mineral oil. The deep burial of fæces as practised, when possible, removes the danger of dissemination of disease by flies but may result in the infection of the water supply, if proper care is not exercised.

The prevention of malaria by the disinfection of pools infected by mosquito larvæ has been given as an example of a process of preventive disinfection. The removal, treatment, or destruction of manure and other breeding grounds of the house-fly have a similar object with regard to other diseases, such as typhoid fever and summer diarrhoea. The destruction of lice and their eggs in infected clothing, bedding, etc., is a more direct method of disinfection, particularly useful in the prevention of

typhus and recurrent fever, without speaking of the comfort of our soldiers. For this purpose a powder, of which the chief ingredients are naphthalene and creosote, and ointments containing respectively crude tar oil and mercury, have been used with success, although it is obvious that their action is too local and too slow to prevent migration of the parasite from person to person in crowded dug-outs. Various gases have been recommended for the disinfection of verminous clothing. Of these sulphurous acid is the only one which can be used safely and with fairly good results, but it penetrates slowly. Formaldehyde and chlorine are less efficient. Disinfection of clothing, blankets, etc., will be referred to again in connection with the use of heat, when the relative value of various agents will be discussed.

The prevention of plague, destruction of rats and of their fleas is a matter of primary importance, but is, unfortunately, difficult of attainment. Bacterial viruses have been used with variable success. Cats, ichneumons, dogs, have been called into the service of man. The professional rat-catcher has his share in the crusade against rats, which in Denmark has for some time received the support of the State.

ORIGINAL PAPERS.

HYPERTROPHIC VENOUS CIRRHOSIS.

By PROF. D. CASTAIGNE, M.D.,

Physician to the Cochin Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

I AM enabled to show you four patients, two women and two men, who have come to the hospital during the past week, all four suffering from venous hypertrophic cirrhosis with a variable degree of ascites.

This is not a mere clinical coincidence but is to be explained by the frequency of this particular disease, a frequency which is proportional to the prevalence of chronic alcoholism, its commonest cause. We must not forget, of course, that this affection may be due to other causes, but the fact remains that alcohol is usually the source of the mischief.

Hypertrophic venous cirrhosis is of comparatively recent birth as far as medical science is concerned. When Charcot established his classification of cases of cirrhosis he described two main types, on the one hand venous atrophic cirrhosis, corresponding to Laennec's cirrhosis, not accompanied by jaundice and of alcoholic origin, and on the other, biliary hypertrophic cirrhosis which is associated with jaundice, the cause of which is still unknown to us.

This conception long commanded assent, but, later on, Hanot and Gilbert showed us that alongside Laennec's atrophic cirrhosis there is a hypertrophic venous cirrhosis also of alcoholic origin.

Still more recently attempts have been made to discredit the necessarily alcoholic origin of this form of cirrhosis and to incriminate tuberculosis, syphilis and other infections. The investigation of these four cases is particularly interesting in reference to the share of the various factors in the genesis of the disease.

The characteristic feature of the disease is, to begin with, the marked enlargement of the liver. In most instances it reaches three or four fingers' breadth below the false ribs. In one of our patients, in presence of extensive eventration and the temporary absence of ascites, it happened to be particularly easy to make out a hard, granular liver with a thickened edge.

In these four patients percussion also reveals an enlarged spleen which can be felt below the ribs. This increase in size of the spleen is also an habitual sign in venous hypertrophic cirrhosis. The same remark applies to the collateral venous circulation which should always be looked for. This is more marked under the influence of fatigue and subsides more or less with rest and milk diet.

The belly is distended and prominent when the patient stands up, being rounded and globular, whereas, when he lies down, it assumes the classical batrachian shape (frog's belly). This is the case, at any rate, when there is ascites, and ascites is part of the ordinary syndrome of hypertrophic cirrhosis, though it may be wanting. Our four patients, however, all present, or have presented, ascites.

This woman, it is true, has no ascites at present, but when she was admitted for the first time, in 1912, she was punctured, and then withdrew seven litres of fluid. The puncture was repeated six months later.

These patients not unfrequently have an easily reducible umbilical hernia. One of our patients has this and, exceptionally, it is irreducible. The patient therefore is running the risks associated with strangulated hernia and, as happened in another of my cases, it provides a slit through which the fluid escapes, thus throwing open the door to possible infection. It is therefore advisable to perform the operation for radical cure under local anaesthesia, for not only will it obviate the risk of infection, but it will serve to evacuate the ascitic fluid.

The history of these four patients, on the other hand, shows that the venous hypertrophic cirrhosis runs a much slower course than atrophic cirrhosis. Once the latter is constituted it does not leave its victim much rest, whereas here, on the contrary, we have a patient whose general health is not by any means unsatisfactory, and who merely comes to us every year or two for the relief of the ascites.

When patients can be induced to adhere to a strict regimen the ascites disappears, and they imagine themselves cured, but, in reality, the cirrhosis is simply running its course without ascites. Then portal circulation is hampered, and this may lead to intestinal hamorrhage which may cause death.

The symptomatology of these cases may consequently be summed up as follows: more or less hypertrophy of the liver, which is hard and granular; the spleen is similarly increased in size and can often be felt on palpation and always by percussion. There is marked collateral venous circulation and other signs of heightened portal tension, especially troublesome piles. Lastly, these patients present more or less profuse ascites which, however, may be lacking for long periods. The course of the disease is less threatening than in atrophic cirrhosis, and it is compatible with prolonged life.

We must not on this account jump to the conclusion that hypertrophic cirrhosis is a mild disease. There are other forms of cirrhosis, also venous and hypertrophic, which run a rapid course, especially fatty cirrhosis, which is also manifested by a hard, enlarged liver, ascites and collateral circulation. Early in the case it may be difficult to distinguish these so-called malignant cases from the simple form. It may be necessary to have the patient under observation for some time in order to watch the evolution of the symptoms.

As a general rule, as soon as we perform paracentesis, the symptoms improve and the patient is able to leave the hospital and return to work, in which event we are dealing with a benign hyper-

trophic cirrhosis capable of improvement under diet and treatment.

In the graver cases, in spite of puncture, the patient becomes prostrated and has no desire to leave hospital. There is often bleeding from the gums or mucous surfaces or nose, the temperature is somewhat above normal and there is sub-delirium. These symptoms justify a grave prognosis and infer a rapid course.

These four cases belong to the mild forms and the patients' future may be looked forward to with confidence if only they will follow our instructions. We will now pass on to the question as to the origin of the disease in these cases.

I have pointed out that the exclusively alcoholic origin of the disease has been contested and that tuberculosis and syphilis have been incriminated. It was Jousset who set himself the task of proving that this cirrhosis was of tuberculous origin. He based his conclusion on the observed fact that guinea-pigs could be tuberculosed by inoculating them with ascitic fluid from these cases or with bits of the liver, and, lastly, examination of such patients often revealed the existence of tuberculous lesions in the lungs or tracheo-bronchial glands. Unfortunately, this line of argument is open to destructive criticism, because it would not be surprising that an alcoholic subject should contract hypertrophic cirrhosis and should secondarily become tuberculous.

As to the aetiological part played by syphilis, the Wassermann reaction has been found positive in these cases, but here again there is no incompatibility between cirrhosis and syphilis, each running its own course, though the latter may well exert a prejudicial influence on the former. Be this as it may, the fact remains that alcohol is by far the preponderating aetiological factor in the production of venous hypertrophic cirrhosis.

In all our four patients we have obtained their admission of ethylism, and they present the characteristic features. One has chronic matutinal waterbrash, another has terrible nightmares with a commencement of polyneuritis and marked tremor, a third has an even more pronounced tremor with a history of several attacks of delirium tremens, and so on.

With regard to the other possible causes of venous hypertrophic cirrhosis one displays signs of pulmonary bacillosis (a euphemism for tuberculosis), and another has had an indurated chancre but was properly treated and now shows no sign thereof.

In short, alcoholism is the chief, and probably the only, aetiological factor, and this will guide us in our treatment. These patients will only recover on condition that they abstain from every kind of alcoholic beverage, whether wine or cider, and it would be unwise to allow them to suppose for one instant that tuberculosis or syphilis had anything to do with their condition, otherwise you will not get them to adhere strictly to the dietetic restrictions.

A URINARY TEST FOR SYPHILIS AND ITS COMPARISON WITH THE WASSERMANN REACTION.

By CARL D. GRAY, M.D.,

Portland, Maine.

House Surgeon, Maine Eye and Ear Infirmary.

The form and variety of symptoms, either recent or remote, that may be produced by the *Treponema pallidum* are multiple. This same parasite causes certain metabolic changes in the human body, as is shown by the different laboratory methods, i.e.,

the Wassermann reaction, the gold chloride test, and the luetin reaction. With the exception of the latter, these tests require a well-equipped laboratory and reagents which are not within reach of the general practitioner. That some simpler test may be used which will at least strengthen or weaken the question in the physician's mind, is very probable. I wish to report a series of urinary examinations, part of which have been carried out in common with the Wassermann reaction.^(a)

The test is simple, requiring only a few test tubes, one of which must be graduated in cubic centimetres, and two stock solutions. A specimen of fresh urine, acid in reaction and normal specific gravity, i.e., above 1.016. A test for sugar, even in the smallest amount, should also be made, as its presence will interfere with the reaction. The reagents consist of: Solution I, dissolve 1 gram of resublimed iodine in chloroform or carbon tetrachloride; Solution II, phosphoric acid 10 per cent. To perform the test take 6 c.c. of fresh urine, preferably the early morning, and add 1 c.c. of Solution I and shake thoroughly for two or three minutes. The reaction depends upon some substance which inhibits the decolorisation of the iodine. After urine and iodine solution have been thoroughly shaken, the tube is set aside for a few moments, when the chloroform will settle to the bottom, being either pearly white (a negative reaction) or coloured pink or deep purple, when the reaction is positive and syphilis is to be suspected. One cubic centimetre of Solution II is then added, and the tube and contents are shaken the second time. If the chloroform is cleared and becomes white after standing three or five minutes, the test is negative.

The presence of sugar, even in the slightest trace, will produce a positive reaction, as has been proven by the examination of diabetic urines, and also by producing temporary glycosuria in healthy individuals whose urine had given negative tests and gave further negative reactions after eliminating a superabundance of carbohydrates from the diet.

A low specific gravity urine of the type produced by ingesting large amounts of water or the so-called "nervous polyuria" will give a positive reaction. To prove this, examinations of fresh urine from normal persons were made and were found to be negative; then later in the day, after several hours of labour with little or no water ingested, followed by copious drafts of fluid and a relaxation from mental strain, a second examination gave a positive reaction. This was illustrated in the case of several physicians after several hours' work in the operating room and in students following examinations. A positive result may also be caused by drinking one or two bottles of beer within a few hours of making the test. It seems necessary to inquire regarding the use of alcohol in this test for the same reason that it is necessary before taking blood for a Wassermann, the reverse result occurring in the urinary reaction. The presence of albumin, bile, indican, or blood has no influence upon the reaction. Cystitis, due to staphylococci, streptococci, pneumococci, or colon bacilli does not give rise to a positive reaction. Nor does gonorrhoeal urethritis unless complicated with a chancre. The reaction has been obtained from the urine of five patients where the diagnoses were made by finding the spirochaetes with the dark field illumination. In other cases the diagnosis has been from the history and clinical finding alone or as controlled by the Wassermann

(a) *New York Medical Record*, May 6th, 1916.

reaction. In two cases all three of these reactions were positive without any history of infection obtainable, the only lesion showing in the mouth.

TABLE I.

Diagnoses	No. Cases	+	-
Syphilis.....	50	50	0
Surgical conditions	55	1	54
Tuberculosis	15	0	15

Polyuria of nervous origin.....	5	5	0
Polyuria produced by the use of diuretics ..	10	10	0
Typhoid fever	5	0	5
	200	75	125

This short report is based on investigations made only during the past five months, but a glance at the two tables will give a slight idea of the results obtained. Urinary examinations were made in two hundred cases from patients suffering from different diseases as diagnosed under Table I., while it was possible to make a Wassermann for comparison, as is shown in the thirty-five cases in Table II. It has not been possible to obtain urines from cases of every description, and it is very likely that a more thorough investigation will show other conditions besides those noted below which give the reaction. With the results obtained it would seem that, while the test does not afford a

positive diagnosis for syphilis, it has its place in the examinations, and in certain cases might aid greatly in determining a more elaborate test.

The cause for the reaction is unknown as far as I have been able to determine. Physiological chemistry has not as yet solved all the problems or given cause for all reactions that occur. From results obtained in different tests we assume that certain substances, in some unexplainable manner, react with other substances and cause a definite result.

For illustrative purposes, I will cite a few case histories for comparison of the results tabulated in Table II.

CASE I.—J. R. D., man, age 31, widower. Wool sorter. Family history, negative as far as obtainable. Has three sisters, four brothers living and well, although one brother, aged 43, is nearly blind. Has always been in good health, never been under treatment for any cause. Complains of difficulty in seeing things after dark. First noticed this about five years ago. Onset gradual and vision perfect during the day. Examination showed the lids, sclera, cornea, and pupils normal. Through the ophthalmoscope both discs were pale, the vessels small, and pigmented areas all over the retina. O.D.V.=1. O.S.V.=1. Clinical diagnosis of retinitis pigmentosa O.U. was made. Urinary test was very positive and the Wassermann showed + + +. Under mixed treatment improvement was marked in three months.

CASE III.—V. M., woman, age 18. Single. Book-keeper. Family history: Father living, in poor health, cause of which the patient does not know. Mother died eight years ago of tuberculosis. One brother and one sister living and well. Four brothers and three sisters died soon after birth,

TABLE II.

Case	Clinical Diagnosis	Specific History	Iodine Test, Urine	Wassermann
1	Retinitis pigmentosa	None obtained	+	+++
2	Uveitis acuta specific	None obtained, except for an attack of rheumatism	+	+++
3	Interstitial keratitis and iritis specific	None obtained	+	+++
4	Interstitial keratitis and iritis specific	None obtained	+	+++
5	Interstitial keratitis	None obtained	+	+++
6	Interstitial keratitis	None obtained	+	+++
7	Interstitial keratitis	None obtained	+	+++
8	Interstitial keratitis	Chancre and rash in 1898, 2½-yr. treatment	+	—
9	Iritis	None obtained	+	+
8	Interstitial keratitis	None obtained	+	++
10	Paralysis, third nerve	None, except for a rash a couple of years before	+	+++
11	Interstitial keratitis specific.....	Gumma of clavicle three years before. Received 2.1 gm. neosalvarsan. Took mercury for several months 14 years before	+	—
12	Paralysis third nerve specific	None obtained	+	++
13	Parenchymatous keratitis	None obtained. Has typical notched teeth	+	++
14	Paralysis external rectus specific	Severe sore throat and rash two years before. Two miscarriages	+	+++
15	Absolute glaucoma.....	None obtained	+	+
16	Scleritis conjunctivitis	None obtained	—	—
17	Paralysis of superior oblique and inferior rectus	Attack of grippe about a month before.....	—	—
18	Parenchymatous keratitis	None obtained	+	+++
19	Episcleritis	None obtained	+	—
20	Chancroid	Sore on glands two years before. Bubo	+	+++
21	Not reported	None obtained except for three miscarriages at two months	+	+
22	Gumma of neck	Chancre several years before.....	+	+
23	Interstitial keratitis	None obtained	+	+++
24	Secondary syphilis	Ulceration of cervix and labia. Rash of face and body	+	+++
25	Interstitial keratitis	None obtained. Hutchinson's teeth	+	+++
26	Neurochoro-retinitis	None obtained, except for a sore throat a year before and slight rash on chest	—	—
27	Keratitis	None obtained	+	—
28	Neuroretinitis	None obtained	+	—
29	Interstitial keratitis and iritis.....	None obtained	+	—
30	Interstitial keratitis and iritis.....	None obtained. Hutchinson's teeth. Prominent frontal bone. Skin of hand dry and wrinkled ..	+	+++
31	Interstitial keratitis	None obtained	+	+++
32	Gumma of neck	None obtained	+	+++
33	Syphilis primary.....	None obtained. Mucous patches on labia	+	+++
34	Syphilis of throat	None obtained. Mucous patches in throat showing spirochaeta enlarged glands	+	+++
35	Keratitis and iritis specific	Rash three years ago	+	+++

cause unknown. Always been well till March, 1915. Has had severe frontal and occipital pain the last six months and lost some weight. Has lost all her teeth. Last March the left eye began to get red and painful. Photophobia. Vision lost within a week. Was in Canada at that time but returned home in the summer. In August the right eye ran the same course, and she lost weight and became almost totally blind. Entered hospital first of November. Examination showed the cornea dull, with dense infiltration. Pupils contracted. Deep circumcorneal injection. Perception of light only. Clinical diagnosis of interstitial keratitis and iritis. Urinary test positive. Wassermann + + +. Under treatment marked improvement has been noted, vision returning slowly.

CASE IV.—C. S., female, age 18. Single. Family history: Father died fifteen years ago of tuberculosis, age 33. Mother died four years ago, at the age of 42, from a shock. Two sisters living and always been well. Has had pneumonia eight times. Suffers from dull headaches and has been obliged to wear glasses. Otherwise always been in good health. In the middle of June, 1915, a rock struck her in the face and broke her glasses, a small piece going in the left eye and being removed. A week later the eye began to smart and burn, vision growing dim. A week later the right eye began to fail in the same way. Condition grew worse, till it was impossible to tell day from night. Examination showed the cornea deeply infiltrated, gray, and hazy. Pupil small and immobile. Patient had to be led about. Clinical diagnosis of interstitial keratitis and iritis was made. Urinary test was positive. Wassermann + + +. Under treatment the condition improved slowly.

CASE VII.—O. C. H., male, age 29. Family history negative. Had a chancre in 1898, followed two months later by a rash all over the body. Was told at that time he had syphilis. Took mercurial and mixed treatment for two years. Spent three months in a sanatorium for tuberculosis which involves the upper portion of the right lung. Three weeks before being seen (September 3, 1915) the right eye began to feel irritated, got red and painful. Photophobia. Examination showed the cornea dull, with infiltrated areas and deep injection. O.D.V.=0.5 O.S.V.=1.2 Diagnosis: Interstitial keratitis. Urinary test positive, Wassermann negative. Under treatment the condition improved rapidly.

CASE VIII.—Mrs. P. P., age 52. Married. Family history negative. Always been well. Mother of twenty children, three living, seventeen dying under 1½ years of age. The left eye has been sore and painful for the last two weeks (seen September 20, 1915). Cornea dull, infiltrated pupil, small posterior synechia. Diagnosis of keratitis and iritis. Urinary test positive. Wassermann + + +.

CASE XXIV.—Mrs. J., æt. 37. Family and past history negative. Ten weeks before (seen November 26th, 1915) had been troubled with ulcerations of cervix and labia, which had healed under local treatment. When seen, the face, arms and body were covered with a macular rash. Hair falling out. Mucous patches in throat. Diagnosis: Secondary syphilis. Urinary test positive. Wassermann + + +.

CASE XXV.—D. D., female, æt. 12. Family and past history not obtained, except that she had been operated on for enlarged tonsils and adenoids. Referred from school. Left eye red and deeply injected. Cornea dull and infiltrated. Notched teeth. Skin of hand dry and wrinkled. Rash

around mouth. Interstitial keratitis. Urinary test positive. Wassermann + + +.

In the limited number of cases which have come under observation, as is shown by the results obtained in Table I. of 200 cases, the reaction would almost seem a positive diagnosis for syphilis, were it not for the fact that other conditions may give the same reaction. The presence of sugar can easily be ruled out by any of the laboratory tests, and the use of any diuretic can be discontinued for a short period. The best method is to obtain a sample of the early morning urine, and do the reaction before decomposition has set in. A low specific gravity urine (below 1.015) usually gives a positive reaction, and the result of one examination in such a case should not be relied upon. In comparing the results in Table II., the most prominent point in favour of the value of the reaction lies in the fact that in no case in which the history or clinical findings suggested syphilis has there been a negative urine reaction and a positive Wassermann; while in six cases the iodine test was positive and the Wassermann negative. Three cases in which both tests were negative and in which specific infection was not suspected are also tabulated. Three or four cases in which the urinary test was positive and clinical finding suggested specific infection have been under treatment and with marked improvement, though there was no Wassermann obtained. One case, which is not reported in either table, gave a positive urine reaction, also the spirochætes were found from the initial lesion with the dark field illumination.

In conclusion, it seems that in suspicious cases this simple test may aid greatly, either suggesting the use of a better established test or the cautious administration of antisyphilitic treatment.

FASHIONS IN WOUND TREATMENT.*

By V. ZACHARY COPE, M.D., M.S., F.R.C.S.,
Surgeon to Out-patients, and Surgeon to the Orthopædic
Department, St. Mary's Hospital, Paddington.

THE subject before us is one of the oldest, if not the oldest, surgical problem which has taxed the knowledge of all ages. Wounds by various weapons have always been present with us, and though gunshot wounds are a comparatively modern innovation, the principles of treatment are the same.

If we go back to earlier civilisations we find that much more was known than we sometimes imagine. In the Grecian era a great principle was enunciated by Hippocrates, who enjoined that all contused wounds should be brought to suppuration. The dressings applied to wounds during the Roman times were very simple. Celsus states: "The first application to every wound should be a piece of sponge expressed out of vinegar. If the patient be unable to sustain the strength of the vinegar, wine must be employed. A slight wound is assisted even by the application of a sponge dipped in cold water. But in whatever mode it is applied it will be beneficial while it remains moist. Therefore it must not be allowed to become dry. A wound may be healed without exotic, rare or compound bodies." Later he states: "If the inflammation be severe, and there is no hope of union, we must have recourse to suppuratives. At this juncture the use of warm water also will be necessary, that it may dissipate the matter, soften the hardness, and accelerate the pus. When the inflammation shall have ceased the wound should be cleansed, and linen dipped in honey will answer this purpose best."

* A paper read before the St. Mary's Hospital Medical Society.

Galen had no very original ideas as to wounds, but he summarises his views as follows: "Our aim indeed is, in the first place, to bring the divided parts together; secondly, to fix sutures; thirdly, to take care lest any substance should intervene between the lips of the wound; fourthly, to protect the parts. As time proceeds we shall have another aim: to let out the matter which is done by opening the wound, etc. . . . We preserve the health of the part by drying substances."

The aim, then, of these old masters was to cause the wound to suppurate, and to give free drainage to the matter which formed. For centuries these principles were followed with modifications which the ingenuity of successive generations of surgeons thought fit to make. We gain an insight into the surgical practice of the learned Arabs in the Middle Ages by studying Albukasis. In the 84th chapter of his treatise he recommends that on the advent of inflammation a cotton dressing steeped in oil of roses, either alone or combined with astringent wine, should be applied to the part. In another place he states, with reference to a wound which bleeds too much: "If the wound is slight, and without complication, the treatment will be easy. It will suffice to spread over it a powder which will cicatrise the wound before contact with air alters it. This powder is composed as follows:—

"Take incense and dragon's blood, two parts; Lime either simple or slacked, three parts; mix them together and pass through a filter; fill the wound with it."

"One may employ lime alone if the other ingredients are not at hand."

One of the first men to strike out a new line in the treatment of wounds was Ambrose Paré, and it is interesting even now to read the story of the way in which his discovery was made. In the 11th Book of his works he states:—

"Now I had read in John de Vigo that wounds made by gun-shot were venenate or poisoned, and that by reason of the gunpowder. Wherefor for their cure it was expedient to burn or cauterise them with oil of elders, scalding hot, with a little treacle mixed therewith. But for that I gave no great credit neither to the author nor remedy, because I knew that caustics could not be poured into wounds without excessive pain, I, before I would run the hazard, determined to see whether the chirurgeons who went with me in the army used any other manner of dressing to these wounds. I observed and saw that all of them used that method of dressing which Vigo prescribes.

. . . It chanced on a time that, by reason of the multitude that were hurt, I wanted this oil. Now because there were some few left to be dressed I was forced, that I might seem to want nothing and that I might not leave them undressed, to apply a digestive made of the yolk of an egg, oil of roses, and turpentine. I could not sleep all that night for I was troubled in mind, and the dressings the precedent day, which I judged unfit, troubled my thoughts, and I feared that the next day I should find them dead, or at the point of death, by the poison of the wounds, whom I had not dressed with the scalding oil. Therefore I rose early in the morning. I visited my patients, and beyond expectation I found such as I had dressed with the digestive only free from vehemency of pain, to have had good rest, and that their wounds were not inflamed or tumefied. But, on the contrary, the others that were burnt with the scalding oil were feverish, tormented with much pain, and the parts about their wounds were swollen."

This observation of Paré led him to modify his

treatment, and in another place he lays down rules for the dressing of different wounds. When he suspected putrefaction he recommended substitutes which resisted putrefaction as contained in a remedy which he terms *Egyptiacum*, which was compounded of alum, verdigris, copper sulphate, rose water, and honey. These ingredients were dissolved in vinegar or brandy, and were inserted into the wound on pledgets or tents. When, however, no putrefaction was anticipated Paré used the extraordinary oil of whelps. This oil, which was widely used in the 16th and 17th centuries, was made by boiling two young puppies with earth worms, and adding oil of lilies, turpentine, and an ounce of aqua vitæ or brandy. One can imagine that the turpentine and spirit must have been the active ingredients. In Paré's book is mentioned another application which he himself had not tried, which was commended by Lorenzius Jaubertes, combining calcined mercury, camphor, oil of lilies, and spirit, which is interesting because it is the first record I have been able to find of an application containing a mercurial salt, which must have had antiseptic properties.

A century after Paré, Wiseman, that famous surgeon who lived at the time of the Civil War in England, was still recommending Paré's oil of whelps as a dressing for wounds. During the 18th century opinions as to wound treatment altered, and the summarised experience of a man who lived at the time of the Napoleonic wars is of interest. Guthrie, who had had exceedingly great experience of gun-shot wounds, wrote as follows:

"Nothing should be applied but a piece of linen or lint, wetted with cold water. This may be retained by a strip of sticking plaster or any other thing applicable for the purpose of keeping the injured part covered. A compress of linen or other similar substance, moistened with cold or iced water, when procurable, will be useful, and a few inches of linen bandage may be sewn on."

When a wound becomes tender a little oil, lard, or simple ointment may be placed over it. Cold or iced water may be used as long as cold is grateful to the sufferer. When it ceases to be so, it should be exchanged for warm."

Guthrie stated that fresh air and cold water were essentials and asserted that simple flesh wounds were cured generally in four weeks, and at any rate, the majority were healed in six weeks.

Coming a little later to the middle of the 19th century, an interesting discussion took place in 1848 at the Académie Nationale de Médecine, Paris. In this discussion such famous men as Roux, Maligne, Amussat, Velpeau, Huguier, took part. Less was said about the dressings than about the question of opening up the wounds and amputation. But I will quote the views of a few of these men.

Huguier, who stated that all the wounds treated by him healed well, recommended different treatment in February from that in June. In the winter simple dressings, lint, and ointment. When inflammation was manifested the same means were adopted unless the reaction was marked, in which case frequent fomentations were applied or poultices. In June more frequent use of cool fomentations and of irrigation was advised.

Amussat strongly recommended irrigations with tepid water and condemned poultices and ointments.

Piorry favoured simple lotions, gentle pressure twice a day to get rid of pus and *débris*, and bandages of diachylon.

Bégin, after condemning other methods of dressing, states: "The common method is that which reason and experience combine to advise.

Water at the ordinary temperature is the best possible local application."

An insight into the method of dressing wounds immediately prior to the introduction of antiseptics is obtained by glancing into "The Medical and Surgical History of the Great American Rebellion." In Vol. III., p. 867 of that ponderous work occurs the following:—

"The primary dressing of wounds and operations was always of the simplest character. A piece of lint or linen, held in place by the turns of a roll of bandage, is kept well moistened with water. The presence of maggots in wounds in the field and camp hospitals was frequently an annoying complication. Oil of turpentine and infusions of tobacco were used to kill these pests. Petroleum and kerosine oil was tried in some cases with markedly good effect, but the most effective remedy was a thorough examination of the dressing every two or three hours."

A few years after the American Civil War came the discovery of antiseptics, and the first great war in which these were used was the Franco-Prussian War of 1870-71. But even in that war the use of antiseptics was by no means universal. In the monumental work which German surgeons compiled at the close of that war it is pointed out that the antiseptic treatment of wounds according to Lister's method had not yet been completely adopted. Indeed, the statement is made that the treatment of the surgeons in the war of 1870-71 did not differ in essentials from that in the previous war of 1866. At the same time, a perusal of the methods of treatment makes it clear that Lister's influence was already being felt in a marked manner. The summary of methods of treatment is as follows:—

The wounds were dressed with dry or wet lint. For moistening one used cold or warm water simply, oil or carbolic oil, usually 1 in 10 or 1 in 15, camomile tea, camphorated wine, watery solution of carbolic in different percentages, permanganate of potash, bleaching powder, sulphate of zinc, sulpho-carbolate of zinc (seldom), and silver nitrate; or the lint was smeared with balsam of Peru.

Dressings of cod liver oil were favoured by the 11th Army Corps, and the healing of wounds so dressed proceeded quickly and often more speedily than by other methods. Arnica was also tried successfully. The writer sums up: "The use of carbolic was frequent at the beginning of the war and later became almost general. The dosing was uncertain, and the antiseptic-dressing method was, with few exceptions, still unknown. Judgment over the worth of carbolic varied, but the majority of the doctors were satisfied with its working."

Since the Franco-Prussian war, the antiseptic treatment of wounds has been developed. But in many cases proper opportunity for carrying it out has been wanting.

I have been dealing hitherto with the applications which are made to wounds. There are certain other points in treatment which are not so debatable. It has been generally agreed during the ages that gross foreign bodies are better removed, that hæmorrhage should be arrested, that the parts affected should be kept at rest, and that sufficient drainage for the exit of discharges should always be provided. At the same time, constitutional treatment has always been advised.

Before we discuss the methods which are in use at present for gun-shot wounds, we should get a clear idea of the condition of the tissues injured by a gun-shot. The wound is always contused; there is always superficial necrosis along the track of the missile, and bacteria are always implanted in the

tissues. It follows from this that in every wound which is to heal there must be a vital reaction of an inflammatory nature, and it must be remembered that the inflammatory process is characterised by two main features: the pouring out of fluid lymph and the emigration of leucocytes. The leucocytes are as necessary in the fight against bacteria and in helping to clear off sloughs, as is the serum, and no method of treatment which does not take them into account is adequate.

We must also remind ourselves that the vast majority of wounds get well under, or in spite of, any treatment, and that it is very difficult for any one man to form a true judgment of the relative methods to be discussed. Only by watching vast numbers of wounds of similar character, treated by different methods at the same time, can a fair judgment be formed. Since this is only possible to few, we shall probably be forced to decide by the weight of opinion of many different observers.

Now at the present day there are two methods of local treatment which are strongly advocated by different groups of workers. One aims at developing the natural body resources against bacterial infection; the other tries to destroy bacteria after they are implanted in the wound by external applications. The first is sometimes called the physiological, the second the antiseptic method of treatment. The antiseptic method is recommended by most surgeons. The so-called physiological method has been exploited by eminent bacteriologists, and, as you know, the main feature of this method has caused it to become known as the hypertonic saline method. The utility of true physiological methods of rest and drainage is not disputed.

I will deal first with the salt treatment. It consists in applying a 5 per cent. salt solution, sometimes combined with $\frac{1}{2}$ per cent. sodium citrate, to the surface of the wound, and thereby inducing a flow of serum which will wash out any microbes and destroy them. Stress is laid by the originator of the method on the maintenance of an outward flow of serum, this flow being maintained by what has been termed the "drawing power" of the salt. It is admitted that if the flow for any reason ceases the wound is placed in a favourable condition for the entry of micro-organisms into the tissues. Now I do not intend here to go into the physical problems which are at issue. But one may say that it would require more than one series of investigations from more than one laboratory to substantiate some of the sweeping conclusions drawn by the originator. Even the truth of the assertion that an increased flow of serum takes place after application of strong salt-solution is doubted by some observers, and I am not aware that any convincing experiments have yet been put forward to prove the assertion. The clinical estimation of amount of lymph discharged from a wound is difficult, and its comparison with the corresponding amount of pus which normally comes away from a wound treated by other means than hypertonic saline has never been carried out. On this point we must refer to a paper recently read before the Pathological Section of the Royal Society of Medicine by Dr. Parry Morgan, who shows that the experiments adduced to prove the drawing power of salt are open to a much simpler interpretation which excludes physical laws other than gravity and diffusion.

But even assuming that by means of the salt treatment an increased flow of lymph takes place that is but one factor in the fight against bacteria; an even more important factor is the action of the leucocytes which are kept back by the action of strong salt solution. Antiseptics, as they are

commonly used, interfere much less with the emigration of the leucocytes. The beef-steak appearance of a salt-treated wound is due to the almost entire absence of leucocytes. The opinion that in a wound infected with bacteria the presence of properly draining pus is something of which the surgeon should be ashamed is based on a misconception, as Parry Morgan has shown. Until the invading infection has been overcome the presence of pus is laudable as indicating a more complete local resistance against infection than the mere effusion of lymph. This fact, indeed, was recognised after a time by Sir Almroth Wright, who thereupon suggested that after a few days the strong salt solution should be replaced by normal saline.

Last year I gave this method a trial in several of my wards at the Third London General Hospital, and in the majority of cases it cleaned up the wounds well. In fact, for a time I thought it better than other methods, simply because the wounds looked cleaner and were free from pus. But on one occasion I had a reminder that bacteria were present, although the appearance of the wound was clean, by certain toxic symptoms, accompanied by fever and rigor, owing to the stoppage of the normal discharge, in a quite superficial wound, and it was brought home to me by this, and more especially by my knowledge of the research work of Dr. Parry Morgan, that these clean-looking wounds were not always as they seemed. I therefore gradually gave up the use of salt and adopted a neutral solution of hypochlorite, with the addition of a little citrate of soda. My purpose in adding the latter was to prevent any lymph clotting and stopping the normal discharge.

I will now give a few reasons which appear to militate against the salt treatment as constantly practised. Mr. Fleming has shown that the most frequent microbes of infection in gunshot wounds are bacillus aerogenes capsulatus, streptococci, staphylococci, coliform bacillus, and bacillus tetani in that order of frequency, and that as the wound progresses it is the streptococcus more than any other which maintains its hold. Every surgeon of experience will confirm the statement that the streptococci are the most dangerous microbes to be met with in wounds after the first day or two.

Now Sir Almroth Wright has shown that streptococci are able to grow in blood serum. He calls them serophytes, and Colonel H. M. W. Gray, in his recently-published paper, also states that streptococci thrive in serum. Yet the only defence that the salt treatment gives against streptococci is serum. That the originator of the method recognises this has already been noted. Thus he says: "But whether we have before us the complete or only the incomplete result, we have a wonderful improvement upon the state of the wound before treatment. None the less, the prospect for the future is not quite reassuring; in point of fact, we have here lying open and naked before us all the lymph spaces, and, moreover, elements of the lymph are disposed in the kakotropic arrangement, the fluid . . . in front and the leucocytes which will be capable of combating the streptococci behind. And, at any rate, so far as the superficial lymph spaces are concerned, there would now seem to be nothing to prevent microbial infection, save only that we have here an outflowing current."

Later he says: "The tide might easily turn and flow inward."

And again: "Let us merely put it down upon our tablets that it would seem to follow that we have in strong salt solution an agent which would be capable of arresting all suppurative processes."

Therefore Sir Almroth Wright suggests that normal saline shall be substituted for strong saline at a certain stage of the treatment. He observed that a film of pus appeared when normal saline was substituted, and argues that the normal saline has drawn the leucocytes out. But it is quite open for one to argue that a satisfactory pathological condition requires the presence of leucocytes, and that it is merely the taking away of the noxious strong salt which permits the leucocytes to advance. And we would do well to remind ourselves that bacteria can grow in normal saline, so that any stray remaining microbes might flourish.

The most damaging criticism that I have yet seen of the strong salt treatment comes from one of its most strenuous advocates—Colonel Gray. He describes the treatment by packing the wound with gauze into which salt tablets are placed, and designates such a dressing a "perfect dressing." We should now expect a free flow of lymph to occur. But, to our astonishment, it is stated: "Ordinarily, however, this tablet and gauze pack can be left in for many days, in test cases it has been left even for fourteen days. After the first twenty-four hours or so it often keeps wonderfully dry. Apparently this happens when the necessity for lymph lavage has passed. But no satisfactory explanation of this phenomenon has yet been recorded."

Here we have an open confession that frequently there is no continuous lymph flow, and incidentally an attribution to the salt of the power of choosing when it should stop the lymph flow. Now, as stated above, the stoppage of lymph flow in the presence of salt creates a most dangerous position of affairs, and the two authorities quoted seem to prove that the method they advocate puts the wound from the first to the fourth (or other day on which normal saline is substituted) in a defenceless condition against streptococci. To many it is not surprising that the dressing remains dry, nor that Colonel Gray has to put down a list of indications for changing the dressing, which include: Retention of pus, extension of inflammation, deterioration of the patient's general condition, and when the deep dressing becomes so offensive that it is annoying to the patient.

To sum up, a solution of 5 per cent. salt stops an essential part of the process of inflammation, and the much-lauded lymph flow is really pus without the leucocytes.

We must now consider antiseptics and their use for treatment of wounds. On the one hand surgeons of vast experience of surgery, both before and after the introduction of antiseptics, state, in no hesitating terms, that the treatment of septic wounds has been revolutionised by their use. On the other hand, bacteriologists and some surgeons maintain that they have not come across any satisfactory clinical or bacteriological evidence of the utility of antiseptics as employed in infected wounds.

Views so diametrically opposed as these call for thought. If the surgeons of experience are right, the laboratory experiments must have a fallacy somewhere in them. If the bacteriologist's observations are accurate, what shall we say as to the observing power of the many brilliant and distinguished surgeons who support the use of antiseptics for wounds. Let us go back again to the introduction of antiseptics, which was done by Lister in 1867. The first war in which the antiseptics were used even partially was the Franco-Prussian, and although, owing to the imperfect way in which antiseptics were then used, the Germans themselves preferred to class this war with the preantiseptic days, yet from what I have said

earlier, you will remember that carbolic and other substances of an antiseptic nature were used quite widely.

Comparing the mortality of wounds of the limbs in the war of 1864 with those of the war of 1870-1871, one is interested to find that the mortality in the case of the upper limb fell from 8 per cent. to 5 per cent. and in the lower limb fell from 12 per cent. to 10 per cent.

In the Russo-Turkish war of 1876-7 all the surgeons in the Russian Army spoke favourably of the modified antiseptic treatment then carried out. It was remarked that the antiseptic treatment did more than had ever been effected with any other. For, as Erichsen said, "It was by its means that Bergman and Reyher saved almost all their cases of gun-shot wounds of the knee-joint. The fate of the soldier is truly, as Nussbaum has said, in the hands of the surgeon who first attends him. If primary antiseptic treatment is at once used, he will have an infinitely better chance than by any other method."

In some of the succeeding wars, as well as in the present, it has been found difficult to carry out the antiseptic treatment thoroughly. But its value in keeping wounds clean has never been questioned. There are two methods of antiseptic treatment:—

1. To sterilise the wound completely before the microbes have had a chance to get a hold.
2. To diminish the surface infection and keep the wound clean after the bacteria have gained a hold.

The first method is only practicable within the first few hours after receipt of an injury.

The second method can be applied at any subsequent stage.

It is rather doubtful whether the complete sterilisation of the wound at the onset is often practicable, but I think there can be no doubt in the mind of anyone who has had experience of wounds, that antiseptics will keep them in a comparatively healthy condition.

Here we must refer to the interesting researches of Parry Morgan on the action of antiseptics in the presence of pus. By a series of ingenious experiments he has shown that some antiseptics—e.g., carbolic acid, are efficient even if there is a large proportion of pus present, though considerable time may be needed for their action; other antiseptics, for example hypochlorite solutions, act rapidly and efficiently when only a small proportion of pus is present. He states "it becomes plain that in appraising the value of an antiseptic the purpose for which it is used must be taken into account. For instance, for washing out a wound, when the antiseptic would be in great excess, hypochlorous solutions are very potent and carbolic acid comparatively weak. On the other hand, for an application in a dressing, when the pus would tend to be in excess, hypochlorous solutions would be practically useless, whilst carbolic acid, although it has the disadvantage of interfering with the activity of the leucocytes, is fairly efficient."

What are the objections brought against antiseptics?

1. That they do harm to the tissues.
2. That they do not penetrate far enough into the tissues.
3. That they are quickly neutralised by albuminous substances.

As to the first objection, in a gun-shot wound there is always superficial necrosis of tissue along the bullet track, and the addition of an antiseptic can do little extra harm, and will do much good

by killing the organisms which would be present in greater numbers in this tissue.

As regards penetration, it may well be that some organisms get deeply into the tissues, but the vast majority do not, and provided free drainage is made, and there is no damming up of discharges, the tissues should be able to look after themselves. It is rather curious that most writers on the subject omit any reference to the anti-bacterial action of the connective tissue cells.

In respect of the neutralisation of antiseptics by albuminous substances, if the wound is kept clean there will be little pus left to neutralise any antiseptic which is inserted, and still further we possibly have now at our disposal an antiseptic which combines with albuminous substances without much loss of its antiseptic property. I refer to the hypochlorites, especially the neutral form, which has been introduced by Dakin. Indeed, Dakin's solution seems to promise to be of the greatest value in many ways. It has been pretty well proved that in the strength used it does not damage the tissues, does not prevent the leucocytes from appearing, and forms an actively antiseptic substance.

If we were to believe all that its advocates say, we have found a perfect antiseptic. But one must be sceptical till further work has been done. At the same time in those cases in which I have tried hypochlorite treatment, especially when mixed with $\frac{1}{2}$ per cent. sodium citrate, I have been exceedingly pleased with the wonderful way in which wounds clean up.

I will summarise what I think is the best treatment for wounds very briefly.

1. Antiseptic dressing immediately.
2. Anti-tetanic serum.
3. Prophylactic dose of mixed vaccine and possibly an antiseptic vaccine at a later stage of treatment.
4. Rest to the part.
5. As soon as possible thorough drainage after removal of coarse foreign bodies.
6. Treatment by local applications of suitable antiseptics.

I cannot here go into the question of the method of application of antiseptics, but I should just like to give my opinion that continuous irrigation should not be continued too long in that it washes away the coagulable lymph, which in many cases is necessary for the repair of a wound.

MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my last letter I attempted to describe as briefly as might be the breakdown of the protective clauses of the Medical Act of 1858. The breakdown was gradual, but it was made evident within a few years by rulings in the High and Supreme Courts that the penal sections of the law were virtually reduced to dead letters. No sufficient attempt was made during all this period to bring the facts and the evils that arose from them before the Government. The British Medical Association drew up one or two Bills amending the Act. Whether these Bills were received or not I am not clear, but if they reached the hands of the Cabinet no result followed, nor have they ever been heard

of since. The Association had easy means of ascertaining that Bills of such kind could have no hope of a Reading in the House unless taken up by Government, and they had also easy means of informing themselves that no Cabinet would consider such a task unless it were forced upon them by demonstration of its urgent necessity. Reference to the indexes of the *Journal* would show that I frequently urged this upon the Association, and if I, a mere outsider without influence, could speak dogmatically on the question, it seems evident that the Association could more easily have got the same information. The subject was never fully discussed at the great annual meetings, and no attempt was made to address a resolution to the Government in the names of the distinguished representatives of every branch of the profession always present on these occasions. No demand was made for a Governmental enquiry, although it was evident (as I constantly urged) that this was a preliminary necessity.

The appointment of the Select Committee on Patent Medicines was brought about by the independent action of Members of Parliament and was urged by no professional organisation. An enormous service had, however, been rendered by the British Medical Association in preparing for such an enquiry. It had published periodically over a long period articles on Secret Remedies. These furnished the analyses of a great number of quack medicines and cited the pretensions of the advertisements. These articles were subsequently published in book form. They provided an unanswerable indictment of the trade in secret nostrums, but no attempt was made to bring these to the notice of statesmen and legislators who might have taken action upon them. When at last, after pressure by members during several Sessions, the Government undertook to set up an enquiry, no attempt was made by the British Medical Association to enlarge the very narrow limitations which had been put round the investigation. The question of practice of unqualified pretenders under the cover of the traffic in nostrums and apparatus was entirely left out, and the main question of practice under false pretences by uneducated quacks was also omitted. It seems unquestionable that the enquiry might have been made once and for all complete if the matter had been pressed authoritatively upon Government. The Select Committee had been brought into only the lightest touch with these latter problems. They were not called upon in any way to refer to them, and yet in a passage which I have previously cited from the Report, they speak of "swindles like Dr. —, the 'eye quacks,' the 'deaf quacks,' the cancer curers, the consumption curers, the electric-belt makers, the curers of rupture without operations, and 'fakirs' generally." When Parliament resumes its normal functions the report of the Select Committee must be pressed forward. It will give the greatest support to the demand for an enquiry into the question of practice by unqualified persons. It will be possible to prove the case for legislation by examination merely of a few illicit practitioners. It is, however, probable that the threat of summons before a Tribunal would cause the flight of a great many of these gentlemen, especially those hailing from Germany and America. The whole class would easily be shown to be composed of ignorant men devoid of medical knowledge. The enquiry would also drag forward the considerable number of qualified men, struck off the Register for infamous conduct, who now serve these fraudulent masters. The citation from the report which I have made was in reference to the amount spent in newspaper advertisements of patent medi-

cines, and the Committee stated that this amount did not include the sum expended annually by the classes of quacks which they enumerated. The total sum divided among those papers and periodicals which accept quack advertisements cannot be, if at all, much less than £3,000,000 a year. Most of the papers are fully aware of the nefarious character of the trades whose profits they are sharing. In my first letter of this series I stated that the conduct of the bulk of the Press (there are, of course, many exceptions) in this connection had all along been scandalous, and had become more than scandalous since the publication of the Select Committee's report. I must, however, reserve the discussion of quackery and the ethics of journalism to another and final communication.

I am, Sir, yours truly,
The Old Rosery, Earlswood. HENRY SEWILL.
June 15th, 1916.

RE B.M.A. AND TRADE UNIONISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—That portion of the medical profession, if I may venture still to call it such, is deeply indebted to you for the clear and incisive way in which you deal with those members of the B.M.A. who are taking up a hostile attitude to such of their *confrères* who do not see eye to eye with them. The other day I was sitting in a public tram when I came across one of these gentlemen, who attacked me and told me that I was a *blackleg*, and ought to be ashamed of myself for having left the B.M.A. He went further, and accused me of having left it because I was passed over as president of the local branch. He said that every man ought to belong to the trade union of his *trade*. He then went on to say that I had left on account of the subscription being raised. I told him that I had belonged to it for twenty-five years and that I had left it because it had, I thought, stultified itself and the profession by the way it had behaved, and I thought that it had mismanaged and misspent the money which it had in trust; that I had never sought any honours, and it was not my nature to seek such. I might have pointed out that a man who seldom took the trouble to attend the meetings certainly cannot be accused of expecting any honours, or seeking them. I was not surprised at being addressed as a blackleg, and must admit that I regarded it as a compliment under the circumstances, but I think I had reason to take exception to the time and place chosen to use such an opprobrium and to attribute such mean causes for the step taken.

I personally think that a studied system of black-mailing and intimidation on the part of an organised oligarchy, who utilise honourable positions to benefit themselves chiefly, is fast approaching, and that it is time that steps should be taken to enable those who do not wish to form themselves into a *trade* to protect their interests. This can easily be done, as in many cases the gentlemen who aspire to, and attain, the posts of honour in this society are generally, in provincial towns, men who are attached to the local hospitals, and who think that it is to their interest to keep in with all men if possible, and who thereby throw an undue weight and professional status on a portion of the profession who are showing themselves unworthy of their trust. By a system of organisation amongst those who do not approve of the methods adopted by the B.M.A. and their ilk, it would be easy to combat and put an end to their nefarious methods.

I am, yours truly,
A BLACKLEG.

Bournemouth, June 15th, 1916.

THE CIVIL RIGHTS OF MEDICAL PRACTITIONERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You remember that the English College of Surgeons fought valiantly for the civil rights of one of their members who was despitely used by the governor of one of the Colonies. I submit that at the present moment a duty lies—firstly, on Irish Colleges and Universities, and, secondly, on the Medical Associations—to see that any medical men or women imprisoned or detained as a result of the recent rebellion shall have all reasonably proper treatment.

We in Ireland have contributed so great a proportion of our members to the R.A.M.C. that we can afford to claim special consideration for those of our brethren who have given service to the rebel side.

Furthermore, it is a matter of the gravest moment that the "Red Cross members" of any belligerent body should always be given those privileges to which the Geneva Convention entitles them.

I am, Sir, yours truly,
Dublin, June 13th. CAPTAIN, R.A.M.C.

TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

MEETING HELD THURSDAY, JUNE 8TH, 1916.

Dr. M. HANDFIELD-JONES in the Chair.

JOHN D. MALCOLM, F.R.C.S.Ed., showed a CASE OF STRANGULATION OF THE UTERUS BY TORSION OF THE BODY ON THE CERVIX—SUPRA-CERVICAL HYSTERECTOMY—RECOVERY.

ROTATION of the whole uterus with an ovarian or uterine tumour is not very common, the displacement being at most something over half a revolution. I have never seen complete arrest of the blood supply from this cause, and I have not before seen or heard of a case like the following.

On November 3rd, 1915, a rather frail lady, æt. 70, married, but never pregnant, complained after dinner of pelvic pain. Next morning she was better and took her breakfast in bed as usual. She could not get up afterwards because the pain became so intense, and it was then accompanied by vomiting. Towards evening the temperature rose to 101° F. I saw her late that night with Dr. Hewetson and Dr. Watson, of Reigate, and found a hard, round pelvic tumour, median in position, and about four inches in diameter. Behind this and also in the middle line lay an elongated irregularly-oval mass measuring apparently about 3½ inches from above downwards by 1½ inches from side to side. This was fairly soft but of uneven consistence. It seemed to be attached to the hard mass in front, and there was a soft short cervix uteri below. The rectum was firmly compressed, but the abnormal parts seemed to be slightly movable as one mass in the pelvis. They were very tender and therefore seemed larger and more fixed than they really were. It was known that a fibromyoma existed before the patient's menstruation ceased, and it was easy to surmise that something had twisted, but the condition behind the hard tumour puzzled us all.

On opening the abdomen a fibromyoma was seen attached to the left anterior upper part of the uterus. This and the uterine body had revolved one full

turn on the cervix, the lower end of the body being so tightly twisted that the parts above were of a deep blue-black colour, and although it was only 16 hours after the pain became severe and about 28 from its first onset, the conditions caused a distinctly offensive odour.

Supracervical hysterectomy was performed, the left ovary and fallopian tube, which were raised by the new growth above the constriction, were taken away. The right ovary and the greater part of its tube were below the constriction and were not removed. Considerable trouble from flatulent distension followed the operation, but otherwise recovery was good although slow.

The specimen which is exhibited shows that the uterine body was as big as that of a woman in the prime of life, but it is obviously enlarged by congestion. The softness of its tissue, due to senility, evidently facilitated the attenuation necessary to make this viscus sufficiently narrow to become strangulated by torsion.

Dr. CUTHBERT LOCKYER welcomed the publication of Mr. Malcolm's case of acute torsion of the uterine body, because it demonstrated a rare condition, and one which presented extreme difficulties in diagnosis. With reference to torsion of the corpus uteri generally considered, it was known that a twist of the body on the cervix through as much as 90 deg. could occur without producing any symptoms suggesting its presence. In no one of eight cases recorded by Kelly and Cullen had the torsion given rise to any special symptoms, and in one of these the uterine body, which was abundantly fed by omental blood-veins, was rotated through 180 deg. The torsion usually occurs through the isthmus, which gradually undergoes atrophy and forms a sort of pedicle for the body above. This pedicle may ultimately be severed completely from the cervix below, as was shown in the case of Bastinelli of Rome. An account of this case is published in Kelly and Cullen's work on "Myomata." The patient was aged 53. A fibroid had been known to exist for twenty years, and there had been several attacks of severe peritonitis. At the operation it was found that the myomatous uterus was completely severed from the cervix owing to atrophy of a torsioned isthmus. The uterus was not acutely strangulated as in Mr. Malcolm's case. On the contrary, it was adherent to the anterior abdominal wall, from whence no doubt it derived nutrition. The appendages were rolled up to form a single pedicle attached to the floor of the right iliac fossa. The pelvis was as empty as if a supravaginal hysterectomy had been performed. Clinically, therefore, cases of *gradual* torsion are sharply differentiated from those of *acute* torsion.

Mr. Malcolm's case well illustrated the latter condition, and, as supplementing the remarks of the exhibitor, Dr. Lockyer referred to the following cases of acute torsion:—

(1) Poth's case shown in Berlin, May, 1913. The patient was aged 56. She had suffered from severe abdominal pain for 21 years, and was known to have a large abdominal tumour. The abdomen contained blood-stained fluid. A pedunculated subserous myoma with a twisted pedicle was removed, and then the uterus itself was found to be twisted upon its neck through 360 deg. from left to right.

(2) In August, 1914, Drs. Eden and Lockyer operated on a case in which a similar condition was discovered. The large myomatous uterus was blue-black in colour, and both appendages were engorged with blood and thrombotic.

(3) Steinbuchel's case, in which severe internal hæmorrhage resulted from rupture of one of the vessels which was severed during torsion of the pedicle.

(4) Grunert's case, where a moderate degree of torsion of the uterine body (90 deg.) led to very acute symptoms simulating the acute torsion of an ovarian cyst.

(5) Jolly's case, in which a torsioned myomatous uterus became impacted in the pelvis and led to displacement and blocking of the ureters, double surgical kidney, and death from uræmia.

The causation of torsion of the uterine body is a subject for speculation. When, as in Poth's case, the pedicle of a large myomatous uterus becomes twisted it is not difficult to understand that a small uterine body lying below may share in the process, especially since it is acknowledged that once torsion has taken place it is apt to be progressive. In a case like Mr. Malcolm's, where the tumour has a wide attachment to the uterus, it must be assumed that in trying to rise out of the pelvis it meets with resistance, to overcome which rotation of the tumour and of the uterine body is brought into play. The fact that these cases occur in women over 50 years of age is noteworthy.

Mr. MALCOLM replied.

Dr. F. J. McCANN showed a specimen of pregnancy in a large fibromyomatous uterus.

The PRESIDENT, Dr. HERBERT WILLIAMSON and Dr. CUTHBERT LOCKYER discussed the specimen.

Dr. F. J. McCANN showed a specimen of "soft fibroma of the vaginal wall."

Dr. ANDREWS said that he had had a somewhat similar case, which he had described at a meeting of the Society several years previously. The patient complained of a bulging of the anterior vaginal wall which had been mistaken for a cystocele, and the operation of cystopexy had been performed by a general surgeon. There was a large semi-fluctuating mass presenting at the vulva. Dr. Andrews made a longitudinal incision through the vaginal mucous membrane, and enucleated a soft œdematous fibroid about the size of a man's fist.

Dr. HUBERT ROBERTS said: "I have also met with a case very similar to that described by Dr. McCann but (as in Dr. Russell Andrews' case) mine occurred in the anterior vaginal wall. It was really a fibro-cellular tumour of the utero-vaginal cellular space and not a vaginal fibroid. The patient was aged 47, single, and was admitted to the hostel of St. Luke, Fitzroy Square, W., on November 12th, 1912, under the care of Sir Francis Champneys, who removed the tumour. I was then the visiting medical officer. The patient's chief complaint was trouble with micturition for the previous 12 months, with occasional attacks of retention of urine. On examination a smooth mass was found bulging the anterior vaginal wall as high as the fornix, convex in shape, and almost occluding the passage mechanically. The cervix could just be felt far up behind this mass. Bimanually a 'cake-like' mass, measuring 4 in. by 4 in. and 2 in. vertically, could be grasped. It was firm but not elastic. A bladder sound passed 6 in. in front of the mass. It was removed under anæsthesia by incising the anterior vaginal wall, and was found to be quite free of the urethra, and to occupy the cellular space between the bladder and cervix. It was fairly easily enucleated from its cellular bed, and had the appearance of a soft fibroid. It weighed 7 ounces. The cavity was plugged with gauze as bleeding was fairly free. The patient did well, and has never had any recurrence to date. Sections of the tumour showed it to consist mostly of fibrous tissue and not muscle (Van Gieson stain). Very few cellular elements were found. It appeared to be an innocent growth and not a sarcoma."

Dr. McCANN replied.

Dr. H. RUSSELL ANDREWS read a short communication on three cases of

HÆMATOMA OF THE ABDOMINAL WALL.

(1) A patient 8 months pregnant was admitted to the London Hospital, very ill, with pulse rate 135 per minute, temperature 101° at night, respirations 28-36 per minute, with severe cough and much dyspnoea. The pregnant uterus was felt in the left half of the abdomen, while the right half was filled by a large, exquisitely tender, tumour. A premature still-born child was born 30 hours after admission. The patient's general condition was such as to contra-indicate abdominal section until several days after her admission. A diagnosis of ovarian cyst, with localised peritonitis, was made. At the operation the tumour was found to be a hæmatoma, containing nearly 2 lbs. of blood between the right transversalis muscle and the transversalis fascia.

(2) A patient was sent into the London Hospital with a diagnosis of twisted ovarian tumour. For two weeks she had had a painful swelling in the left side of the abdomen, after carrying a pair of steps upstairs. Dr. Andrews made a diagnosis of hæmorrhage into, or round, a desmoid tumour in the left rectus. The tumour proved to be a hæmatoma in the left rectus muscle (spreading out a short distance between the transversalis muscle and the transversalis fascia).

(3) A patient under the care of the late Dr. Maxwell had a painful swelling on the left side of the abdomen, which had appeared a week previously with coughing. This swelling was found to be a hæmatoma, which had apparently originated between the left rectus and tracked outwards. Dr. Andrews referred to four previously recorded cases of hæmatoma of the abdominal wall. Four of the seven patients were pregnant, and four complained of cough.

The PRESIDENT thought that these cases must be very rare, as he had seen only one instance during a somewhat long experience. The patient, a primipara, was admitted to the medical ward of St. Mary's Hospital suffering from an attack of typhoid fever. The pregnancy was advanced to the middle of the seventh month. About the third week of the fever labour pains came on, and a dead fœtus was expelled. During the third stage pain was complained of in the region of the right rectus muscle about the level of the navel. It was noticed that a lump had formed here about the size of an egg, and this slowly increased, until next day it formed a tumour equal in size to a small cocoanut. The skin over the mass was of a bluish colour, and the tumour itself felt semi-solid in character. By degrees the lump slowly grew less, and at the end of six weeks had practically disappeared. As no operative interference was called for, the nature of this swelling could not be ascertained with certainty, but from its mode of onset, and from its gradual absorption, there could be little doubt that it was formed by an extravasation of blood into the tissues round the rectus muscle.

Dr. J. D. MALCOLM said: "I have seen only one case of this kind. It occurred in a woman past the menopause. An abnormal swelling was found after strain. It was situated over the gall-bladder region, and was confidently diagnosed as something inside the peritoneal cavity. The operation showed a small cavity in the abdominal wall containing old thickened blood, and the peritoneal sac was not opened. Recovery was satisfactory after temporary drainage.

Dr. AMAND ROUTH had seen one case of hæmatoma of the abdominal wall in a woman who had for some time had a small umbilical hernia, the ring

of which suddenly gave way during a sudden effort, and hæmorrhage took place below the protruding bowel.

In the discussion on Dr. Russell Andrews' paper, Dr. CUTHBERT LOCKYER related details of a case of hæmatoma occurring during the fifth month of pregnancy. The patient was seen in March, 1908, in consultation with the late Mr. Stanley Boyd and Dr. Mitchell Bruce. Three days previously she was seized with general abdominal pain which was soon confined to the right side and back. The pain was accompanied by nausea, retching and frequency of micturition. Attacks such as this recurred several times during the next two days, and on the third day the pain and retching lasted for four hours. In the intervals between the attacks the patient felt quite well excepting for an "aching in the right side" of the abdomen. There was a tense swelling occupying the right flank, quite apart from, and independent of, the gravid uterus; it was tender and fixed. A skiagram was taken and revealed nothing. There was a trace of albumen and also granular casts in the urine. In the light of the clinical history Dr. Mitchell Bruce thought that the swelling was due to the presence of a renal calculus. Cystoscopic examination showed the bladder and ureteral orifices to be healthy, the ureteral jets were clear, feeble, and infrequent on both sides. At the operation an incision was made over the anterior aspect of the mass in the right flank, and as soon as the flat abdominal muscles were divided a large hæmatoma was discovered in the extraperitoneal connective-tissues. The latter were dissected up by the clot which tracked round to the outer aspect of the flank. No explanation could be found for such a curious lesion, but as there had been two operations (also during pregnancy) for appendicitis (in May, 1904, and in January, 1905)—*i.e.*, three years previously, it was suggested that some of the old chocolate-coloured blood which was present might have been due to the latter of those two operations.

The wound healed and the patient went to term. During the remainder of the pregnancy careful dieting was necessary owing to the persistence of albuminuria and a low percentage of urea. Labour at term was spontaneous, the child was still-born, the presentation a breech. As four of the seven cases of hæmatoma related by Dr. Russell Andrews had occurred in pregnant women, Dr. Cuthbert Lockyer raised the question of an inter-relationship between this blood lesion and the gravid state. In two cases, the first of Dr. Andrews' series and the one now referred to by Dr. Lockyer, there were many points of resemblance. In each there was a tender dull swelling in the right flank, and also albuminuria and granular casts. In each a renal lesion was diagnosed. In each the tumour was adherent to the anterior abdominal wall and old blood escaped through the abdominal incision. Finally in each case the child was born dead. In these two cases it seemed quite reasonable to infer that changes had occurred in the blood-stream, the nature of which was to be found in the co-existence of pregnancy. Schmorl and others had shown that in eclampsia pulmonary emboli containing syncytial masses have been found, and where such emboli are present local hæmorrhages result. It is evident that histological proof—*i.e.*, the demonstration of the presence of chronic (syncytial) emboli in large parietal hæmatomata, is never likely to be forthcoming, but it seems fair to assume that these lesions are yet another example of the morbid processes which can be brought about by placental products.

Dr. ANDREWS said that he thought it was possible that some cases of painful swellings of the

abdominal wall during pregnancy diagnosed as dermoids were really cases of hæmatoma of the abdominal wall.

Dr. F. J. McCANN read a short communication on a

CASE OF ABDOMINAL PREGNANCY, PROBABLY PRIMARY.

A patient, *æt.* 35, had had three children. In her fourth pregnancy there were no symptoms to suggest that it was in any way abnormal, and slight labour pains came on at the time when they were expected. These pains passed away, and there were epigastric pain, vomiting, distension of the abdomen, and before long partial intestinal obstruction. A few days later Dr. McCann was able to diagnose that the pregnancy was extra-uterine. He opened the abdomen and removed a dead, fully-developed child and the uterus, on the posterior surface of which the placenta was inserted.

Dr. McCann thought that this was a case of primary abdominal pregnancy.

Dr. JOHN PHILLIPS read a paper on

ACUTE HEPATIC TOXÆMIAS COMPLICATING PREGNANCY AND LABOUR.

In bringing the subject forward for discussion he noted that no previous consideration of this important complication of pregnancy and labour had ever taken place before this Society. He related five cases arising in just over 2,000 carefully recorded cases of labour in private practice, which presented many similar features and which could be placed in one group. Many of the symptoms were similar to those observed in acute yellow atrophy and late chloroform poisoning. These symptoms were carefully compared, and the author concluded that the disease in his cases was due to an ascending toxæmia of the bile ducts.

The PRESIDENT thought it noteworthy that only five cases of hepatic toxæmia had occurred in a total of two thousand deliveries. He judged from this fact that a special combination of morbid conditions was needed to bring about the storm. Again, the rapid fatality in two of the cases and the milder attack in those which recovered suggested the same idea of varying intensity of combination. In formulating any theory, three factors would have to be considered: (1) The changes in the liver cells associated with fatty metamorphosis; (2) the action of toxic substances ascending by way of the bile ducts from the intestine; and (3) the influence of chloroform as a determining cause. Chloroform as a "primary" cause could be put out of court, for otherwise these cases would occur more frequently, but the drug might help sometimes to precipitate an attack by encouraging acidosis. Sir Lauder Brunton had taught us that an important function of the liver was to deal with poisons entering the portal circulation from the intestinal tract, and to prevent them from passing into the general circulation. Such poisons might be in such excess as to destroy the hepatic structure and functions, as in the case of acute yellow atrophy—or the liver might be functionally inadequate to deal with these poisons, though the latter were only present in such quantities as could be easily disposed of by healthy organs. Regarded from this point of view, acute yellow atrophy was not a disease of itself, but merely represented the most severe degree of hepatic toxæmia. Time did not permit of discussion regarding the changes which took place in the hepatic cells, but physicians and pathologists were in agreement that fat storage and fat infiltration were marked in the liver as well as in other organs during pregnancy. The influence of these changes on the resisting power of the liver tissue was obvious. The President quoted two cases of

hepatic toxæmia which had occurred in his own practice, and laid stress on the fact that in both instances signs and symptoms of intestinal disturbance had manifested themselves for some days before the onset of severe disease. He agreed with Dr. John Phillips that the mischief was started by intestinal disease and spread along the line of the hepatic vessels and ducts. Fatty metamorphosis and chloroform inhalation were possibly additional factors in determining the onset and severity of the symptoms.

Dr. AMAND ROUTH thought the title of Dr. Phillips' paper might be altered to "Toxæmia in Pregnancy Affecting the Liver," for he thought true pregnancy toxæmia began in the cells of the chorionic villi and affected different secreting or glandular organs, according to the type of toxin or the condition of the patient's organs. The question of the efficiency of the anti-toxins formed to counteract the physiological toxins had also to be considered. Possibly the anti-toxins, if in excess, might cause a true toxæmia. Most of Dr. Phillips' cases were associated with *Bacillus coli* cystitis, and in such cases the liver troubles might be due to ascending intestinal infection by the same organism or by toxins derived from those bacilli. If so, those cases were not due to true "toxæmia of pregnancy," but, directly or indirectly, were due to infection.

Dr. WALTER GRIFFITH, Dr. EARDLEY HOLLAND and Dr. HERBERT WILLIAMSON also discussed the paper.

Dr. JOHN PHILLIPS, in reply, said: I am much obliged for Dr. Walter Griffith's kind words. Dr. Routh finds great difficulty in defining "toxæmia," and I think that is the general feeling. I quite agree with Dr. Williamson that the five cases described are capable of sub-division, and that case 2 was in all probability a case of late chloroform poisoning. The term "ascending toxæmia" was given to those cases for want of a better term.

SECTION OF SURGERY.

At a special meeting of the Section to be held on Wednesday, July 12th, at 5 p.m., Dr. Fred H. Albee, of New York, will give a cinematograph demonstration of his methods and *technique* of bone surgery, including bone grafts for Pott's disease, inlay grafts for fracture of long bones, peg grafts for fracture of the neck of the femur, etc.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, APRIL 14TH, 1916.

The President, W. A. WINTER, M.D., F.R.C.P.I., in the Chair.

THE DISTRIBUTION OF CEREBRO-SPINAL FEVER IN A MILITARY CAMP.

Dr. NESBITT read a note on the above, which was published in THE MEDICAL PRESS AND CIRCULAR, May 24th, 1916, page 469.

Exhibit.—Dr. Kirkpatrick exhibited two old London Bills of Mortality for the years 1685 and 1686.

THE WINTER OF 1915-16.

Sir JOHN MOORE, D.P.H., read a paper, illustrated by lantern slides and by copious statistics, bearing on many unusual features in the weather of the past winter. It had been characterised by a very cold November; a stormy, wet, and open

December; a stormy and exceptionally warm January; a cold, windy, and rainy February; and a very cold and snowy March.

The rainfall of the six months ended March 31st, 1916, was, in Dublin, 21.711 inches on 120 days, compared with an average of 13.970 inches on 102 days. In other words, the rainfall exceeded the average by 55 per cent., and the rain-days by nearly 20 per cent. The large rainfall of November was accounted for by the downpour which accompanied the tempest of the 11th and 12th, during which 2.537 inches fell in Dublin. The warm January was rainy in the south and west of Ireland, but Dublin received only 1.398 inches of rain compared with an average of 2.210 inches, and the month was dry in the east and south-east of England. The copious precipitation in March came with cold N.E. winds, and consisted largely of hail and snow.

The key to the conditions indicated as characterising the past winter was to be found in:—

- (1) The distribution of atmospheric pressure over the Atlantic and Western Europe.
- (2) The resulting prevalent winds: their force or weakness.
- (3) The presence in the atmosphere of an undue quantity of matter in the form of dust—chemical or otherwise.

The harmful effect on human life of the bitter cold of February and March was shown by the increased mortality from diseases of the respiratory system, and especially from pneumonia in Dublin during those months as compared with January. Fourteen weeks of the year, 1916, were completed on April 8th. In the first seven weeks, the registered deaths from pneumonia numbered 70, and those from other diseases of the organs of respiration 113. In the second seven weeks the corresponding numbers were 133 and 235 respectively. In the case of pneumonia the increase was 90 per cent., in that of other respiratory affections it was 108 per cent.

SPECIAL REPORTS.

VISIT OF FRENCH PROFESSORS TO EDINBURGH.

RECEPTION BY THE UNIVERSITY OF EDINBURGH ON JUNE 8th.

ADDRESS OF WELCOME BY PROFESSOR SIR THOMAS R. FRASER, M.D. Dub., F.R.C.P.ED.,

Hon. Physician to His Majesty the King in Scotland.

GENTLEMEN,—In your name I have the pleasant task of very cordially welcoming to the University the distinguished delegates of our gallant ally, France. We are proud to receive them. We are gratified that they represent so many of the higher educational and academic institutions of their country—not of Paris only, but also of Lyons, Grenoble, Clermont, Montpellier, Nancy, and Poitiers.

The visit recalls the specially close relations of friendship and co-operation that have existed between France and Scotland for many centuries, and have on more than one occasion been cemented with blood. The desire that it should be continued and maintained has been shown by the existence of the Franco-Scottish Society, which I understand will show the reality of its friendship by co-operation in the general desire to aid our visitors in acquiring information regarding Edinburgh and Scotland. Before the present one, there has, however, been no formal or official visitation since April, 1884,

when with almost unprecedented success the University celebrated the tercentenary of its foundation.

It is my good fortune to be one of the few survivors in the Senatus of this epoch-making event. We then received, through their numerous representatives, the congratulations of practically every civilised nation and educational institution in the world. We regret that the distorted arrogance of some of these nations, and even of their most educated classes, has disappointed us in the full expectations of friendship then originated. We all the more rejoice that the bonds of union between many of these nations, including France, have been unbroken and, indeed, drawn closer by the momentous events of the last few months. At our tercentenary, the same learned bodies who have to-day honoured us were represented, and from France many men whose names are historic to the annals of philosophy and science. Among them I may be permitted to mention Mègierès, Perrot, D'Abbadie, Gréard, Chauveau, Caro, De Lesseps and Pasteur. In the interval of 32 years that has elapsed since our tercentenary celebrations the University has made much progress. In 1884, the number of professors was 46, there are now 59; in the former year the number of lecturers was only 3, to-day it is 94. Practical instruction and research were, in 1884, scarcely recognised or deemed a part of higher education. They were most meagrely provided for. Now the great part of our much enlarged accommodation is occupied by well-equipped laboratories for these purposes, which I hope our distinguished visitors will have an opportunity of inspecting. It is unfortunately the case, however, that the full life and activities of the University cannot at present be exhibited. The requirements of the devastating war in which, with our gallant Allies, we are engaged against a ruthless and unchivalrous enemy—the patriotism of our alumni and teachers—have depleted our numbers so that, while our Matriculated Students in 1913-14 numbered 3,283, their number has fallen in the present session to 1,797.

This number will next session be further reduced, as all eligible students will be required to give their services to the State, except those of the fourth and fifth years in the Faculty of Medicine. At the same time the University has given up some of its buildings for war purposes; and in several of its departments, such as those of engineering, natural philosophy and physiology, professors and students are undertaking much research work for the Government in physical and medical subjects.

Those who have joined the active services will take their part in defending their country and kinsfolk, and in preserving the liberties and humane conceptions and international morality of civilised mankind. Before the recent passage of the General Service Act, upwards of 4,500 graduates and students had joined the Services—or 1,217 more than the total number of matriculated students (both men and women) in the Session 1913-14. Of these at least 170 have been killed in action or otherwise in war service, 126 have been wounded, 2 are missing and 8 are prisoners. They have acquitted themselves well, as military honours and decorations have been conferred on upwards of 77, while other 90 have been mentioned in dispatches.

We do not as yet know how many others of them have perished in the destructive naval victory of Horn Reef. We do know, however, that other two members of the University have met with an untimely end in the deplorable catastrophe that overtook H.M.S. *Hampshire* recently—namely, Lord Kitchener and Sir Hay Donaldson, a member of his Staff.

The circumstances of Lord Kitchener's death may recall those of his friend and military guide and teacher, Lord Roberts, also an Honorary Graduate of this University. The latter also was the greatest British General of his time—the untiring and too often unappreciated prophet of the dangers of unpreparedness—and he unexpectedly perished in France while engaged in a mission to the British and Indian troops.

Lord Kitchener's death adds to the sorrow and Academic gloom still remaining after the death of our late greatly distinguished principal, Sir Wm. Turner. We have now to lament the loss of our Lord Rector. These bereavements, as our guests will understand, have led to some curtailment in the expression of our hospitality, but I am sure not in the warmth and cordiality of our welcome. We lament Lord Kitchener's death with the whole nation, with our Allies, and all the neutral powers, and with all of our enemies who yet retain the attributes of chivalry and humanity. His death I feel sure will not in the least degree lessen the unalterable determination of this Empire and of its faithful Allies to continue unflinchingly the task which has been impressed on them of curbing the arrogant assumptions and the menace to liberty and civilisation of our inhuman Germanic enemy. The few hours that have separated the destruction of the *Hampshire* from the naval engagement in the North Sea seems to render it almost one of its episodes. We may congratulate ourselves that this naval engagement will restrict even more closely than before the predatory aims of the German Navy. It has raised still higher the ardent desire of our gallant seamen to encounter the ships of the enemy whenever they leave the protection of their carefully prepared appliances of destruction, and refrain from fleeing to this protection when no longer in overwhelming force.

We are determined also to gain a decisive victory on land. We are fortunate in the most efficient co-operation of the gallant nation so well represented by our guests, as well as in that of Russia and Italy and Belgium. We are confident that the bravery and martial spirit displayed in the East as well as in the West will lead to that result. Our admiration is great for the valour and resource of our French Ally in the unprecedented battle of Verdun.

After the conclusion of such a victorious peace, we have to recollect that we shall enter on another war—a war of commercial and manufacturing industry and rivalry, upon which the fate of nations will largely depend.

Upon us, who are the leaders and representatives, will fall the patriotic duty of initiating and supplying the required education. I apprehend that our educational systems and methods will require remodelling, so as to increase the facilities for advanced instruction in a wider range of the community than is now overtaken. A great lesson which the war has expounded is that expansion is required not only in general education, but especially in science and technology, in finance and commerce and modern languages, and in the physical training of the body, and perhaps also in mental and moral discipline.

In the name of the University, I would again most cordially welcome our guests and place at their disposal all the means that we possess for furthering the objects of their visit to this University and to the Capital of Scotland.

DR. JONATHAN BRUMWELL, M.D., of Barden, Victoria Avenue, Shanklin, left £17,122.

MR. GEORGE GRAY ANDERSON, of Wimbledon, left £50 to the Scottish Hospital in London.

OBITUARY.

DR. W. W. WEBBER, L.R.C.P.ED., M.R.C.S.ENG., CREWKERNE.

THE death has occurred at Crewkerne of the oldest medical practitioner in the town—Dr. William Woolmington Webber. Dr. Webber was a Crewkerne School Exhibitioner in 1873. He received his medical training at St. Thomas's Hospital, and qualified M.R.C.S.Eng. in 1880, and L.R.C.P.Edin. in 1882. He then became associated with the late Dr. Cox, of Crewkerne, and, on the death of that gentleman many years ago, succeeded to his practice. He continued in active work up to within a couple of days of his death. Dr. Webber was formerly associated as a medical man with a good many of the Friendly Societies in the district, and, as Poor-law Medical Officer, he was well known throughout the countryside. He was Medical Officer of the Crewkerne Urban District Council and Surgeon to Crewkerne Hospital. The deceased, who never married, was about 52 years of age.

DR. F. J. WADD, M.B., M.R.C.S., RICHMOND.

DR. FREDERICK JOHN WADD died at Richmond, Surrey, on June 12th, at the age of 71. Deceased, who received his medical training at St. Thomas's Hospital, qualified M.R.C.S.Eng. and L.S.A.Lond. in 1866, and in the same year proceeded to the M.B., C.M. of Aberdeen. He was Honorary Surgeon to the Richmond Hospital, and was for many years the family physician to the Duke and Duchess of Teck when they resided at White Lodge. He attended the Queen at the birth of the Prince of Wales. Dr. Wadd took an active part in local affairs, and served for twenty-two years as a member of the Richmond Town Council, occupying the position of chairman of the Health Committee for seventeen years.

DR. W. ANDERTON, F.R.C.S., ORMSKIRK.

THE death occurred on June 12th of Dr. W. Anderton, of Ormskirk, after a sharp attack of pneumonia. He had been ill a week, but no serious complications were feared until almost the last. His death removes one of the oldest and best-known practitioners in South-West Lancashire.

Dr. Anderton was 68 years of age. Educated at Liverpool and Edinburgh, he qualified L.R.C.P. and S.Edin. in 1872, M.R.C.P. and F.R.C.S. in 1881. He was the medical officer of health for the Ormskirk Urban District Council for over 40 years, holding the position up to his death. He had also been medical officer of health and public vaccinator for the Ormskirk Union for over 40 years, retiring in 1913; but on Dr. John Young, his successor, joining the colours, he resumed again. He was also senior surgeon to the Ormskirk Dispensary and Cottage Hospital, and visiting physician to the Ormskirk and Lathom and Burscough Joint Hospital Board. He was a member of the Liverpool Medical Institution, and was held in the highest esteem by his professional brethren.

He leaves a widow, two sons, and two daughters.

At a conference on sanitary administration under war conditions held in London, on June 9th, the Lord Mayor presented the Henry Saxon Snell prize of fifty guineas and the silver medal of the institute to Dr. William Hanna, assistant port medical officer, Liverpool, for an essay on suggestions for improving the sanitary arrangements and appliances on board ships. The Lord Mayor said it gave him special pleasure to present the prize to a competitor from his native town.

MRS. HANNAH GREAVES, of Southport, Lancs, left £200 to the Middleton Cottage Hospital.

DEPUTY SURG.-GENERAL EUGENE FRANCIS O'LEARY, M.D. (retired), of Sidmouth, left £18,627.

MEDICAL NEWS IN BRIEF.

Maternity and Child Welfare.

DR. F. G. HAWORTH, Medical Officer of Health for Darwen, in a report on the subject of maternity and child welfare, says:—"I would recommend that a sub-committee be appointed from the members of the Town Council, and a meeting be held, composed of this sub-committee and the medical men practising in the town, to discuss the particular lines on which this treatment can be carried out, and to draw up regulations of the times at which the doctors can meet their patients. The point of venue might be at the doctor's surgery or at the school clinic—the former might for many reasons be more convenient, as then the patients would receive any medicine required at the time. I would make it incumbent on all mothers with babies under twelve months old to attend the Mothers' Club, where they could consult their own doctors on all light ailments from which their babies may be suffering at that particular time; these meetings to be held weekly instead of fortnightly, as is at present the case. This would bring the babies more frequently under the notice of the doctor, and there would not be the danger of a disease running too long before the case was seen by a medical man. It would *ipso facto* increase the number of members of the club and *pro rata* increase the benefits, the doctors to attend this club in rotation and the work to be done under the supervision of the Medical Officer of Health. Any mother desiring information or advice on all matters pertaining to the period before childbirth, and also on any other period, may do so from her own doctor at the meeting of the Mothers' Club. Any doctor not keeping his appointment at the club a certain number of times will be asked to withdraw his services from this work. In the case of children from twelve months old up to the school age—viz., five years—to attend at his or her doctor's surgery for treatment. After this time the school children come under the care of the School Medical Officer until they reach the age when they become insured persons. With the exception of very minor ailments, they will also be attended by their own doctor during the school period."

Doctor as an Army Absentee.

IN the Oban Sheriff Court, on June 9th, before Sheriff-substitute Wallace, John Cameron MacCallum, M.B., Ch.B., Muckairn Manse, Taynuilt, recently Executive Tuberculosis Officer and Assistant Medical Officer for the county of Argyll, appeared on a charge of having been deemed to have been enlisted and transferred to the Army Reserve under the Military Service Act, 1916, and having failed to report himself at Stirling Castle on 30th ult. in accordance with the requirements of notice served on him. The accused pleaded not guilty, and in reply to the Sheriff-substitute admitted a breach of the Statute, but in view of the conscientious objections he held to participating in war service in any capacity he maintained he could tender no other plea than that of not guilty. He acknowledged that he had not received a certificate of exemption as a conscientious objector, although he had applied for one. Formal evidence having been led by the Procurator Fiscal, the Sheriff-substitute convicted accused and sentenced him to pay a fine of £2 or one week's imprisonment. On leaving the dock Dr. MacCallum was taken into custody by a military escort.

Municipal Crèches for Birmingham.

THE question of providing municipal crèches in Birmingham was brought before the Public Health and Housing Committee of the City Council, on June 9th, by the Lord Mayor (Alderman Neville Chamberlain), and it was decided to make inquiries as to the need for and the possibility of putting a scheme in operation. The committee are considering this matter purely as a war-time measure, for they are not at all favourable to the idea of maintaining crèches in ordinary times and unnecessarily relieving mothers of responsibilities they ought to bear. But at present they have to face the fact that mothers have gone,

and are going, into munition factories where their services are urgently needed, and it is felt that however much they may try to avoid it their children are not being as well looked after in their absence as is desirable. The committee have been given power to start a crèche as an experiment if the inquiries are satisfactory, but the Lord Mayor is of opinion that the evidence will show eight or ten crèches will be required to meet the needs of the whole of the city. He also suggested to the committee that these crèches should be established in open districts or gardens, so that the children will get plenty of fresh air.

Bournemouth Consumption Sanatorium.

THE Earl of Eldon presided over the annual meeting of the Royal National Sanatorium for Consumption and Diseases of the Chest, Bournemouth, held on June 14th. The Committee of Management in their report stated that the good work of the Institution had been maintained. The total number of patients treated last year was 506. The numbers discharged were 186 men and 220 women; 14 patients had died, and 86 were still under treatment. The patients came from all parts of England and Scotland. There were also seven Belgian refugees. There was again an excess of income over expenditure, and the substantial balance was due largely to the exceptional amount received from legacies and the great effort made to effect economy. Only the most urgent repairs had been carried out, and this would mean a considerable outlay at the end of the war. In spite of every care there had been an increase of £500 over the expenditure of the previous year, and there had been a further decrease of £150 in the annual subscriptions.

Lord Eustace Cecil, in moving the adoption of the report, said that the institution did a great deal of good and was carefully administered. The cost per week per patient had increased considerably.

The report was adopted.

Commissions for Home Service.

It is stated that the War Office have decided to grant commissions in the Royal Army Medical Corps to doctors between 45 and 55 years of age volunteering for whole time general service in the United Kingdom. This will allow the release of younger men for active service abroad.

Council of the Royal College of Surgeons.

THE annual election to the Council of the Royal College of Surgeons will take place on July 6th. There are four vacancies, and the following is a list of the candidates:—W. F. Haslam, Birmingham; T. H. Openshaw, London Hospital; Raymond Johnson, University College Hospital; John Murray, Middlesex Hospital; V. W. Low, St. Mary's Hospital; H. S. Pendlebury, St. Mary's Hospital; and F. J. Steward, Guy's Hospital.

Carlisle Death Rate.

At the monthly meeting of the Carlisle City Council on June 14th, the decreasing birth-rate and increasing death-rate in the city were matters of comment by Mr. R. Dalton during some observations on the annual report of the Medical Officer of Health. Mr. Dalton also pointed out that the rate of infant mortality, which in 1915 was 144.3 per 1,000, was the eighth highest record during the last fifty years. That, he said, was rather remarkable in view of the fact of the enormous sums spent on health visitation.

Wellington's Medical "Chief."

At a meeting of the Aberdeen University Court on June 13th, Principal Sir George Adam Smith, who presided, said that in the end of April he received a letter from Sir J. R. D. M'Gregor, Bart., intimating his willingness to convey to the University of Aberdeen a painting of the quadrangle of Marischal College, as it was before the recent additions, and including the obelisk which used to stand in the quadrangle, and which was now in Duthie Park. He said to Sir James M'Gregor that he had no doubt that the University Court would gladly receive that painting. Now that it had come, he felt more grateful than ever to him for

sending it; and they accepted it for their collection of historic and other paintings with gratitude. (Applause.) They would empower him to write Sir James M'Gregor, expressing the thanks of the whole University for his valuable and interesting gift, as a memorial of one of the most illustrious medical graduates which his University ever had—Sir James M'Gregor, chief of the Duke of Wellington's medical staff in the wars in the beginning of the last century, and the man who thoroughly reformed the administration of the military medical service in Great Britain. The gift came to them at the present time with very great appropriateness. (Applause.)

Shoreditch Guardian loses Seat through Child's Illness.

As a result of one of his children being taken ill with an infectious disease, Mr. C. E. Taylor has lost his seat on the Shoreditch Board of Guardians. Because no accommodation was available at the Metropolitan Asylums Board Fever Hospital the child was removed to the Infirmary. Thereupon the Guardians sought counsel's opinion, which was that Mr. Taylor had lost his right to sit upon the Board. The Guardians on June 15th decided by six votes to two to declare the seat vacant.

"I shall be here. I shall come. Don't worry; you have had some rows here in the past, and take it from me that you will have some in the future," Mr. Taylor declared, as he left the room.

British and German Food Prices.

ACCORDING to the *Board of Trade Gazette* of June 16th, retail prices of food in the United Kingdom on June 1st were higher by 2½ per cent. than on May 1st. British and imported meat advanced about 8 and 9 per cent. respectively on the average, or about 3d. to 1d. per lb. As compared with June 1st, 1915, the retail prices at the opening of the present month showed an average increase of 20 per cent., potatoes and granulated sugar rising by 60 and 50 per cent. respectively. The average increase in the retail prices of food over the whole country since the beginning of the war may be put at 59 per cent., or 53 per cent. if the increase in the duties on tea and sugar is deducted. The average increase in the cost of living of the working classes, taking food, rent, clothing, fuel and light, etc., into consideration, between July, 1914, and the present time, is about 40 per cent., disregarding increased taxation and assuming that the standard of living has not been modified in view of war conditions.

In Berlin in April a further rise of nearly 10 per cent. was recorded in the general level of food prices, the index number of the total rise since July, 1914, being thus brought up to close on 120 per cent.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

LETTERS TO THE EDITOR and Original Papers intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of bona fides. These should be addressed to the Editor at the Offices of this Journal: if in Ireland, to the Dublin Office, 29 Nassau Street; from other parts of the United Kingdom, these should be addressed to the London Office, 8 Henrietta Street, Strand.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

WORKMEN'S COMPENSATION ACT, 1906.

THE Secretary of State for the Home Department gives notice that, in consequence of the resignation of Dr. J. W. Batterham, one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 50 (Eastbourne, Hastings and Rye) the appointment held by him will be vacant as from the 18th inst. Applications for the post should be addressed to the Private Secretary, Home Office, Whitehall, London, and should reach him not later than July 1st.

LEVEN (Hulme).—We have made a note of your view. You will find the matter discussed by "Sinapis" in our present issue.

33-IN. ADDER.

AN abnormally sized specimen of the adder, measuring 33 in., was killed by Mr. Neil Baxter, at Ardura, and it is believed to be the largest every found in Mull.

TIGHT MONEY!

MEDICAL examiners for the United States Marine Corps state that men are taller in the morning than in the evening. Nevertheless, some men, after they have been out for the evening, find themselves shorter in the morning.—*The Globe*.

ANOTHER INDIGNITY!

A COLCHESTER woman has been engaged to act as superintendent of a number of conscientious objectors who are learning to do work on the land at an Essex farm.

E. M. J. (London).—We have received the book and noted with interest its contents.

SHAKESPEARE'S CRADLE?

AN Elizabethan oak cradle marked in contemporary carving, "W. S., 1564" (initials of William Shakespeare and date of his birth), will shortly be sold at Sotheby's. The cradle came originally from Bidford, some fifteen miles from Stratford.

SOUTH AFRICAN MILITARY HOSPITAL.

THE South African Military Hospital, which is being erected on a site in Richmond Park, granted by the King, is now practically completed. Subscribers to the South African Hospital and Comforts Fund inspected the hospital on June 17th.

S. M. (Weymouth).—He will not be drawn into controversy.

GERMAN STUDENTS AND THE ARMY.

FIFTY-FIVE thousand German students are now enrolled in the German Army, according to an official return issued in Berlin. The number of male students actually attending lectures at German Universities is thus only 2,400, all of whom are physically unfit for military service of any kind.

BERLIN'S DECREASING POPULATION.

SINCE the beginning of the war the population of Berlin has decreased by 400,000.

"CHILDREN'S SALON" AND HOSPITALS.

AT the 26th annual competitions of members of the "Children's Salon" on June 17th, it was stated that 433 fairy godmothers had undertaken to write to or send gifts to some poor child. The "Salon" has founded eleven cots in the various London hospitals.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JUNE 21ST.

ROYAL METEOROLOGICAL SOCIETY (70 Victoria Street, Westminster, S.W.).—4.30 p.m.: Paper—Lieutenant E. H. Chapman, R.E.: The Relation Between Atmospheric Pressure and Rain-fall at a Single Station.

THURSDAY, JUNE 22ND.

ROYAL SOCIETY (Burlington House, London, W.).—4.30 p.m.: Croonian Lecture—Prof. S. J. Hicksyn: Evolution and Symmetry in the Order of Sea-pens.

FRIDAY, JUNE 23RD.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8.15 p.m.: Cavendish Lecture—Sir John Bland-Sutton: The Fate of Patients who have had Stones removed from the Kidney.

Vacancies.

OMAGH.—Temporary Medical Officer. Salary £4 4s. per week.

Apply to John Patrick, M.B., Res. Med. Supt. (See advt.) Derbyshire Royal Infirmary, Derby.—House Surgeon. Salary £200 per annum, with board, residence, etc. Applications to E. Forster, Secretary.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Lady House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38, Barton Arcade, Manchester.

Bury Infirmary.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing. Applications to the Hon. Secretary, Infirmary, Bury, Lancs.

West Riding Yorkshire.—Middleton-in-Wharfedale Sanatorium, nr. Ilkley.—Lady Assistant Medical Officer. Salary £300 annum. Applications to Francis Alvey Darwin, Clerk of the County Council, County Hall, Wakefield.

Great Yarmouth Hospital.—House Surgeon. Salary £200 per annum, with board, lodging, and washing. Applications to Richard F. E. Ferrier, Hon. Secretary, 16, South Quay, Great Yarmouth.

Huddersfield Royal Infirmary.—Senior House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to Mr. J. Bate, Secretary, Royal Infirmary, Huddersfield.

The Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £150 per annum, with board, residence, and washing. Applications to the Secretary, at the Hospital.

London Temperance Hospital, Hampstead Road, N.W.—Assistant Resident Medical Officer. Salary £120 per annum, with residence, board, and laundry. Applications to the Secretary.

Births.

DICK.—On June 11th, at Tadworth, Surrey, the wife of F. A. Dick, M.B., Lieutenant, R.A.M.C. (T.), of a daughter.

HAY.—On June 17th, at 14, Vicarage Gardens, Kensington, W., the wife of Dr. K. R. Hay—a daughter.

HENDERSON.—On May 18th, at Fairmont Heights, Eugene, Oregon, to Dr. and Mrs. McClelland Henderson—a son (still-born).

JUSTICE.—On June 15th, at 55, Palace Gardens Terrace, W., the wife of Major W. A. Justice, I.M.S., Madras, of a son.

PAYNE.—On June 12th, at Lansdowne House, Alton, Hants, the wife of O. V. Payne, M.B., B.C., of a son (still-born).

POWELL.—On June 12th, at Harrogate, the wife of Major Jack Powell, R.A.M.C., Cairo—a son.

RODGERS.—On June 13th, at Hollin's Lane, Winwick, Warrington, the wife of Fred Rodgers, M.D., Major, R.A.M.C. (temporary), of a son.

SIEGWICK.—On June 12th, at "Fircot," Ashby Parva, Lutterworth, the wife of Major Siegwick, R.A.M.C.—a daughter.

SPEIRS.—On June 13th, at 232, Old Kent Road, S.E., the wife of T. Orr Speirs, M.D. (Glasg.)—a son.

THURLOW.—On June 10th, at Easdale, Frant Road, Tunbridge Wells, to Dr. and Mrs. Basil L. Thurlow—a daughter.

WRAITH.—On June 11th, 1916, at Gwynant, Hampton Park, Hereford, the wife of Oswald S. Wraith, M.D., F.R.C.S.E., of a son.

Marriages.

ADAMSON—TURNBULL.—On June 15th, at St. Mary's, Harrow-on-the-Hill, by the Rev. A. M. Bashford, J. D. Adamson, Lieut., R.A.M.C., to Edna Turnbull, eldest daughter of Mr. and Mrs. J. H. Turnbull, of Winnipeg, Canada.

COX—COATE.—On June 14th, at St. Matthew's Church, Luton, Beds., William Joseph Cox, M.B., Ch.B., D.P.H., elder son of the late Joseph Cox, Esq., of Rotherham, Yorks, to Frances Henrietta Coate, youngest daughter of the Rev. Harry and Mrs. Coate, of St. Matthew's Vicarage, Luton.

FRASER—BAILEY.—On June 13th, at Golden Hill Parish Church, Captain Forbes Fraser, F.R.C.S., of Bath, to Agnes Mary, daughter of the Rev. G. R. Bailey, Vicar of Golden Hill and Rural Dean of Newcastle, and Mrs. Bailey.

KILNER—SIMPSON.—On June 10th, at St. Leonard's Church, Haringey, Lieut. Henry Goff Kilner, R.A.M.C., second son of Dr. and Mrs. Chas. Scott Kilner, of Bury St. Edmunds, to Mabel Olive, only daughter of Mr. and Mrs. R. T. Simpson, of Horsecroft, Bury St. Edmunds.

LINK—FOWLER.—On June 17th, at Iford, Captain O. C. Link, M.B., B.S., R.A.M.C., second son of Mr. and Mrs. G. D. Link, of 34, Mansfield Road, Iford, to Grace Madeline, eldest daughter of the late W. Fowler and Mrs. Fowler, Iford.

ORR EWING—SHAW.—On June 15th, at St. Mary's Church, Wimbledon, Capt. Hugh J. Orr Ewing, R.A.M.C., only son of the late John Orr Ewing and Mrs. Orr Ewing, of Weston-super-Mare, to Muriel Isabel, eldest daughter of Mr. and Mrs. Ernest E. Shaw, of Wimbledon.

PUNCH—SHORROCKS.—On June 3rd, at Holy Trinity Church, Northwood, Middlesex, Dr. Arthur Lisle Punch, youngest son of J. J. Punch, Esq., of Bedford Park, to Dorothy, youngest daughter of Mrs. Shorrocks, of The Glen, Northwood.

TINDAL-ROBERTSON—MARSDEN.—On June 14th, in London, Percy Tindal-Robertson, of the Albany, W., and Lincoln's Inn, to Edith Maude Marsden, M.B., Ch.B., of Oakenrod, Rochdale.

Deaths.

FOSTER.—On June 14th, at 10, St. George's Road, Eccleston Square, S.W., Joseph Foster, M.D., in his 76th year.

FREER.—On June 10th, at The Limes, Stourbridge, Alfred Freer, J.P., Co. Worc., Surgeon, son of the late William Henry Freer, Surgeon, Green Close, aged 87.

WADD.—On June 12th, at "Burvale," Richmond, Surrey, Frederick John Wadd, M.B., M.R.C.S., Honorary Surgeon to the Richmond Royal Hospital, aged 71 years.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

Vol. CLII.

WEDNESDAY, JUNE 28, 1916.

No. 26.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

If any of my readers had been in **State Medical Service.** doubt about the reality of the threat to inaugurate a State medical service, the columns of the lay press during the last fourteen days would surely have convinced the most purblind. So unanimous has been the note, so mellifluous the tone, so persuasive the argument, that one is forced to the conclusion that the chorus has not only been inspired, but well trained. There is not, as I have before pointed out, anything intrinsically evil in a State medical service; there is, indeed, theoretically much to be said in its favour. It is quite obvious that there would shortly have to be some co-ordination of such medical services as are actually rendered to the State, and when we consider those which are authoritatively and quite reasonably projected, the case for a re-shuffling of the cards becomes overwhelming and insistent. The importance of the doctor to the community is now being recognised, and the community through its astuter representatives is busily engaged in partly flattering, partly depreciating, and wholly mesmerising the doctor into a mental condition of complete blindness to his own interests.

An Annual Report. THE most recent sardonic touch and, as coming from a member of the profession, superficially one of the most telling, was elaborated in the Isle of Wight. The annual report which Dr. J. P. Walker, the M.O.H. to the Island, recently presented to his authority, has been the subject of much ribald comment in the daily press, which, as the following extract will show, was by no means unprovoked. Says Dr. J. P. Walker: "Medical success is not necessarily dependent upon a doctor's skill and knowledge; it depends upon much besides—for example, the size of his house, the luxuriance of his motor-car, the charm and ability of the doctor's wife—all these influence his worldly success. But should he venture to criticise those who employ him! How fares he, for example, should he tell his best-paying patient there is nothing really the matter with her, that she needs work, and that employment would rob her of all her fancied ailments? Should he tell his chief magnate that the death-rate from consumption is due to his germ-breeding cottages, how would he fare?"

THIS can hardly be described as creditable either in manner or matter. The manner is relatively unimportant, but it affords a very good example of the "sloppiness" in medical writing which Dr. Mercier properly deplores. And as to the matter, surely a Medical Officer of Health could find something more worthy of a place in his annual report than this cheap cynicism at the cost of his own cloth. In so far as there is truth in these impertinent and ill-timed reflections, that truth is not only a commonplace of medical practice, it is a commonplace of human nature. Lack of the moral courage to endanger one's livelihood is by no means confined to medical men, who are, indeed, on the whole, far more courageous than men in most other callings; but they prefer as a rule to combine their courage with a virtue which does not seem to be very familiar to Dr. J. P. Walker, namely, the exercise of tact. When there are important matters to occupy men's minds, it is a great pity that such sorry stuff as this should find its way into the considered report of a responsible medical officer. If it is worthy of publication at all, the "Daily Mail" in the silly season is its proper place.

The Birth-rate Commission. UNDER the title of "The Declining Birth-Rate: Its Causes and Effects," the National Birth-Rate Commission has issued a report—obviously *pour rire*. In a notice on the cover, the inquiry is called "exhaustive." If this is a suitable adjective to apply to the investigation, it is singularly inapplicable to the conclusions, which are for the most part purely platitudinarian; and where they venture outside that sacred area they are unsupported, insupportable, and almost certainly false. A glance at the names of those constituting the committee is sufficient to explain a good deal. There figure Bishop Boyd Carpenter, who is 75; Dean Inge, who is deaf; Sir John Gorst, who is dead, and the Duchess of Marlborough. There are, of course, a great many other names, among which I count six clerics, about thirteen doctors, of whom, suitably enough, four are women, or, if you include Dr. Saleeby, five. Very few of the total, even among the doctors, appear to have any special knowledge which

would enable them to contribute much of value to a very important and topically pressing question.

THE Commission gravely assure us that it considers the following propositions duly established:—

Its Findings.

1. That the birth-rate has declined to the extent of approximately one-third within the last 35 years.

2. That this decline is not, to any important extent, due to alterations in the marriage rate, to a rise of the mean age at marriage, or to other causes diminishing the proportion of married women of fertile age in the population.

3. That this decline, although general, has not been uniformly distributed over all sections of the community.

4. That on the whole the decline has been more marked in the more prosperous classes.

5. That the greater incidence of infant mortality upon the less prosperous classes does not reduce their effective fertility to the level of that of the wealthier classes.

From this it is evident that when you have assembled a number of clerics, "some" Duchess, and a few lesser members of the peerage, you will arrive at conclusions, sociological and physiological, which are both novel and epoch-making. But surely the Commission ought to have begun by informing us that births are the result of the conjunction of the two sexes. That is another proposition which may be said to be "duly established."

It is characteristic of a mixed committee of this kind that it should

Its Evasions.

evade the real issues which lie beneath the surface of the question of a declining birth-rate. It is quite in keeping that it should confine itself to the superficial and avoid the essential by informing us that in some women sterility is quite unavoidable, that in others sterility or relative infecundity is the result of design, and then to branch off into a fruitless discussion as to whether limitation of families is, or is not, moral or religious, or patriotic, or whatever obscuring adjective may be selected. The limitation of the family is an individual matter which each couple will always decide for itself; and if it decides for limitation, not all the religious diatribes nor all the moral musings, nor all the patriotic preachings will have the slightest effect upon the practice.

Higher Education.

THE Commission appears timidly to have ventured upon the fringe of the really important issues, but even here it is superficial. It opines that (7) "There is no reason to believe that the higher education of women (whatever its indirect results upon the birth-rate may be) has any important effect in diminishing their physiological aptitude to bear children." This is pure nonsense. There is, on the contrary, every reason to believe that the so-called higher education of women conduces to sterility, and that, short of actual sterility, it is very apt to lead to the birth of unsatisfactory

children. The theoretical grounds in support of this last view are overwhelming, and the few facts which tell against it are negligible. But, as I have said, this is only the fringe of the really important issues.

Evasions.

THE words "whatever its indirect results upon the birth-rate may be," show that even in this matter of the "higher education" the report purposely avoids the kernel of the question. It did not require a commission to lecture us on the morality of the intentional limitation of families, or upon such of the causes of sterility in women as may be found accurately, but discreetly, set forth in Dr. Somebody's "Advice to Mothers." If it was to throw any light upon the problem of the declining birth-rate it should have been most searching in its inquiry into those indirect causes to which it is so lady-like in turning a blind eye. As a leading article in the *Times* properly points out, "no reference is made to the increasing prevalence of excessive stature among women and the modern addiction of girls to violent sports and exercises, and the possible connection of these things with natural fecundity."

Omissions.

AND these are not the only changes which have taken place in what the Americans call the "make-up" of women during the period of thirty-five years which has witnessed so decided a decline in the birth-rate. It is during those years that we have assisted at the rise of the suffrage movement, in itself mildly, perhaps, but certainly, inimical to fertility, and its offshoot the anti-man movement which is quite openly opposed to marriage and childbearing. Another ugly phenomenon which may, or may not, have a direct relation with these movements, is the undoubted and deplorable spread of the disgusting and degrading practice of lesbianism, a practice which, when rife in a community, must, of course, have a direct immediate and enormous influence in restricting the birth-rate. Every medical man of experience knows perfectly well that in the very classes in which the decline is most conspicuous this vice is most widely disseminated. To leave these and similar facts out of consideration in investigating the question of the birth-rate is characteristically British, hypocritical and ostrich-like. This omission alone is sufficient to rob this otherwise stupid report of any value whatever.

New Tests for Syphilis.

WE published last week an article from the pen of Dr. C. D. Gray, of Portland, Maine, an interesting article on "A Urinary Test for Syphilis and Its Comparison with the Wassermann Reaction." We are certainly in need of a clinical method of testing for the presence of the *Treponema pallidum*, and if the results of Dr. Gray's investigations should be confirmed by other observers, his simple ingenuity will entitle him to the gratitude of future generations of clinicians. This week we have pleasure in publishing the details of a new test which has been

devised by Mr. J. R. McDonagh, whose work in connection with salvarsan is now so well known. Mr. McDonagh's test, it will be seen, is a blood-test; it has that in common with Wassermann's over which, however, it has the advantages of being much less complicated and much more accurate. It will be a satisfaction to many to be able to banish a test which was made in Germany and bears a German name, in favour of one which was made at home and bears the unassuming title of the "Gel" test.

FROM the account of the proceedings of the British Oto-laryngological Society, which appears in another column, it will be seen that the President, Mr. Charles Heath, and the members generally, take a very different view of the proper course to adopt in reference to the Wittenberg Camp abominations from that which was decided upon at a recent meeting of the Laryngological Section of the Royal Society of Medicine. At a recent meeting of the Section Sir William Milligan proposed, and Mr. Richard Lake seconded, a resolution framed in much the same spirit as that which prompted the action of Mr. Charles Heath. The resolution of the Section was defeated by twelve votes to nine; that proposed by Mr. Charles Heath was carried, not only with unanimity, but with enthusiasm. It is quite obvious that if expression is to be given to the feelings of abhorrence with which all medical men regard the behaviour of the monster Aschenbach and those who were behind him, the present is the proper moment for those feelings to become articulate. It is useless to wait until the end of the war, when there will be many reckonings of several kinds to be adjusted. Mr. Charles Heath and his Society have set an excellent example which I hope other medical bodies will not be tardy in following.

SINAPIS.

ELECTRO-THERAPEUTICS AND THE WOUNDED.

ONE of the little-discussed, but not the least important, of the many side issues of the war has been the enormous influx of hitherto untrained women into the lighter branches of the nursing profession. Prompted by a laudable desire to be of use to the wounded combatants, these women have joined the schools for massage in unprecedented numbers during the past year and a half. Massage attracts by the comparative brevity of its course of study and the rapid promotion to independent occupation without the severe and often unpleasant duties which fall to the lot of nurse and probationer working the livelong day in hospital wards. More than massage, however, is required for the stiffened and paralysed limbs of the convalescent soldier. The rapid and beneficial results of carefully graduated electrical applications are well known to every competent student of electro-therapeutics. Very soon after the war began it became obvious that the demand was far greater than the supply, that the practitioners

skilled in electro-therapy and the nurses capable of carrying out their directions were too few to cope with the vast numbers of convalescents requiring their services. The Incorporated Society of Trained Masseuses endeavoured to meet this need by instituting courses of training in medical electricity, and certificates were given to those masseuses who passed an examination conducted by physicians. A text-book designed to meet the requirements of these students has been written by Dr. McGill (1), and between the covers of the little volume are found all the necessary details to ensure a thorough understanding of every kind of cell, battery and bath in common use with electrical treatment. The newly qualified doctor and the medical student should find these minute descriptions of the various simpler apparatus and the general indications for their employment a useful introduction to the deeper treatises at present consulted only by the skilled specialist. We should hesitate to place such a publication in the hands of every student of massage, because we find no mention of the evil results of erroneous methods of treatment, no warning of risks less obvious, but not less injurious, than the "earth currents" very properly described and dealt with by the author. The nurse who has spent long years in hospital wards may avoid the dangers which are lightly incurred by the ignorant and hastily trained masseuse; it is less probable that she would give a light bath to a patient whose pulse is liable to run "over 100 and become irregular," or continue faradic applications to facial paralysis "till contraction ensues."

The war masseuse may easily commit such errors. Nor will the patient escape scatheless though the text-book injunctions to cease treatment on the occurrence of such symptoms be strictly adhered to. The average doctor may be unable to assist the electrically-trained masseuse, but the study and science of electro-therapy is now so far advanced that the soldier ought to have the advice and supervision of the specialist in that subject. No patient is permitted to take Nauheim or other medicated baths at his own discretion, and it is of even greater importance that the maimed arms and legs of our heroes should be guided back to usefulness by the careful treatment obtainable only from the electro-therapist who has years of observation to guide his prescription of dose, frequency and modality of electrical application. We speak with concern and anxiety, for it has come to our knowledge that in some cases the decision as to the treatment of helpless limbs has been left to the manufacturing electricians who supply the battery to the masseuse. That such incompetence can have such power at the present day, when in America and in many European countries there flourish medical journals devoted entirely to the study of electro-therapy, is a disgrace that demands prompt remedy. The life-long consequences, for good and evil, of electrical treatment should be made more widely known, so that the soldier's advisers can demand and expect for him the expert services of the electro-therapist just as readily as they can at present obtain the skilled assistance of the dermatologist, the aurist and the oculist.

CURRENT TOPICS.

The Irish Medical Association.

THE presidential address to the Irish Medical Association, delivered last Wednesday by Dr. Marlay Blake, and published in this issue, deals with most of the activities of the Association in the past year, as well as with those that may fairly be expected of it in the future. No better example of the value of united action can be found than the history of the successful struggle of the Irish medical profession over the certification question. The Irish Medical Committee, supported loyally and generously by both the Irish Medical Association and the British Medical Association, and by the great body of the rank and file of the profession, succeeded in overcoming a seemingly invincible opposition—society "bosses," political powers, official hostility, and, worse than all, the traitorous attacks of a small—fortunately a very small—clique within the profession. From the victory of the Irish Medical Committee, the Irish medical profession can learn many lessons. There are, as Dr. Blake pointed out, many questions pending which will require all the strength and all the brains of the profession to meet. Poor Law Reform is long overdue—it is certain to be one of the first problems to be tackled by an Irish legislature, in whatever form that legislature may be embodied. The medical profession of Ireland must remember—when that question rises—that it is only by union it can maintain its interests intact and can make its demands effective.

Post-Graduate Work

IMMERSION in clinical practice, with practical cessation of opportunities for study, is the common fate of most medical men. It is urged that such a system is mistaken, inasmuch as it fails to keep one abreast of modern research, and of its applied results. Thus, under existing circumstances, a practitioner employs the standard of knowledge, and degree of *technique* existing at the time of his qualification, plus a modern smattering picked up at academic meetings, or gleaned from chance perusals of transactions. In the British Navy, impressed by the situation, it has been made compulsory for surgeons to present themselves for a series of examinations in their post-graduate career, with the object of preventing professional stagnation and rust. As an alternative, in civilian work, it is *optional* for a conscientious practitioner to study for certain further higher qualifications, but such a casual system hardly meets the case under consideration. It might be possible to introduce some compulsory element, necessitating attendance periodically at a well recognised medical centre, for purposes of a return to student methods. Compulsion has an ugly sound for many. Yet such an arrangement might conduce to an increase in general efficiency, and, moreover, would save the elderly from their great handicap, namely, unequal competition with their more recently qualified juniors.

Books as Germ-Carriers.

VERY numerous are the cases of contagious disease attributed to the reading of infected books, for books are to the lay mind such obvious germ-carriers. A child suffering from diphtheria breathes upon the pages of a book which presently is borrowed by another child—naturally the second child acquires diphtheria too. Dr. Laubach considers the investigation of this matter of some im-

portance, and in the current number of the *Bulletin of the Johns Hopkins Hospital* he has published the results of some interesting experiments dealing with the subject. In one set of experiments cultures were made from books obtained from a public library chiefly used by poor children. In no instance were definite pathogenic bacteria discovered either by cultivation or by inoculation into animals, although in two instances *B. coli* was found. Then search was made for *B. diphtheriæ* in books known to have been handled by children suffering from the disease. In every instance the search failed. The findings were also uniformly negative as regards the tubercle bacillus. Finally, sterile books were deliberately smeared with cultures of virulent organisms, and then kept under various conditions in order that the influence of these conditions upon the life of the organisms might be determined. Those most favourable for survival of the organisms were found to be moisture, absence of daylight and room temperature. Under these circumstances *B. coli* could live for five or six months, while *B. diphtheriæ* was found of undiminished virulence after one or two months. Direct sunlight and diffuse daylight are the most efficient germicides, the former causing the life of the organism to be measured in hours. In conclusion, Dr. Laubach states that although there is thus no empirical reason for maintaining that books serve as vehicles for infection, yet the fact that pathogenic bacteria can be recovered from artificially infected books after long periods of time is sufficient reason for insisting upon the thorough disinfection of books which have been handled by infective patients.

Post Mortem Cæsarean Section.

THE obstetrician is from time to time severely oppressed by the dual responsibility. Occasionally this may be relieved by the intra-uterine death of the fœtus, but in cases where death overtakes the undelivered woman all his resource and skill will be required to save the life of the child. Dr. Lee states that the fœtus may live from 5 to 20 minutes after the mother's death, and immediate action is therefore necessary. Considerable strength of mind is needed, for the operator must be absolutely convinced of the mother's death within one or two minutes of its occurrence, so as to abandon all attempts at resuscitation and to open the abdomen without waiting for aseptic precautions in order to extract the child without delay. In the current number of the *American Journal of Obstetrics* Dr. James A. Harrar, of New York, reports the cases of *post mortem* Cæsarean Section. Of these, two children only lived to be discharged from hospital, three were stillborn, four failed to breathe, one died soon after delivery, and one died on the sixth day of pneumonia (one delivery was of twins). Dr. Harrar states that the child has a better chance if the mother's death has been sudden, as in apoplexy hæmorrhage, etc., while it will live for a shorter time *in utero* where death has been more gradual, as in tuberculosis, or heart disease. In this series of cases the longest interval between the death of the mother and the delivery of a living infant was 7 minutes. One child delivered 20 minutes after the mother's death had a feebly beating heart, but made no attempt at respiration. Hallman in 1914 collected 68 cases from recent literature with 61 to 68 per cent. of living children, but it is probable that very many unsuccessful cases have never been recorded, and hence these statistics cannot be regarded as of absolute value. The legal aspect of the procedure is discussed at length in

the same journal by Mr. G. W. Whiteside, counsel to the Medical Society of the County of New York. He holds that the operation is justifiable even without the husband's consent, and that the surgeon might incur criminal responsibility by neglecting to operate. On the other hand, the procedure might be regarded as an autopsy, and therefore illegal without consent. The early laws of the Romans decreed Caesarean Section in pregnant women dying undelivered, but our present day system has omitted to make provision for such cases.

Conscientious Objectors and the Indian Civil Service.

THE Government have accepted a proposal of the Secretary of State for India to render conscientious objectors to military service ineligible for the Indian Civil Service.

The rule declares the inadmissibility of any person "who has made before any tribunal established under the Military Service Acts, 1916, application for certificates of exemption from the provisions of those Acts on the ground that he has conscientious objection to the undertaking of combatant service."

Under the Act of 1858 the Service has to be recruited exclusively by open competitive examination of British subjects; but an emergency Act passed last year provided that this requirement need not apply to more than one-fourth of persons admitted to the Service during the war and for a period of two years thereafter. The Secretary of State was given power to fill the remaining vacancies by nomination, and the rules will provide that in the case of European, as distinct from Indian, candidates, service with the armed forces of the Crown of a certain length and nature must be a condition of selection. As the rule takes immediate effect it will apply to the examination commencing on August 1st, for which six vacancies only were notified. The mere application for a certificate disqualifies, and in the event of refusal to grant it by a tribunal, subsequent war service, whether in a combatant or non-combatant capacity, will not remove the bar.

We cordially approve of Mr. Chamberlain's recommendation, though we confess to a feeling of pleasant surprise at its adoption by the Government, which has hitherto treated the conscientious objector with a tenderness almost morbid in its intensity. The step is an act of justice to the patriotic youth of our country. In peace time hundreds of public school and university students aspire to the Indian Civil Service, and enter it after strenuous study and stiff competitive examination. The war records of our schools and universities show what these youths have done. They have risked their careers and set aside their ambitions—in many cases have given their lives—to serve their King and country by defending the rights and liberties of the Empire.

The conscientious objector sits safe at home with a whole skin through the heroism of his betters. We have heard a lot recently about "job-snatching." We are glad the Secretary for India means to see that the pampering of the C.O. is to have no recognition in his department. The mind of the conscientious objector is not the type we wish for in the rulers of our great dependency.

Captain D. A. Ross Haddon, R.A.M.C., attached Royal Scots, has been wounded for the second time. A native of Hawick and educated at Fettes College, he graduated M.B., Ch.B. at Edinburgh in 1913. He first saw service with the 10th Royal Scots, and after recovering from wounds he was transferred to the R.A.M.C.

PERSONAL.

MR. J. M. PALMER, F.R.C.S.I., has been appointed a Deputy Lieutenant for the County of Armagh.

SIR ALFRED PEARCE GOULD has been elected Vice-Chancellor of the University of London for a second term of Office—namely, until June, 1917.

DR. JAMES BURNET, M.A., M.D., M.R.C.P.E., has been appointed Medical Adviser to the Local and General Munitions Tribunals for the Edinburgh district.

DR. R. A. FLEMING has been appointed on the staff of the King's Body Guard for Scotland (Royal Company of Archers), in place of the late Dr. W. Allan Jamieson.

By a decree of the Board and Visitors of Trinity College, Dublin, Sir Robert Henry Woods, M.D., M.C., has been appointed Honorary Professor of Laryngology and Otology.

CAPT. A. D. STIRLING, R.A.M.C., who has been mentioned in dispatches, graduated M.B., Ch.B., with distinction, at St. Andrews University in 1907. His name also appeared a year ago in Sir John French's dispatch.

SIR ALFRED KEOGH, Director-General of Army Medical Services, has been elected an honorary freeman of the Society of Apothecaries of London, "in recognition of his peculiar services to the State and the medical profession."

CAPT. ALEXANDER FINDLATER, R.A.M.C., Medical Officer at Hendon Union Infirmary, of North Lodge, Edgware, has been presented by residents of Edgware, Stanmore and district, with an illuminated address, an album, and a cheque for £150, "on account," in recognition of his winning the D.S.O.

DR. A. E. LARKING has been appointed a magistrate for the borough of Buckingham. Dr. Larking is an old Volunteer officer, having been Surgeon-Captain of the East Kent Regiment. He started the Buckingham Division of the St. John Ambulance Brigade, which has done valuable V.A.D. work since the war, and recently formed a new nursing division, which comprises 20 members. He has held a seat on the Town Council.

CAPT. A. S. GLYNN, R.A.M.C., who has been mentioned in dispatches for the second time, is a well-known Watsonian, and was formerly a member of the famous Watsonian Rugby team. He is a well-known Edinburgh doctor, and has been in Flanders since the early days of the war. Since November, 1914, he has been serving in the trenches with the Northumberland Fusiliers. Capt. Glynn is a graduate of Edinburgh University.

THE Sisters at the West Ham Hospital are to be paid £3 a year as a war bonus, and the nurses £2 a year.

DR. A. D. WOOLF, M.D., 13, The Avenue, Highams Park, has been appointed Divisional Surgeon in the St. John Ambulance Brigade.

THE Frank Smart Prizes at Cambridge have been awarded to Mr. C. P. Dutt, B.A., Queens' (Botany), and Mr. M. A. Husain, B.A., Christ's (Zoology).

MRS. SARAH HALSTED SANDFORD, of Sandford, Salop, left £1,000 each to the Whitchurch Infirmary, and the Alexandra Hospital, Rhyl; £10 each to the Salop Infirmary, and the Salop Eye and Ear Infirmary.

THE CHADWICK TRUST LECTURES.

LECTURE II.—FRIGORISM.

By PROF. SHERIDAN DELÉPINE, M.B., C.M., M.Sc.,

Director of the Public Health Laboratory, University of Manchester.

FROST-BITE AS IT OCCURS AT HIGH ALTITUDES AND IN ARCTIC REGIONS.

My experience of frost-bite has been gained among the snows and glaciers of Swiss mountains, and as far as I am personally concerned it has fortunately been limited to frost-bites of the first degree. I have also seen the terrible effects of more severe frost-bites in Bourbaki's army when it took refuge on Swiss soil during the severe 1870-71 winter. The accounts which I have read of the effects of exposure to cold in Arctic regions seem to indicate that the characters and mode of occurrence of frost-bite in these regions are very much the same as in our part of the world, but that owing to the intensity of the cold, their frequency and the rapidity of their onset are very much greater.

It is a matter of common experience among Alpinists that it is possible, when the weather is fine, to walk for hours over hard frozen ground, snow or ice, without experiencing any discomfort, even when the thermometer indicates temperatures 10° to 25° below 0° C., and the air is so cold that the moisture of the breath freezes hard as soon as it condenses on the moustache or on adjoining garments. At such times the skin of the face feels stiff and tingles as if exposed to a hot fire, the tips of the nose, ears, or fingers may ache more or less. From time to time one discovers on touching one's ears or nose that these parts are deprived of sensation. When this is noticed in time the circulation is generally rapidly restored if one rubs the frost-bitten organs with soft, dry snow. The parts so affected are generally pale and somewhat bluish, they may look shrunken, they certainly are not swollen or deeply coloured. When the process extends to the whole body, as when a fatal sleep supervenes under the influence of cold and fatigue, the various parts of the body retain their normal appearance, except as regards colour. As circulation returns, under the influence of friction or movement, a frost-bitten region becomes red and has a tendency to swell; at the same time it becomes the seat of painful burning and tingling sensations. This type of frost-bite is said by surgical writers to be of the first degree.

When a part has remained frozen so long that circulation cannot be re-established, death of the affected tissues takes place, and the adjoining regions become inflamed. The dead parts in such cases generally dry up (dry gangrene). If imperfect circulation is re-established through the damaged tissue, the frost-bitten organ may become the seat of serious inflammatory changes, and may die slowly, passing into a state of moist gangrene.

Death of the tissues may therefore result from the action of cold, in which case there is no inflammatory lesion, or it may be partly due to the action of cold and, to a greater or less extent, to the disturbances of circulation and the inflammation following partial recovery from frost-bite.

Exposure of unprotected parts of the body to the intense cold which at times prevails in Arctic regions is followed almost instantly by frost-bite, more especially when there is much wind and after sunset.

The following passages taken from the account of Antarctic adventure, published two years ago by Mr. Raymond E. Priestley, are sufficient to indicate the conditions favouring the occurrence of frost-bite in Antarctic regions:—

"The gale commenced actually while Campbell was taking the observations, and his fingers were so benumbed that he was unlucky enough to break the maximum thermometer. He had not been prepared for wind, and had gone out without his wind-proof helmet or any fur mitts, and so his nose and fingers were badly frost-bitten, and he did not know exactly what he was doing with the instruments." (p. 104.)

"The temperature during this journey had been decidedly lower than during the last, and on the morning of the 13th we registered our lowest temperature for the year, -42.8° F., and there was on this day a fair crop of frost-bitten faces, fingers, and feet." (p. 158.)

"The temperature had so far remained obstinately below zero, ranging between -20° F. and -28° F., but the weather was beautifully clear and the cold, combined with bright sun, was really no hardship. It was not until the evening, when the sun dipped behind the Admiralty Range, that frost-bites became at all common." (p. 167.)

"May was ushered in quite appropriately with a blighting westerly wind. The sea ice which had formed again on the bay during the last day or two of April was driven out to the horizon, and several members of the party who were working outside sustained severe frost-bites. Browning in particular returned to the cave with his whole hand and wrist quite dead and white, and he was some time restoring its circulation." (p. 265.)

"July 21st was marked by what was perhaps the coldest wind yet. I don't know how many degrees of frost there were, but I felt as if I had no underclothes on at all, and in three minutes I had three body frost-bites, and hurried back as fast as I could against the wind in time to stop the others going down." (p. 319.)

"I put in a couple of hours mending one pair of my wind-proof trousers, and Browning put in the same time on my working pair, which were rotten with blubber." (p. 320.)

When the cold is not excessive and the air is dry, ordinary walking boots with thick woollen stockings are quite sufficient protection for the feet if the rest of the body is warmly clad. In ordinary winter clothes I have often walked for eight or ten hours in dry snow at high altitudes in the Swiss mountains when the temperature of the air ranged between -10° and -20° C. without any other inconvenience than that caused by the necessity of rubbing occasionally my nose and ears with snow when loss of sensation indicated the possibility of frost-bite.

Once when the temperature was at least 10° below 0° C., I fell through a hole in the ice and was momentarily immersed nearly up to the waist in water. After taking some violent exercise, during which the outer parts of my garments froze hard,

the sensation of wetness and coldness disappeared rapidly, and I was able to walk several miles without other discomfort than that caused by the stiffness of part of my outer garments. The weather was very fine, and the air, though cold, was dry and still.

Coming from higher regions where air and snow are dry, to lowlands where thaw has set in, it may become necessary to wade through half-melted snow or pools of snow-water; when this happens a sensation of extreme cold is rapidly experienced, even when the temperature of the air is several degrees above the freezing point. Under these circumstances the feet are liable to get wet, and when this occurs they often suffer more than other parts of the body.

Insufficiency or unsuitability of food and clothing, constriction of extremities, inactivity, illness, excessive fatigue, previous occurrence of frost-bite, are all very important well-known predisposing factors which I need not discuss at this stage.

"TRENCH-FOOT"—SOME EXPERIENCES OF THE ARMY IN FRANCE DURING THE WINTER 1914-15.

During the winter 1914-15, a large number of soldiers in the north of France suffered from exposure to wet cold in the trenches, and this resulted in lesions which have variously been termed frost-bite, water-bite, chilled-foot, boot-bite. Notwithstanding the improvement which has taken place since then, a number of men were invalidated last winter owing to the same cause. Mr. Tennant (*a*), in the House of Commons on December 8th, 1915, stated that during the week ending November 27th there were approximately 770 cases of trench-foot reported from France. Captain Page (*b*), after examining 332 cases, classified as frost-bite, *soon after they had been disabled*, found that a large percentage of cases resulted from exposure to wet when the temperature was above freezing point. He estimated that only 10 per cent. of the men had suffered from the effects of actual frost. There was a regular history of exposure in wet trenches from 24 to 72 hours. Cases which had been exposed to frost after wet had, as a rule, been the most severe. He describes three types of frost-bite, the first two of which correspond to the first degree of older writers.

Several other observers have published valuable contributions upon the subject of trench-foot. For the present purpose I will only refer to the information supplied in two or three contributions regarding the circumstances under which trench-foot occurred.

Major Miller had the opportunity of examining (after their return to England) 376 soldiers invalided on account of trench-foot. The history which he obtained from 100 of these examined consecutively established the fact that every one of these men had been standing in mud and water to a depth of between 18 inches and three feet for many hours, and that they had been wearing short boots with more than one pair of socks, and the majority also wore putties. Sixty-five of these men said they had been exposed to freezing temperature.

Lorrain-Smith, James Ritchie and James Dawson, who examined 51 cases of frost-bite after their return to England, found that all these patients, except one, had been fighting in trenches. Except in two cases, the trenches had been wet, and very frequently on their way to them the men had been obliged to wade through mud, sometimes up to the waist. The muddy water was not usually frozen, although sometimes in the morning there would be crystals of ice on it. In only one case was there frost-bite of the hands.

The total number of cases referred to in these communications amounts to over 750, and from the statements made by the writers one may infer that more than 70 per cent. of the men suffering from trench-foot had not been exposed to freezing temperatures.

Most observers agree that, generally speaking, the men affected with trench-foot were well clad and fed, but that a certain proportion of them had suffered from nervous strain and forced inactivity.

The conditions of trench warfare had made it necessary for the men to remain for many hours consecutively almost motionless and in cramped positions, while their feet or legs were frequently immersed in water or watery mud at a temperature generally above the freezing point. This was not the result of carelessness or ignorance, for these men must have experienced intense, and at times almost intolerable, discomfort, and they had also been warned of their danger by one of the Army Routine Orders, dated November 23rd, 1914 (issued therefore at the beginning of the first winter).

The facts which have been referred to show that cold may cause serious lesions even when the temperature is still distinctly above freezing point.

This was obviously the case with regard to most of the soldiers who suffered from what has been called "frost-bite." It is, however, very doubtful whether the lesions from which these men were suffering had in their initial stage the same characters as those which are produced under the influence of great cold, and to which the name of frost-bite has very properly been given. That exposure to wet cold may lead ultimately to inflammation and gangrene does not prove that there are no differences in the mode of production of the original lesions.

EFFECTS OF EXPOSURE TO COLD—FRIGORISM.

Exposure to cold may have a stimulating effect beneficial to the activity of the tissues, and result in an increased production of heat, but when the amount of heat produced in the body is insufficient to compensate for the loss taking place on its surface, cooling occurs more or less rapidly. The parts most affected are those which are most exposed and in which the circulation of the blood is less active. It may also happen that owing to pressure, inactivity of muscles, or other reasons, the flow of blood through a part is so reduced that the amount of heat conveyed to the part is insufficient to compensate for the losses; this may occur even though heat production in the rest of the body is quite normal.

When general or local cooling reaches a certain degree, the functions of the tissues are interfered with, and the amount of damage done is determined by the degree and the duration of the cooling. Cold alone may, if sufficiently prolonged, cause death. It must, however, be always remembered that many of the lesions which are attributable to cold are due to the reaction which takes place after cold has ceased to act, and when blood circulates again more or less freely through damaged tissues.

It is convenient to group under the term "frigorism" the various morbid states which are attributable to the action of cold on living tissues.

Frigorism may be general or local. *This state is produced when cooling of the body or part of it is progressive.* It may be produced slowly by exposure to temperatures above the freezing point but many degrees below the normal temperature of the body, as frequently occurs in wet trenches. It may be produced rapidly by exposure to severe cold, as is the case in Arctic regions.

In the former case the parts are never frozen, and the damage to the tissues is produced gradually. In the latter case the frost-bitten parts are liable to

(a) *Lancet* (December), 1915, II., p. 1379.

(b) *Lancet* (March), 1915, I., p. 590.

actual freezing, and death of the tissues may occur rapidly.

Many cases of "trench-foot" are good instances of *frigorism without frost-bite*; on the other hand, the form of *frigorism* usually observed in the Arctic regions is *frigorism with frost-bite*. These distinctions are not without their importance. They indicate both the resemblances and the differences between the effects of exposure to various degrees of cold.

There remains now to explain why soldiers exposed in trenches to a moderate amount of cold suffered more than Arctic explorers exposed to very much more intense cold, and why trench *frigorism* affected almost invariably the feet and legs and very seldom the hands and face, while the reverse is true of frost-bites due to much more severe cold.

The difference may be explained on general grounds if one takes account of all the circumstances.

When a body is surrounded by a medium at a lower temperature than itself, heat passes from that body into the medium until the temperature of both is the same. The rapidity of this exchange is determined by many well-known factors. The loss of heat from any part of the body of an animal is governed mostly by the following conditions:—

- (1) The temperature, the thermo-conductivity, the volume and the movements of the external medium.
- (2) The duration of the exposure.
- (3) The bulk, movements, and superficial area of the part exposed.
- (4) The thermo-conductivity of the tissues, and more particularly of the integuments.
- (5) The amount and velocity of the flow of blood through the part.
- (6) The state of nutrition, activity and soundness of the tissues locally and generally (the kind and amount of food available being included under nutrition).

In a recent letter (a), Sir William Osler has insisted upon the importance of the venous stasis resulting from inertia of the leg muscles. Free circulation of the blood in parts exposed to cold is the natural and automatic method of compensation against the loss of heat due to exposure to cold, and muscular activity, provided it is not excessive, promotes good circulation. I must, however, point out that, even when the circulation is normal, if the amount of heat absorbed by surrounding media is in excess of the maximum amount of heat which can be supplied by the blood, then cooling of the part invariably takes place. Thus, a strong swimmer often succumbs to the effects of immersion in cold water long before his muscular power is exhausted. Persons shipwrecked in cold water are more rapidly affected by cold than by their exertions.

Stripping of the body, as commonly practised in such cases, facilitates swimming, but also favours rapid cooling, and is probably more detrimental than useful when the water is cold.

In some Alpine lakes there are zones or areas where, even on the hottest days of summer, the water remains very cold. This is due to springs or currents of water coming more or less directly from the glaciers. When a swimmer passes from the surrounding warmer water (where the body loses no more heat than is quite comfortable) into these cold areas he is rapidly numbed and liable to fatal cramps.

EXPERIMENTAL STUDY OF FRIGORISM.

The share taken by the external media in the rate of cooling of the body or of its parts can be demonstrated and estimated by means of compara-

tively simple experiments. Several of these have been described in previous communications, in which details of the methods used have also been given. These experiments may be summed up as follows:—

The subject used in most of these experiments was a healthy person no longer young, but well fed and with good circulation. The heat production was not above normal. In some sets of experiments tests were applied simultaneously either to the two feet or to the two hands; in other sets the tests were applied in rapid succession to the same parts of the body, so that there was no appreciable difference in the production of body heat. Control experiments carried out singly at intervals gave the same results as the simultaneous or consecutive ones.

(a) When the bare hand and arm were exposed to dry, still air at $+10^{\circ}\text{C}$., a not unpleasant sensation of coolness was experienced, but if they were plunged in water at $+10^{\circ}\text{C}$. the skin was rapidly chilled, and after a few minutes felt very cold and uncomfortable.

(b) When the hands and feet were exposed to dry, still, cold air at 1° or 2° below freezing point, for ten minutes they felt cool but not uncomfortable, and the temperature of the skin fell slightly, but afterwards remained constant and not much below normal. When the hands and feet were afterwards plunged in water at the same temperature, a sensation of intense cold was immediately experienced, and the temperature of the skin fell rapidly much below the normal and continued to fall until it approached that of the water. In less than half a minute the sense of touch was almost entirely lost, the part was numb and the seat of unpleasant tingling sensations. Within one minute the hand and foot became painful. Before the end of another minute movements of the fingers and toes were frequently accompanied by cramps. When this occurred, the indicated temperature of the skin, which originally was about 30°C ., had generally fallen to 10°C ., or even less. At the end of three minutes movements had generally become distinctly difficult and painful, and the temperature had fallen to about 7°C . After a further interval of three or four minutes the temperature had fallen to 1° or 2°C ., the part exposed felt like a weight hanging to the arm or leg, sensation being lost, and voluntary movements of the toes and fingers quite impossible. Thus, in about seven minutes the parts immersed in water at a temperature near the freezing point had passed into a state undistinguishable from what has been described as frost-bite of the first degree.

From this state, after being well dried and rubbed, the hand and foot recovered rapidly, and became the seat of the painful sensations and congestion such as are also observed in parts recovering from ordinary frost-bite. It will be noticed that in these experiments there was a progressive loss of heat, and that the temperature of the skin fell gradually till it approached very nearly that of the external medium. This was apparently due to the fact that more heat passed from the immersed hand or foot into the surrounding water than could be brought to the parts by the circulating blood. This was made clear by the following experiment:—

(c) Instead of being plunged into a large amount of cold water, the hand was plunged into double its volume of water at freezing temperature. The first effects were exactly the same as those previously recorded, but the cooling of the hand was slower, and reached its maximum in about twelve minutes. The symptoms of *frigorism* also reached their maximum at the same time. After this the temperature of the hand rose again until at the end of

half an hour it was 12.5° C., and by that time nearly all symptoms of frigorism had disappeared.

While the temperature of the hand was falling that of the water was rising, and twenty minutes after the beginning of the experiment it had risen to nearly the same point as that to which the hand had fallen, after which there was a parallel rise of temperature, both in the hand and in the water. Almost immediately after the progressive cooling of the hand had ceased, the symptoms of frigorism began to abate.

(d) When, before being plunged into cold water, the hand and foot were covered with a thick woollen glove or sock, cooling took place much more slowly than when these parts were entirely unprotected; this was specially the case when the immersed parts and the water were still. This was undoubtedly due to the fact that the water imprisoned in the meshes of the woollen fabric, after it had been warmed by the hand, could not diffuse so readily into the surrounding cold water as when the skin was bare. This to a certain extent limited the amount of cold water having access to the skin, and brought about conditions not unlike those of experiment (c). This experiment is in accord with what has already been said regarding the disadvantages of stripping after shipwreck.

These experiments, selected from amongst a much greater number, show that the differences in the effects of exposure to cold dry air or to cold water are due to the fact that water conducts heat much better than air. While the amount of heat lost by a part exposed to still air at freezing temperature can be rapidly compensated for by the amount brought to the part by the circulating blood, the reverse is the case when the part is immersed in cold water. The effect of this difference is that the cooling due to cold, still water at 0° C. is progressive, while that due to cold, still air at 0° C. is not.

PREVENTION OF FROST-BITE.

The facts which I have brought forward indicate clearly how the forms of frigorism which have been popularly termed "trench-foot" can be guarded against, but before discussing the special method which I have recommended for preventive purposes. I wish to make it clear that it is intended only to meet those special circumstances prevailing in the trenches under which the usual methods become insufficient.

Some writers have assumed that choice was generally possible, for they have suggested that trench-foot might be prevented by shortening the duration of the periods spent in the trenches, by taking more frequent muscular exercise, by keeping the trenches dry, etc., etc.

All these are no doubt counsels of perfection which must always be before the mind of responsible officers; as a matter of fact, the Army Order issued at the beginning of the first winter clearly shows that the superior command had not neglected to instruct the Army regarding the importance of these points.

I think, therefore, that it is safe to assume that men who endured what they had to endure in wet trenches during the last two winters did not do so as a matter of choice, but under the stress of necessity. We have, therefore, to face the following question:—

What is the best way to prevent the occurrence of frigorism when men are in the necessity of spending many consecutive hours in a state of muscular inactivity, and with their feet plunged in cold water or mud?

When the feet and legs, protected by waterproof waders, are plunged into cold water, a layer of air is imprisoned between the skin and the inner surface

of the wader, and it is this layer of air which prevents rapid loss of heat. The thickness and the composition of the waterproof covering are comparatively of little importance. This can be proved by the following simple experiment:—

The dry foot and leg are covered, first, with a dry, thick, loosely-knitted, woollen stocking, and outside this by a waterproof covering made of thin oil-silk, and then immersed in ice-cold water, or in a refrigerating mixture at a temperature a few degrees below freezing point.

Instead of the parts so immersed being painfully affected in a few minutes by cold, as has been shown to occur when the skin is unprotected, they remain for several hours warm enough to discharge their functions, and no evidence of frigorism is observed. The indicated temperature of the skin, instead of falling rapidly towards that of the water, is only slightly reduced, and remains stationary. When the air imprisoned in the wader becomes moist, a slow fall of temperature is observed.

That the protection afforded by the waterproof wader is not due to the nature of the material of which it is made can be proved by pouring some warm water between the skin and the wader. When the air in the space between the wader and the skin is replaced by water, marked and progressive cooling of the skin takes place very rapidly, though not so rapidly as when the water next to the skin is not rendered stationary.

Many experiments of this kind convinced me that when immersion of the legs and feet in cold water or mud becomes a matter of necessity, the best protection against frigorism ("trench-foot" so-called) is provided by good waterproof waders.

My experiments have, in addition, led me to recommend oil-silk waders as having distinct advantages over heavier waders. In order to obtain good oil-silk bags it is necessary to avoid sewn seams, and to have resort to apposition seams. These are made readily enough by careful workmen, but up to lately manufacturers who have attempted the production of these bags have succeeded only in making 70 good bags out of every 100. With proper care one should be able to obtain constantly good results.

Manufacturers of india-rubber goods have been more successful, and so far the method which I have recommended has been carried out chiefly by means of india-rubber waders. Many imperfect waders have, however, been used, and failures due to this must not be accepted as evidence against the method.

The bags I used for the purpose of the practical tests, conducted during the early months of last year, extended up to the knee, and could be worn for twelve or fifteen hours at a time without discomfort, and without undue condensation of perspiration. When in later experiments, bags reaching up to the hip were used, it was found, especially after a march, that abundant condensation of perspiration took place on the inner surface of the bag. This led to an accumulation of water round the foot and reduced to a considerable extent the protection afforded by the bags.

It is obvious that if the use of long bags is essential, these bags should not be worn during long marches, or, if they must be worn, their length should be reduced by suitable folding during the march.

I do not think, however, that waders of any kind are suitable for wear during long marches. What is important is that the men wearing them in the trenches should be able to leave the trenches and march or run without the waders interfering with the freedom of their movements. One of the

essentials of success is that the foot and leg should be left entirely free from any pressure causing a sensation of constriction, or tightness, or interfering with the freedom of circulation. The foot should be dry and warm when the wader is put on.

Large boots and socks are indispensable; the inner woollen sock should be thick, the outer sock should be large enough to draw easily over the oil-silk bag. It should not be made of material liable to shrink when wet. In my first tests both the inner and the outer socks were woollen. (See *British Medical Journal*, II., December 18th, 1915, for mode of wear and care of waders.)

ORIGINAL PAPERS.

A NEW AND SIMPLE TEST FOR SYPHILIS.

By J. E. R. McDONAGH, F.R.C.S.,
Surgeon, London Lock Hospital.

DURING the years 1913-14 I undertook a series of experiments with the view of discovering the rationale of the Wassermann reaction (1), since I thought it rather unscientific to interpret the results, as we did, of a reaction about which we know nothing. The result of the work was to show that the Wassermann reaction was a purely physical reaction, depending upon the size and number of the protein particles in syphilitic sera. From an ultra-microscopic examination of a number of sera it was evident that syphilitic sera contained not only more protein particles than normal sera, but also they were much bigger. Seeing that the colloidal particles were bigger and more numerous in the case of syphilis, I then conducted another series of experiments and found that syphilitic sera contained more protein nitrogen, more adsorbed amino-groups, and more adsorbed electrolytes than normal sera. The last point was also proved indirectly by comparing the clotting time of the various sera (2). It became clear, then, that the colloidal particles were protein or, more strictly speaking, lipid-protein, as proved by my micro-chemical work (3) upon plasma cells and the phases of the Leucocytozoon syphilitidis. These lipid-protein particles, as they exist in the serum in which they form the protective substance (or antibody, as it is often called), are perfect emulsoids—*i.e.*, their molecules contain water and they are partly in "solution." Being in solution, the particles are invisible to the naked eye, but if they are robbed of the salts attached to them they become visible as a precipitate, in which form they are known as suspensoids.

Now, it occurred to me that it ought to be possible to devise a simple test which would render such particles visible, the degree of precipitate formed and the rapidity with which it formed varying according to the number of particles in "solution" in a given serum.

For this purpose I used glacial acetic acid and then an electrolyte. I was originally under the impression that the change which occurred was a colloidal transformation of emulsoid to suspensoid (4). When I found later that the transformation was reversible and that the precipitate was soluble in water I came to the conclusion that the change which occurred was more probably a transformation of emulsoid to gelation. The "emulsoid-gelatine" or "Gel" test is therefore a better name than my original one of emulsoid-suspensoid, or E.-S. test, and that is how I shall in future refer to it.

From 5-20 cc. of blood are taken from the vein and the blood is allowed to clot in order to allow

the serum to separate out. It is better not to use a centrifuge. Also, the serum should not be incubated. An opaque serum or one tinged with hæmoglobin may be used. The serum should not be more than a few days old. In order to carry out the test satisfactorily it is necessary to have both a negative and a positive control—*i.e.*, a known non-syphilitic and a known syphilitic serum, because the time of year and the temperature of the room have an influence upon the reading of the results.

Two cc. of glacial acetic acid are now placed in a dry and clean test tube, to which is added 0.5 cc. of the serum to be tested. The tube is then shaken.

For every serum to be tested four dry and clean test tubes are taken—*i.e.*, if there are six sera including the two controls, a rack holding 24 tubes will be required.

One cc. of glacial acetic acid is first added to each tube, then into A tube 2 drops of the acid serum are placed, into B, 4 drops; into C, 6 drops; and into D 8 drops. The drops should be as small as possible, therefore a pipette is made out of narrow-bore glass tubing, tapering finely at the end. Needless to say the same pipette must be used for each series of tests, since the results obtained vary with the size of drop used. After the serum has been added and the tubes shaken, 0.2 cc. of a saturated solution of lanthanum sulphate in glacial acetic acid is added to each, and the tubes are again shaken. The tubes are then left undisturbed and the changes noted. In the positive control a precipitate soon forms in D, then in C, A and B, or C, B and A. Half an hour or so later the precipitate has fallen in all four tubes, leaving a clear solution above in tubes A and D. Later still the solution becomes clear in the other two tubes.

In the negative control the precipitate forms slowly, but in time it appears in all the tubes, but the solution above does not become absolutely clear in all four tubes even if left over till the next day; therefore it is the easiest thing possible, not only to differentiate a syphilitic from a non-syphilitic serum, but also to tell the grades of positivity and thereby gauge accurately the effect of treatment. I have tried this test on over 250 sera, controlling the first 200 by the Wassermann reaction, with the result that I am more than satisfied with it and consider the latter superfluous. In the 200 sera one gave a strong positive and two a slight positive Wassermann reaction, although the patient had never had syphilis so far as I could tell. By my test these three sera were negative. Out of these 200 cases 37 gave a negative Wassermann reaction, when the test should have been positive. By my test all these sera were positive.

The increase in the number and size of the lipid-globulin particles—*i.e.*, in cases of primary syphilis, can be detected by this new method more rapidly than by the Wassermann reaction. In the generalisation stage of syphilis a serum in which the particles are very fully laden with electrolytes may give a negative Wassermann reaction, while in the recurrent and late stages a negative Wassermann reaction is frequently obtained owing to the influence fatty acids have upon surface tension, and finally normal sera in which the protein particles have been rendered partly suspensoid, will always give a positive Wassermann reaction. These are disadvantages which can never be foreseen by the observer, and none of them influence the "Gel" test sufficiently to lead to a false reading being made.

To obtain uniform results it is advisable to test all sera drawn off on a certain day at the same time. The acid serum should also be freshly prepared, though those prepared a day or two before-

hand can be used, provided fresher sera are not included in the same series.

Instead of lanthanum sulphate, either a saturated solution of thorium sulphate or nitrate in glacial acetic acid may be used. The precipitate is formed most rapidly with thorium sulphate, then with thorium nitrate, and finally with lanthanum sulphate. According to the Hofmeister series the precipitating power of the sulphate anion in an acid medium is greater than that of the nitrate anion, but the precipitating power of thorium nitrate is greater than that of lanthanum sulphate, for the probable reason that the atomic weight of thorium is greater than that of lanthanum.

If the precipitate forms too quickly or the observer is called away before he has read his tests, all that is necessary is to add one cc. of water to each tube and to shake them on his return. The precipitate then partly goes back into "solution," but more completely in the case of a negative serum than in the case of a positive serum; therefore a syphilitic serum can be differentiated from a normal serum by the greater degree of gradient opacity in the four tubes of the former. The difference is particularly clear when thorium nitrate is used.

If 0.2 cc. of the electrolyte originally used be now added, down comes the precipitate again, in the positive tubes (syphilitic), quickly; in the negative tubes (non-syphilitic), slowly. The difference between a syphilitic and normal serum can in this way be best judged when thorium sulphate is used. With thorium nitrate, and still more so with lanthanum sulphate, the secondary precipitation occurs very slowly. This re-precipitation can even be repeated more than once, especially with thorium sulphate, but on the third occasion it takes some hours to form.

For some years now I have maintained that a positive Wassermann reaction is neither necessarily indicative of active syphilis nor a certain indication for further treatment (5). My view is that a positive reaction means that presumably the patient has had syphilis, and no more. As to whether my test is going to tell us more than this I cannot say, but my feeling is that it will not. I much doubt whether a bio-chemical test will ever be devised which will remove a clinical opinion from the premier position which it has hitherto held in medicine. The more I learn in medicine the more confident am I of the fact that the best diagnosis is the clinical one.

INTRAVENOUS SEROBACTERIN THERAPEUTICS :

A PRELIMINARY REPORT.*

By WILLIAM EGBERT ROBERTSON, M.D.,
Philadelphia.

BACTERIN treatment is an outgrowth of studies in immunity and should therefore be approached from that angle. It is not necessary, however, to review *in extenso* the subject of immunity, in a general way, well understood by all practising physicians who make any pretence at an effort to keep abreast of the times in medicine. It will suffice to outline in a sketchy way the chief features.

Immunity from certain infectious diseases in those who have already suffered an attack has been

known for nearly 3,000 years. For instance, Thucydides, who was born about 471 B.C., noted immunity in relation to the plague at Athens. Practical use of this fact seems to have been made use of first by the Chinese, who are said to have inoculated against smallpox by placing in the noses of healthy individuals crusts taken from those with active smallpox. In Europe it seems to have been recommended first by Lady Mary Wortley Montagu, wife of the British Ambassador to the Court of Turkey, who submitted her daughters to inoculation. She it was who said that the natives of the Orient submitted as readily to inoculation as the British did to the Bath waters. Of course, the dangers of this plan were the occasional severe and even fatal form of the malady in those inoculated and the ever-present danger of such individuals as foci of infection to others. Thus it soon fell into disrepute in more enlightened countries, and in the eighteenth century was contravened by law in the early American colonies. Jenner's work, and nearly a century later that of Pasteur, are the essential bases upon which our present superstructure has been reared; notably on the work of Pasteur, who appreciated the importance both of attenuation and passage through more or less resistant animals, as factors in the production of immunity, and their application in a therapeutic sense. The shortening of the incubation period in experimental rabies enabled him successfully to combat the disease in man. This he first accomplished in 1885. Haffkine, in 1892, using attenuated cholera vibrios and injecting them parenterally, gave us a means of lessening the morbidity and mortality of cholera. Salmon and Smith, in 1886, were first to show that for the production of immunity, living micro-organisms were not necessary, but that equally good results followed when bacteria killed by heat were injected, or even the products of bacteria from which the organisms had been removed by filtration. Prophylaxis against infections by means of cultures killed by heat or antiseptics we owe to Kolle, who, in 1896, suggested the plan as preferable to Haffkine's attenuated culture. It was in 1896 also that Sir Almroth Wright introduced the method of employing killed typhoid organisms for the purpose of immunisation against typhoid fever, and, in 1898, Shiga used the same method with dysentery bacilli against bacillary dysentery.

Thus far all the measures cited were prophylactic; methods for active immunisation. The first attempt at specific therapy was that of Koch, in 1890, with his tuberculin. This was a failure, however, at least as originally employed, and, in 1897, he introduced, rather as an immunising agent, a suspension of finely ground bacilli. To Wright we owe the present use of bacterins. He originally suggested the employment of killed micro-organisms as a therapeutic measure, especially in chronic affections. This was in 1904. He further suggested the advisability of employing autogenous strains. With the exception of organisms producing soluble toxins, however, notably diphtheria and tetanus, all the others, in which the toxin is endogenous—an integral part of the cell—their employment therapeutically has been more or less a disappointment. Even when used for active immunisation, with the exception of typhoid, the results have been indifferent, as was the case with the work of Wright with the pneumococcus, in his attempts to protect against pneumonia among the natives in India. As a therapeutic measure, however, in certain conditions, a fair measure of unanimity has come to exist among the profession. This is by no means general, for it is quite possible to recognise two camps—viz., those who are willing to admit the possible value of bacterins in local and

* *New York Medical Journal*, April 22nd, 1916.

chronic infections, but cannot see the rationale of employing them in acute infections, which for the most part are septicæmias, and in which the host is already labouring against an accumulation of toxin. Let us consider this latter phase first.

What happens when an individual falls ill with an acute illness of germ origin? The micro-organism, acting as an antigen, provokes the formation of reactive substances called antibodies, and whenever recovery occurs, it is because these bodies exist in sufficient amount to absorb or neutralise the toxins. In some instances the infection is so overwhelming that reaction is paralysed, so to speak. The organisms multiply too rapidly, and pour out too large an amount of toxin to be successfully dealt with. The basic fact, however, is that the same organism which begets the infection brings about the cure when recovery occurs. As has been seen, all the early work in immunity, dating from the time of Jenner, had for its object the attenuation of the infective material and shortening of the period of incubation. We seem to have lost sight of these facts in large measure in our therapeutic applications. To be sure, when we kill the organisms, we more than attenuate them, but we cannot carry the analogy further by attempting to shorten an incubation period in one already actively infected. What we aim to do is to cause an outpouring of antibodies which will overwhelm the toxin. But are we likely to do this when we inject bacterins subcutaneously? Apparently not, judging from the usual results in acute infectious diseases. Studies in anaphylaxis have shown the vastly greater susceptibility of an animal to intravenous injections than to those given subcutaneously or intramuscularly. This is true of all foreign proteins, and as bacteria are proteins and foreign, this is equally true of them. It seems possible that the variability of clinical results may be due to the fact that when we inject subcutaneously, or especially intramuscularly, prompt reactions and beneficent results follow only in cases in which by chance we happen to enter a vein.

Naturally, the ideal bacterin seems to be one robbed of its toxicogenic properties, but still retaining its antigenic properties. This has never been attained. In fact, as stated earlier, the same toxin which causes the infection, serves to awake in those who recover reactive substances which bring about the recovery. The sole question raised by dissenters is, Are we justified in acute infectious diseases in introducing in any manner into a host more of the same toxin from which he is already suffering the effects manifested by that particular disease entity? It must be borne in mind that immunity is probably brought about by absorption of the antibodies by the antigen, and when this is well balanced, the body cells are left free to produce antibodies in excess. The incubation period of a disease is one in which the foreign protein in the shape of the infecting organism is adapting itself to its environment, gradually awakening in the tissue cells that property of reaction, with the production of antibodies. This requires a variable period of time according to each particular disease. In acquired infectious diseases the living active agent multiplies more or less rapidly, and in proportion to the rapidity of increase, must require material for sustenance, and production and absorption of antibodies may suffer in consequence. In our therapeutic efforts in the use of bacterins, therefore, we should have in mind the elimination of the incubative stage of germs, obligatory in acquired disease, and by employing killed organisms we avoid the necessities and dangers of living micro-organisms, leaving them the function of absorption of antibodies, and the tissue cells free to produce more.

To effect the first part of this last proposition—viz., to elide the incubation stage, thereby introducing organisms already in a state capable of reacting favourably and at once upon the defensive mechanism, we employ the so-called serobacterins. These are prepared by sensitising micro-organisms with serum from an animal which has been immunised against that particular germ. It must be apparent, therefore, that the generally accepted plan of injecting dead, non-sensitised germs beneath the skin or into the muscle, and even this latter is rarely done, must fall far short of the results attainable by employing serobacterins intravenously. Several years before I became familiar with Besredka's work on sensitised bacterins, the possible advantages of such a plan occurred to me, and I had my interns in the Episcopal Hospital prepare them for me. In other instances I employed an immune serum taken from a patient who had recovered, and injected it with an ordinary or non-sensitised bacterin. Despite the employment of large doses, the results were indifferent until I gave them intravenously. Two diseases were studied with special care from the laboratory standpoint—viz., typhoid fever and pneumonia. In these, as a rule, the blood picture is fairly definite. In typhoid there is a leucopenia with a diminution of polynuclear neutrophils and a relative increase in lymphocytes, while in pneumonia there is a leucocytosis with an absolute increase in polynuclear neutrophils. It seemed to me that these should become more pronounced after the use of bacterins. This is not the case, however, when ordinary, non-sensitised bacterins are given. When serobacterins are injected subcutaneously, however, in most instances the expected happens, but when they are given intravenously, the results are very striking and leave no room for doubt. Whether this is constant I am as yet unable to say, as my opportunities for observation have not been sufficiently numerous.

When I was in the habit of giving bacterins subcutaneously I never felt satisfied that any definite result followed, whatever the dose and whether sensitised or non-sensitised bacterins were employed. When I gave them deeply into the muscle, however, I would occasionally get a sharp reaction, but the inconsistency of this result seemed to indicate something peculiar to the individual. In the light of my intravenous work, however, I now believe that reactions were obtained only when by chance I penetrated a vessel. As an instance of the possibilities resulting from the deliberate introduction of sensitised bacterins into the circulation, I may cite a case of typhoid fever in a lad of fifteen years at about the end of the second week of a typical attack. Five hundred millions each of sensitised typhoid and paratyphoid organisms were introduced intravenously. In seven minutes he had a chill which lasted twenty-three minutes, after which his temperature rapidly rose to 106° F. Twenty-four hours later it registered between 99° and 100°, and on the following day was down to 97° to hover between 97° and 98° for approximately a week, when a relapse developed. After allowing the relapse to proceed for four days, during which time the spleen became materially enlarged, he again received an intravenous injection, only one-half the dose previously employed being given, again followed by a sharp reaction with chill, hyperpyrexia, and rapid fall.

It is of special interest, too, to note that in one case of unresolved pneumonia treated by sensitised pneumobacterins comprising Groups 1 and 2, the mucus and several strains of heterogenous type, a prompt change in the blood picture took place, the leucocytes rising, with a polynuclear increase from sero-four to ninety per cent., manifested clinically

by a very prompt impress on the consolidated lung, which quickly underwent resolution. Our results also with lobar pneumonia in its active phases have been equally good, but in the acute phase there is often a tremendous increase in the total leucocyte count.

In another paper, which I hope to publish in the near future in collaboration with my associate, Doctor Beckley, we present several infections treated intravenously by serobacterins, with a full exposition both of the clinical and laboratory manifestations.

We now turn to the other phase of the proposition previously stated—that is, the value of bacterin therapy in local and chronic diseases of infectious origin. More unanimity of opinion exists in dealing with this class of cases than prevails with respect to the acute general infections. Wright argued that in the class of conditions now under consideration, time was given for limitation and circumscription of the morbid process. In consequence we do not beget an active immunity, but rather the more strict limitation of the focus and prevention of new foci. He said that we merely attempted to mimic Nature's protective measures. He cited as an instance the local and systemic disturbance which results when a tuberculous joint is too actively manipulated, or when a case of focal tuberculosis is allowed to exercise too much, fever, malaise, sweats, and prostration may result from an excessive antituberculinisation. This he termed a negative phase, based upon the opsonic index. So, too, when a focal, purulent infection is massaged, a negative phase may result. A knowledge of these facts, properly utilised, however, may be turned to therapeutic advantage, as when we strictly limit the amount of effort made in a tuberculous case, being guided by the subjective phenomena and the pulse rate and temperature. So, too, in the employment of bacterins in focal and chronic infections, such as furunculosis, acne, sycosis, impetigo, pyorrhœa alveolaris when emetine fails, or in conjunction with emetine and antiseptic mouth washes, in otitis media, sinus disease, gonorrhœal arthritis, prostatitis, epididymitis, mastoid disease due to common pus organisms or pneumococci, and in infections due to colon bacilli.

For the general practising physician stock cultures have been prepared from many strains. Auto-genous bacterins are available only when well equipped laboratories and trained assistants are at hand. The dose also has been determined by the conjoint observations of clinicians and laboratory workers, and the stock product is supplied in proper proportions. The question concerning the greater validity of serobacterins enters also into the treatment of focal infections, but is of less importance than in acute general infections, as the time element is a minor factor. As to whether their intravenous employment will yield more uniform and more satisfactory results I am at this time not qualified to express an opinion.

PRESIDENTIAL ADDRESS TO THE IRISH MEDICAL ASSOCIATION,

June 21st, 1916.

By R. MARLAY BLAKE, M.R.C.P.I.,
J.P., PRESIDENT.

GENTLEMEN of the Irish Medical Association, allow me first of all to thank you for the high honour you have done me by raising me to your Presidential Chair for the coming year. It is indeed a great and signal honour to be so selected. An obscure country doctor, you call on me to attempt to fill the chair that Dublin surgeons and

physicians of, I might say, European reputation, have so worthily filled in the past. The honour is great, the responsibility is yet greater, and though you have always, as I believe, looked upon me as a hardy, fearless fighter, who never shirked, be the odds never so great, I would remind you that men of my type do not always nor often make diplomatic or discreet leaders. Let us hope that the responsibility cast upon me may develop the qualities necessary for the post. Your President must guide debate; while not interfering with freedom of speech or taking sides in controversy, he should keep a gentle but effectual check on the more ardent spirits—the Ruperts of debate—he should know well your rules and by-laws and the precedents that regulate your proceedings. I have served a long apprenticeship now as a member of Council for many years and as your Deputy-Chairman for the last couple of years. This should help me, and with your loyal co-operation and the assistance of our wise friend Mr. Gick, I may do passably well. Certainly I shall try hard. I have model Presidents in my eye. I have sat under them and have in my time had my ardour gently but firmly suppressed by them. All I ask is that you “be to my faults a little blind, and to my failings something kind,” and I have little doubt we shall do something to strengthen, to advance our Association, an object so dear to me and to all of us.

THE REORGANISATION OF THE ASSOCIATION.

During the past year we have reorganised, and, as I trust, improved our Association. We have made few drastic changes but many minor ones that, I believe, will render our rules more flexible and more adapted to meet those recent additions to legislation that have affected and, as time goes on, will increasingly affect the Irish medical profession. In recent years three separate attempts were made in this direction. General meetings such as this appointed strong committees of earnest, sensible men. Much valuable time and anxious consideration was given to all debateable points. It is clearly impossible to please everyone. We have had keen critics, and, of course, as usual, the very men who sat most closely on the ditch were the keenest critics of the hurlers in the field. What the cost was in loss of time, fees, patients and sundry expenses to the members of those committees, some of whom came from distant parts of Ireland at great inconvenience—what that cost was it is difficult to estimate. I am sure our best thanks are due and will be rendered by you to those altruistic men.

THE PROFESSION AND THE WAR.

Gentlemen, in common with the whole nation, we have passed through a most strenuous time, and the strain is not yet relieved. The past year has brought sorrow to the homes of many of us whose gallant sons have given their noble young lives proudly, gladly for the dear land that bore them. We sorrow with them, we share their pride in gallant achievements nobly done. It should be no small source of gratification that many members of our body have answered the call of duty—when did the Irish doctor fail in that?—and are now at home or abroad ministering to the stricken—to our glorious fighting Irish boys, sharing their dangers and their hardships. Some of us, alas! were not found worthy to die for justice and for Ireland. Personally it was a great grief, a sore blow to me to be told I was too old to serve. But those of us who were refused sent our sons, and we are yet available. Have we not seen in our own Capital City how gallant veterans knew how to die?

THE CERTIFICATION QUESTION.

The past year is one to be marked with a white stone in our annals, for it has brought to a successful conclusion our long-drawn-out contest with the Insurance Commissioners, and we are top-dog.

The cardinal principle has been definitely conceded that each doctor shall certify for his own patient. On the financial side of the dispute we showed our generosity and our common-sense by conceding and agreeing to a slight diminution in our just demand. Our Association, as I hold, deserves the thanks of the whole profession for our efforts. Our labours are not yet ended: it behoves us to keep a watchful eye on our good friends the Insurance Commissioners lest perchance they filch from us the benefits we wrung from them in open fight. As in the past, through long years, we worked for and safeguarded the interests of our Poor Law brethren, so in the future we shall watchfully and fearlessly watch over your interests not only in Insurance matters, but all those cognate affairs that affect our profession.

THE POOR LAW SERVICE.

Now, sirs, a very large proportion of our members belong to the Poor Law Medical Service, and there are many grievances affecting them yet unredressed. In the fore-front let me put the questions of inadequate pay, and above and beyond all the crying injustice that, after long years of service, we can be thrown upon the world in our old age without an assured pension. The policeman, the gauger, even the downtrodden, underpaid and much sweated national school teacher, is certain of his pension on the Civil Service scale. The poor law doctor alone is left to the contemptuous pity of his masters. The Act says *may* when it should say *must* give. 'Tis but the difference of a word, gentlemen, but how pregnant with meaning and possibilities. Picture to yourself the old doctor, wearied and worn out with hardship, his sight failing, his hearing defective, his feeble limbs scarce able to bear him on his daily rounds. He knows—no one better—that he is out of date, growing daily more and more inefficient; he has lost hope, lost nerve, he dare not face any of the greater emergencies that midwifery so frequently springs upon us when two lives and the welfare of a large family depend on our knowledge of what to do, and our skill and daring to meet the emergency alone, unaided, in a country cabin on the mountain-side miles from help. The poor inevitably suffer but they are merciful and not unmindful of past services. What can the poor man do? He dare not retire; he may be offered as his sole reward the hospitality of the Poor House. This is no fancy sketch, it is living actuality. I personally have witnessed it and vouch for the truth of every word. *Hodie mihi, cras tibi*. Take the most recent instance of the sort. A doctor well known to ail of us, Dr. Kelly, of Ennis-corthy, after 38 years' service retired. He was voted just £100 a year. Thinking he was entitled to more, he appealed to the Local Government Board. His Guardians were thunderstruck at his audacity, he actually doubted their sense of justice and generosity, he had not licked their boots, and to prove his case for him—if proof were needed—they promptly cut down his pension by one-half. Now, one would have thought his chance of being favourably dealt with was an odds-on chance. Thirty-eight years' service, the ability to meet fearlessly great epidemics of fever on more than one occasion, great personal popularity, a blameless life, of the same religious belief as his masters, the misguided man even went so far as to be described as a "tried and trusty patriot of the

real Wexford brand." If that was his fate, what will be that of you and of me? *Ex uno disce omnes*. A very large number of boards of guardians were sensible enough to see in recent years that "good masters begot good servants," and gave us graded scales. The board under which I have the good fortune to serve was one of the first, and I don't think they have lost by it. In this connection I cannot altogether acquit of blame the doctors themselves. I think it was Emerson who said that every country had the laws it deserved to have. *Mutatis mutandis*. I say the doctors have in most instances the guardians they deserve to have. When we see miserable appointments eagerly competed for, all sorts of assistance called in, political, clerical, and even the power of the purse to the extent of two and three years' prospective salary by University graduates and others, what wonder pay does not improve. It is a question of supply and demand, and is governed by general economic laws. I hardly blame the guardians for *sweating* these men.

I am well assured, gentlemen, that once this awful war is over, one of the first questions that will be dealt with is Reform of the Poor Law. The English who, with that overbearing cock-sureness that renders them, in spite of their great qualities, so unpopular, and who always know other people's business better than they themselves do, in the forties of the last century foisted the inhuman degrading Poor Law system on an unwilling Ireland. Saturated as it was with the economic ideas of Cobden and the doctrinaire Manchester school, it possessed every possible fault, extravagance, harshness, inefficiency, and it bred a whole host of leather-legg'd despatch-box-bearing officials who still go about preaching economy to the poor while living on the fat of the land themselves.

It speaks well for the intelligence of the country guardians and country doctors that they gradually evolve a *modus vivendi* out of this crude mass of corruption and ineptitude. All will shortly be thrown into the melting-pot. Without trenching on the forbidden topic, politics, it is at least permissible in me to say that we are about to witness, and are witnessing, the rebirth of a nation. Are we not told that this is the day of the apotheosis of small nationalities? Let us be wise and watchful, let us strengthen our Association, let us add to our numbers. Come and join us, you who hitherto merely criticised. We want your brains, we want your help, we want a little, a very little, of your money. Union is strength. Come and join us, help on the good cause, and then, like the prolific man in Scripture, we can talk to our enemy in the gates.

I thank you for your patient hearing.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

UREA AS AN ANTISEPTIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The recent discussion of the "discovery" of the antiseptic properties of urea furnishes yet another illustration of the waste of available therapeutic skill and practical adaptation of the same, which inevitably results from the absence of anything like a central reservoir of collective professional knowledge—with carefully scrutinised contributory streams, and re-

ligiously guarded channels of distribution after due filtration through media of absolute reliability. It also represents another example of the general rule that most, if not all, of the neglected "popular" or despised "superstitious" remedies, have, when duly investigated, been found to be quite unwittingly based on a solid groundwork of scientific fact. Thus the native peasantry of the land of Linnæus testified their faith in the sanative powers of *Gaultheria procumbens*, during many generations before the birth of that monarch of botanical science, by the application of a phrase-name which, in English presentation, reads: "Stand up and walk." It also displays an instance of what will, I believe, prove to be one of the established facts of the ultimate clinical record of therapeutics, that: the medicinal agents whose claims have most successfully stood the resistless tests of time and skilled experience are those which owed their discovery to accident, and their application to empirical enterprise.

When a curiously observant boy in my native county of Roscommon, I often watched with special enjoyment the reaper's display of characteristically spasmodic energy in utilising the occasionally favourable spells of fickle harvest weather by the slashingly vigorous use of his reaping-hook. This was not—necessarily—always regulated with all the desirable engineering skill, as a badly hacked left-hand finger often revealed. And under the existing pressure of strenuous conditions, time was so precious as to overshadow the trivial claim of a small *quantum* of flesh and blood. Accordingly, the sufferer swiftly stood up and, turning his back on his fellow-workers, proceeded to micturate on the bleeding surface. When asked the reason, the reply was: "It is the best thing to prevent festering." And the origin of the popular practice would appear to be lost in the shades of antiquity. It has almost surely a genetic relationship with the panaceal claim made for cow's urine: the peasant's "all-flower water"—which contained the essence of all the curative items of the vegetable products of the earth's surface. A widely prevalent item of popular faith in "the good old times" was that a benevolent Providence had actually furnished the specific means of cure, of all the ills to which human flesh is heir, in the tissues and juices of the vegetable products of the respective areas of their endemicity. The idea had been advocated even before the days of Theophrastus and the elder Pliny. It was highly favoured by Miguel Serveto, the discoverer of the pulmonary circulation. And it has been resurrected, in a peculiarly unhealthy form, too—by the latter-day "discoverer" of the specific value of *salicin* in the treatment of rheumatic affections. For, on "looking around" for a characteristic local product of the damp soils on which rheumatism notoriously flourished, that therapeutic seer alighted with telepathic clairvoyance on the mother plant of that organic compound. I may observe, parenthetically, that the "sally-switch" treatment of rheumatism was recommended by Dioscorides, the court physician of Antony and Cleopatra; and was favourably regarded by his encyclopædic Roman commentator, Matthiolus, the "Father of Modern Therapeutics."

The modern tendency—in its characteristic environment of hurry and scurry, and aggressive advertisement, and get-practice-anyway, and "get-rich-quick" (honestly, of course, *if you can*)—has been to save time and space, as well as mentality, while humouring the sense of gustation; by the segregation of the "active principle," the presentation of readable "Directions for Use," and pro-

vision of the delectable convenience of transport in minimum of space. I have no doubt that the watery solution of urea will continue to retain its preferential position, but time has laid bare to the observant the facts that neither quinine nor methyl salicylate competently represent the collective curative powers of their respective natural media. But the old therapeutic superstitions will be found, as ever, to die very hard, if at all. They will surely linger along the by-paths of the tottering march of humanity. I well remember a Roscommon peasant, who had a large and healthy family, every one of whom he always dosed for any and every ailment with copious internal drenches of "all-flower water." And he was by no means one of the lower stratum. He was an educated man—as country education was rated—and of intelligence well above the average. But, as can well be anticipated, he preserved high-handed, as well as high-falutin', ideas of patriarchal government in the household, and never failed to act up to them. It will be readily—as well as truly—guessed that there was little malingering in that family! Then in that great Oriental reservoir of religious conceptions, ceremonies and ordinances, which has from time immemorial been furnished by India, the greatest gift of Providence to the members of the lower castes was the cow. Her milk was the manna sent from heaven, and formed the terrestrial representative of the celestial nectar. And sprinkling with her urine constituted their baptismal purification ceremony, down through all the historic ages; and tens of centuries before. So that the re-discovery of urea, and the rare antiseptic and hygienic value thereof, can cause no surprise to the initiated. I may just mention in conclusion that, after its epoch-making synthesis, urea was a good deal recommended by some enterprising practitioners as a *diuretic*!

I am, sir, etc.,

JOHN KNOTT.

Dublin. [June 20th, 1916.

DENTISTRY AND MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dentists must be gratified with your full recognition of the fact that dentistry is a legally established branch of the medical profession. The R.C.S., Eng., got power to set up a dental diploma in the Medical Bill of 1858, but it was not till 1878 that the Dentists Act made it obligatory for dentists to have a qualification. The Act soon brought into dentistry a steady supply of practitioners. The education was admirably planned, and no one unless devoid of any handicraftship could fail to come out of the final examination an accomplished dentist. The penal clauses of the Dentists Act were, like those of the Medical Act, soon found inoperative, and the object of the Act to protect the public was entirely done away with. It seems too absurd for credence that the Parliamentary draughtsmen could set up clauses which would be passed by Parliament, and would be entirely useless for the purpose owing to their obscurity and ambiguity. An unqualified man may not style himself dentist, surgeon-dentist, or dental-surgeon, but he can stick up a sign inscribed dentistry or dental surgery, and put such phrases in his advertisements as may lead even educated people to take him for a highly qualified man. This has been lately stated in your pages. The unqualified man is in most cases professionally uneducated; he is a rough mechanic who knows how to take a rough model of a mouth and make artificial teeth. Some of these men are no doubt

unconscious of the mischief they bring about through their ignorance, but there are many advertising quack dentists who are merely out for plunder. The game of these men is to supply artificial teeth very often at exorbitant prices. They entirely neglect the surgical condition of the mouth. When numbers of decayed teeth and broken down stumps are present the first imperative duty is to bring the whole thing into a healthy condition before putting in artificial teeth. This work in dental surgery is laborious and very badly paid. The quack never touches it. He fixes in a denture clasped to remaining teeth which are soon destroyed through this. Beneath the plate there mostly lie broken down stumps in the sockets. These are all in various stages of disease and keep up constant suppuration. This foul matter constantly flows into the mouth and thence into the stomach. Dr. Hunter was the first man to call attention to this source of septic infection and to demonstrate that it was the sole cause of several varieties of systemic disease, many of them progressive and fatal. There are an enormous number of such cases about owing to the increase in the number of quack dentists.

I have already taken up too much space or I might narrate a series of pitiable typical cases which I have encountered in hospital practise—all women.

I am, yours truly,
HOSPITAL DENTIST.

June 21st.

A URINARY TEST OF SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In last week's issue of your valuable journal there appears an article by Dr. C. D. Gray on a new test for syphilis by examination of the urine.

Re No. 1 solution, one is advised to dissolve 1 gm. of iodine in chloroform, but no mention is made of the quantity of chloroform to be used. At a loss, therefore, to know the percentage recommended, I used a 1 per cent. iodine solution, but in every case I have so far only got negative results, even in marked cases of syphilis—as the tendency is to yield too many positives. I feel sure that the fault lies in the strength of the iodine solution. If you could find out the exact strength needed I shall be grateful, as if the test is found reliable we have in our hands a most wonderfully simple and quick method of diagnosis.

I am, Sir, yours truly,
H. C. SAMUEL.

9 Welbeck Street, London.
June 26th, 1916.

[As the author of the paper referred to by our correspondent is resident in the United States, we have written him to favour us with the necessary information.—ED. M.P. and C.]

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

MEETING HELD ON WEDNESDAY, JUNE 14TH.

The President, MR. PRIESTLEY SMITH, F.R.C.S.,
in the Chair.

MR. G. H. POOLEY sent the further notes of a case of "Mikulicz's disease" previously shown. A growth had been removed from the left orbit with some difficulty. Vision in that eye steadily

improved for some time, but recently there were signs of return of the disease on the same side, though the scar was free from invasion. The removed material showed the appearance of small round-celled sarcoma.

Dr. F. R. YELLAND showed a patient with loss of visual orientation, following a wound received four months previously. Soon after being put to bed he had a genuine epileptic seizure, and was inaccessible for 14 hours. He afterwards had right hemiplegia, which cleared up later, but he had erroneous visual projection. The condition was now improving.

Mr. LESLIE PATON, discussing the foregoing case, drew attention to the similar case under the care of Captain Smith and Colonel Gordon Holmes, reported in the *British Medical Journal* of March, 1916. He gave the results of the tests he had carried out in the present patient. He satisfied himself that the faulty projection was not due to defective eye movements. He believed that there had been complete destruction of the right occipital cortex, the left sensory visual cortex having escaped fairly well. There seemed to have been a complete severance of the superior longitudinal commissural fibres.

Captain CARRUTHERS exhibited a case of "retinitis pigmentosa" of unusual character in a young man who had been a soldier three months. There was no consanguinity, but a younger brother and an older sister suffered from night-blindness, and as this patient could not see to drive when dusk came on, he declared sick, and so came under observation.

The case was discussed by Mr. W. LANG, Mr. STEPHEN MAYOU, Mr. J. B. LAWFOED, the PRESIDENT, and Mr. LESLIE PATON.

Captain A. C. HUDSON exhibited, in a tentative form, a giant perimeter, and invited suggestions as to improvement.

Lieut.-Colonel R. H. ELLIOT gave his experiences with a giant perimeter which he had made, and suggested possible improvements.

Dr. A. S. COBBLEDICK read a paper on

FOUR CASES OF PITUITARY TUMOUR.

The cases were all in women, three over 60 years of age. The first case showed a contraction of the visual field of 10 to 20 deg., and a scotoma for colour upwards and outwards from the central fixation point. The colour scotoma bothered her a great deal when reading, and people's faces appeared bluish. There was particular contraction in the temporal half of the field. Later she had Cheyne-Stokes breathing, very violent headache, and became drowsy. The pupils, however, were equal in reaction, and there was no papillitis; the urine was normal. *Post mortem*: a pituitary tumour the size of a walnut was found, and Dr. Buzzard regarded it as a cyst. There seemed to have been sufficient normal gland substance left to ensure normal metabolism during the six years that the symptoms lasted. The second case had right homonymous hemianopia and myxœdema. The memory had become bad, and the speech slurred and indistinct. The family and previous personal histories were good. She had well-marked myxœdema, and there was a lesion of the left optic tract, probably due to pituitary growth. Thyroid extract was given, and there was improvement in the memory and in some numbness which had been present. The appearance of the discs and the constitution of the urine were normal. There was little material change in the patient's condition for three years, but after that there was fairly rapid deterioration of vision, and the nervous

condition increased; there was also vertigo, and flickerings in front of the eyes. Her feet and hands also became larger. Later the symptoms somewhat resembled those of Menière's disease, but there was no deafness nor sickness. Case 3 had optic atrophy, obesity, myxœdema and diabetes. During four years her sight had been gradually changing, and during the last year she had become very sleepy and drowsy. There was no tendency to hemianopia in this case. Her feet and hands were now definitely larger than twelve months ago, and the memory worse. Skiagrams showed an enlarged and lobulated sella Turcica. Operation was declined. He suggested that possibly the diabetes was due to implication of the posterior lobe of the pituitary; or it might be caused by pressure on the medulla. The fourth case was aged 50, and her condition the author diagnosed as early optic atrophy, myxœdema and pituitary tumour. She had defective memory, thinning of the hair, suffocating feelings in the throat, heart attacks, and twelve months ago she was so ill that her life was despaired of. Her discs appeared normal, but the vision for white was contracted in every direction. Skiagrams showed distinct enlargement of the pituitary body, especially at the posterior part. He regarded this as a suitable case for operation.

The paper was discussed by the PRESIDENT, Mr. LESLIE PATON, Mr. STEPHEN MAYOU, Mr. WALTER JESSOP, and Mr. ARNOLD LAWSON, and the author replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD MAY 19TH, 1916.

The President, GIBBON FITZGIBBON, M.D., F.R.C.P.I., in the Chair.

ROTUNDA REPORTS.

SIR WILLIAM SMYLY read the Rotunda reports.

Sir A. HORNE said he wished to congratulate the Governors of the Hospital in granting Dr. Jellett a further extension of leave to serve his country abroad. He noted in the present report that special attention was drawn to the excellent results accomplished in the treatment of eclampsia. He did not think the disease here was milder than elsewhere, but was of opinion that one got cycles of mild and serious cases into hospital. It was important that ante-natal clinics should be attached to all maternity hospitals, so that the toxæmias of pregnancy could be recognised early. He regretted there was no mention of the subject of scopolamine-morphine treatment which occupied so much attention at the present moment in the lay press. He would also like to point out that 30 years ago a former assistant Master of the Rotunda, Dr. Bagot, was the first to perform an abdominal section for the treatment of concealed accidental hæmorrhage.

Dr. BETHIEL SOLOMONS said that he had modified his views concerning scopolamine-morphine anæsthesia since the publication of Dr. Freeland's paper on the subject in 1909. He thought that "twilight sleep" was unsatisfactory unless the method was carried out by trained assistants and nurses. He noted that two of the patients in the contracted pelvis table were not measured internally. He was aware that the authorities at the Rotunda favoured mensuration by the Skutsch instrument, and he thought it would be a good thing if there was a separate table devoted to Skutsch pelvimetry, as this would draw more atten-

tion to its use. Munro Kerr, in his textbook, and also many well-known authorities in England and elsewhere, still insisted that manual measurement of the pelvis was the best. He noted that pituitary extract was given in some cases of accidental hæmorrhage. He wished to know the size of the os when the drug was administered. He inquired the meaning of three cases of hysterotomy in the nyomectomy table—whether the hysterotomy was performed for diagnosis according to Deaver's idea?

Dr. PUREFOY said he was not an enthusiast for scopolamine-morphine anæsthesia. Amongst the patients who had died of sepsis he recollected that one had not been able to lie down for three weeks prior to admission because of great distress from hydramnios; the labour was slow, pains not ensuing for some days after rupture of the membranes. Her aspect from her admission was that of a woman dying of pernicious anæmia. He was a firm believer in the Skutsch pelvimeter, and regretted that some still relied on the digital method. He thought there was no need for intern pelvimetry in some very obvious cases.

Dr. ROWLETTE said he thought that in the treatment of puerperal sepsis, both vaccines and sera should be employed. The vaccines should be auto-genous, but pending their preparation stoek vaccines should be used. The use of these agents did not preclude any other method of treatment which might be considered advisable in a particular case. They were not to be regarded as a cure-all.

Sir WILLIAM SMYLY, in reply, said there had been so many changes in the personnel of the hospital staff during the year that it would be impossible to assign the degree of indebtedness to each member who had helped in compiling it, but Dr. Simpson had done most of the work in preparing the statistics. He was glad that Sir Andrew Horne had called attention to the Master's patriotism in going to France at considerable financial sacrifice, and also to the fact that Dr. Bagot was the first operator who had performed hysterectomy in the treatment of concealed accidental hæmorrhage. Regarding scopolamine-morphine, he had given directions that one dose at least should be given to every patient who was in the first stage of labour, but not that it should be pushed to the degree described as "Twilight Sleep."

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JUNE 23RD, 1916.

MR. CHARLES J. HEATH, F.R.C.S., in the Chair.

MOTION REGARDING WITTENBERG CAMP. EXHIBITION OF CASES.

IN introducing his motion regarding the Wittenberg Camp, the CHAIRMAN said:—

Gentlemen, you must all be aware of the terrible outbreak of typhus fever at the Wittenberg Camp for British prisoners of war in Germany. You are also doubtless aware that the circumstances under which it took place were investigated by a Committee presided over by Mr. Justice Younger. The report of that Committee is based mainly upon the evidence of Major Priestley, Captain Vidal, and Captain Lauder, of our Royal Army Medical Corps. These three are the only survivors of the six English surgeons who were sent by the Germans to the camp at Wittenberg, to take up duties which were abandoned by the German surgeons in charge. Such an abandonment of duty by medical men is both astonishing and infamous, and was made no

better when they sent British surgeons to do work which was so dangerous that they were afraid to do it themselves. Such conduct surely implied a lack of courage. There was also a lack of humanity. For while keeping out of danger by staying away from the camp, the German surgeons did not even ensure to it a proper supply of medical equipment, drugs, etc., or of food suitable for the sick. Further, they did not provide adequate clothing for the sick, coal for the fires, or even water for washing. The British surgeons' request for the separation of the sick from the healthy was refused. Dr. Aschenbach, when standing *outside* the wire entanglement which surrounded the camp, was asked by two British surgeons for "some medical requisites urgently needed." The only answer he gave was to call them "English swine." I will now quote from the report of the Younger Commission:—

"On one occasion only during the whole course of the epidemic did Dr. Aschenbach enter the hospital or even the camp. His visit took place about four weeks after Major Priestley's arrival and after some kind of order had been evolved. He came attired in a complete suit of protective clothing, including a mask and rubber gloves. His inspection was brief and rapid. For his services in combating the epidemic Dr. Aschenbach, the Committee understand, has been awarded the Iron Cross."

This inhuman conduct was rewarded! The man came once only during the epidemic, and then came covered with protective clothing. He provided no protective clothing for the British surgeons whom he thrust into the camp to attend the sick. I feel compelled to express astonishment that the medical men of neutral countries have not raised their voices and collectively protested against the conduct of Dr. Aschenbach and his subordinates, for such conduct leaves a stain upon the humane reputation of the medical profession. With these preliminary remarks I beg to move that:

"Notwithstanding the evidence contained in the report of the Bryce Commission regarding the brutality of the combatant branch of the German Army, the Fellows of the British Oto-Laryngological Society did not think it possible that members of the medical profession could have acted as Oberstabsarzt Dr. Aschenbach and other German surgeons did in abandoning the British prisoners of war at Wittenberg Camp during an epidemic of typhus fever. They are not a little surprised that medical opinion on this behaviour has not yet made itself heard in this and in neutral countries."

Dr. FREDERICK SPICER seconded the motion, and said he would have done so with greater satisfaction if it had been more strongly worded, for, after all, the instance referred to in the motion was merely a sample of what occurred daily in the war area. Still, even in its present form, the motion serves to express the sentiment of horror felt by every member of the medical profession in this country, and their thanks were due to Mr. Charles Heath for having brought the matter forward. It is time something was done to remove a disgraceful anomaly—that is, the perpetuation on the Roll of Honour of our medical societies of the names of representatives of a country which perpetrated and tolerated such vile and brutal acts. He thought the various learned societies of the country, not only the medical, but those of chemistry, law and others, should also take action and officially express the detestation which is felt and expressed all over the country at the crimes committed by Germany. There was no room for sentiment in the face of such brutal acts. To do less than he had suggested was almost as bad as toleration of brute force.

Dr. CHARLES W. CHAPMAN desired, as a visitor, to strongly endorse the resolution; he thought members of the profession could not speak too plainly on the matter.

Mr. G. W. DAWSON also supported the resolution, and in doing so said he could not understand the German doctors not attending patients suffering from typhus fever. Dr. Aschenbach need not have been so nervous about his own health, as very few healthy people contracted it. The German doctors seemed to be ignorant as to the degree of contagiousness of typhus fever.

Dr. COUBRO POTTER desired also to associate himself with the resolution. He was certainly of opinion that now was the time to act. At another medical meeting recently, when a similar resolution was discussed, some of the speakers said the time had not yet arrived when any such resolution should be passed, that the proper time for that was after the war. That seemed to him a great mistake, for if the war should last a considerable time, were such acts to continue to be tolerated? If neutral countries were to see the record of the passing of this resolution, they might feel induced to do something on the same lines. Though mildly worded and less strong than some of the Fellows might have wished, it was in the right direction.

Dr. PENNY also supported the resolution, and agreed that if it had been made more severe it could not have been out of place. It was in the nature of a protest, and he agreed in making a signal protest against the whole German nation.

Dr. LOOSELY associated himself, as a visitor, with the resolution. The sooner the action of Germans towards our countrymen who were prisoners in their hands was called combined attention to, the better for the prisoners still there. He was ready to give all the support he could to such a scheme.

Dr. G. F. LONGBOOTHAM (Middlesbrough) supported the motion, and asked whether any steps of a similar nature had been taken by other societies.

Dr. C. K. MOSELEY (Ipswich) expressed his cordial sympathy with the motion. He did not know why the resolution expressed surprise that medical opinion in neutral countries had not made itself felt concerning this behaviour in Germany. He thought an inclusion should be made of the medical opinion in this country, which had not proved as strong as it might be. In fact, except at a recent medical meeting, at which it was vetoed, there had been scarcely any medical expression of detestation. It would be impossible to make the wording of this resolution too strong.

The CHAIRMAN, in reply, said that if the press censor in Germany allowed the truth to come out, medical black sheep, such as those at Wittenberg, might be condemned by the Germans themselves. This resolution, if passed, might lead to others. He thought, particularly, that the medical profession in the United States should have protested. The other neutral countries were relatively so weak that they could be brow-beaten.

The resolution was carried unanimously.

DISCUSSION ON CASES, ETC.

Dr. FREDERICK SPICER'S cases: (1) A case of bradycardia, or slow action of the heart, in a boy, æt 15. He showed the patient because of the danger of operation in such conditions. On arranging for a nasal operation, it was stated that there was something wrong with the heart, for which he had been under the care of Dr. Charles Chapman years before. He communicated with Dr. Chapman, whose reply was, that bradycardia existed and rendered an operation dangerous. Dr. Chapman treated the boy for six months, and then saw Dr. Loosely, the anæsthetist, before anæsthetic was

given. The operation was carried out at a nursing home, every precaution having been taken to be ready for any emergency which might arise. The turbinals were removed, and there was not much bleeding. Suddenly, at the end of the operation, the heart and breathing stopped, and he thought the patient was dead. Artificial respiration, however, revived him. This was such a remarkable fulfilment of Dr. Chapman's fears, that he went round to see him in order to learn more about it, as he did not want to run such risks if they could be avoided.

Dr. CHARLES W. CHAPMAN (who attended the meeting as Dr. Spicer's guest) said his habitual attitude was not alarmist. He did not think every case of heart trouble contra-indicated operation. There were some, however, in which operation was more than ordinarily risky, and this he regarded as one of them. He saw the patient when five years of age at the Hospital for Diseases of the Heart. He had been cyanotic since birth. He gave many other details of the case, which was considered to be one of congenital heart disease. He described the case at length, also the means of settling the question of heart block by the inequality of the pulsations of the ventricle and auricle.

The case was discussed by Dr. COUBRO POTTER and by Dr. LOOSELY, who gave the anæsthetic at the operation, and was on his guard at the time, having been warned of the risks. He said that after the recovery from the attack at the operation there were some slighter attacks.

Dr. MOSELEY also discussed the case.

II. Dr. SPICER brought forward this case to illustrate what he regarded as the best method of removing malignant growth from the naso-pharynx, *viz.*, to perform a preliminary laryngotomy, split the soft palate and hold the portions apart.

Mr. CHARLES HEATH showed I. a case of catarrhal deafness. On one side the hearing had been improved by treatment, on the other by disease. One ear had been painted with a solution of cantharidine after his method with good results, the other had been the seat of acute otitis media, perforation and discharge for five days. The improvement in hearing resulting from the abscess was remarkable.

This case was discussed by Dr. SPICER, Dr. PENNY, Dr. MOSELEY and Dr. COUBRO POTTER.

Mr. HEATH, in reply, pointed out that if paracusis were well marked the hearing of the majority of these cases could be improved. They practically all had indications of obstructive deafness. He was not yet satisfied with his method of treatment because it did not relieve every case, but he was satisfied that it was far more effective than any other which had yet been devised. Some of the cases he had treated five years ago still had excellent hearing.

II. A case in which follicular tonsillitis occurred when the Eustachian tube became patent after a mastoid operation by the exhibitor's conservative method. Mr. Heath explained the mechanism by which the throat was involved. He pointed out that the syndrome was fairly common, *viz.*, conservative mastoid operation, clearing of the Eustachian tube, and follicular tonsillitis. He had seen four cases of it in the last month.

Dr. FREDERICK SPICER thought Mr. Heath's explanation was a likely one; he had not seen it mentioned elsewhere.

III. A case of patching up a deaf ear which had been irreparably damaged by suppuration of over 30 years' duration. Though cure was impossible the life was made safe and the hearing good by the conservative mastoid operation.

IV. A case of aural suppuration of 13 years' dura-

tion in which the frequent occurrence of pain led to the performance of the conservative mastoid operation.

This patient, a Lieutenant in the R.A.M.C., had undergone treatment for years without effect. Since the operation, which took place four weeks before the meeting, the perforation had healed and the hearing considerably improved.

V. A case of aural suppuration lasting forty years, in which vertigo recently developed. The vertigo was cured and the hearing restored by the conservative mastoid operation. Patient's age was 66.

SPECIAL REPORTS.

LOCAL GOVERNMENT BOARD REPORTS ON CEREBRO-SPINAL FEVER (a).

THE Local Government Board has issued a valuable and comprehensive series of "Reports on Cerebro-spinal Fever." Dr. A. Eastwood reports on the bacteriological aspects of the carrier problem; Dr. F. Griffith, on identification of the meningococcus in the naso-pharynx; Dr. W. M. Scott, on meningococci occurring in the spinal fluid and the naso-pharynx; Dr. R. J. Reece, on the epidemic prevalence of the disease in England and Wales in the first six months of 1915; and Dr. Bruce Low on the prevalence and distribution during recent years.

It will be seen that all these subjects are of prime importance to the bacteriologist or the sanitarian, and each author has treated his subject fully and with careful references to previous work. We can only refer here to a few points of interest. Dr. Eastwood, basing his opinion on a careful study of the morphological, cultural and serological reactions of the meningococcus as obtained from various sources, comes to the practical conclusion that all naso-pharyngeal strains which answer to the recognised culture tests are to be regarded as capable of producing cerebro-spinal fever. An identical conclusion is come to, chiefly on serological grounds, by Dr. Griffith. Dr. Scott investigated a number of cases of the disease, and compared the organisms separated from the spinal canal with those separated from the naso-pharynx. He found that the maximum period during which meningococci may be isolated from the naso-pharynx of convalescents exceeds three months. The meningococci isolated from the naso-pharynx in seven cases of the disease were identical with those isolated from the spinal fluid of the same patients. Micro-organisms indistinguishable from meningococci by microscopical and cultural methods were found in 22 per cent. of 138 persons, non-contacts, from an urban population. No opinion is expressed on the point, but the facts we have quoted support the view that meningococcal infection is a fairly widespread condition of which meningitis is only a rare accompaniment.

THE MENTALLY DEFECTIVE.

At the conference on sanitary administration under war conditions, held on June 10th, at the Royal Sanitary Institute, a discussion took place on the Mental Deficiency Act.

Dr. A. B. Ritchie (Medical Officer, Manchester Education Committee) spoke of the great need for schools for backward children with supervision before the issue of certificates. There was no

(a) "Reports to the Local Government Board on Public Health and Medical Subjects." New Series, No. 110. London: H.M. Stationery Office. 1916. Price 2s.

advantage in keeping defective children at ordinary education after the age of 14; the next two years should be given to industrial training.

Mr. Leslie Scott, K.C., M.P., who presided, said that special schools should educate children capable of becoming self-supporting citizens. The lower-grade cases should be cared for by the Poor Law authorities, and should have training with a view to permanent supervision and assistance. A result of the war was suspension of loans for institutions, though need for them was great; there was a dearth of doctors; and local authorities were hampered by depletion of staffs. For these reasons the working of the Act was difficult, but everything possible towards carrying out its intention should be done. Educational authorities would find scope for useful work in ascertaining the number of mentally defective children within their districts, and the lists should differentiate those that were educable from those that were not. The work-house was not an ideal institution for the purpose, but with certain conditions use could be made of it during the war.

The Rev. J. Darmody (Wolverhampton) urged that local authorities should never send a case to an institution without full knowledge and frequent inspection. He maintained that there were many institutions utterly unfit for the treatment of the mentally defective.

The Chairman asked that the names of such institutions should be given to him in confidence.

ANOTHER MEDICAL V.C.

IN a supplement to the "London Gazette" issued on June 21st, it is announced that the King has been pleased to award the Victoria Cross to Captain John Alexander Sinton, M.B., I.M.S., for most conspicuous bravery and devotion to duty. Although shot through both arms and through the side, he refused to go to hospital, and remained, as long as daylight lasted, attending to his duties under very heavy fire. In three previous actions Captain Sinton displayed the utmost bravery.

THE EGYPTIAN CAMPAIGN.

IN despatches received from General Sir John Maxwell and Major-General Sir A. Wilson, dealing with the military operations in Egypt from November, 1914, to March, 1916, reference is made to the work of the 137th Field Ambulance:—

Major R. M. Knox, I.M.S., and his officers were energetic and expeditious in the disposal of the large number of wounded on their hands.

The names of the following medical officers are mentioned:—

STAFF, ETC.

Lieut.-Col. H. Burton, C.I.E., I.M.S., Major J. D. Graham, I.M.S., Capt. S. W. Jones, I.M.S., Lieut.-Col. (temp. Col.) W. H. B. Robinson, C.B., I.M.S., Lieut.-Col. Sir D. Semple, Dir.-General of Dept. of Public Health, Dr. J. Creswell, i/c Govt. Hosp., Suez; Dr. W. C. Hayward, i/c Govt. Hosp., Port Said; Major G. W. Heron, R.A.M.C., Health Off., Suez Canal Area; Dr. L. Cambolin, Med. Off. Suez Canal Co., Ismailia; Lieut.-Col. E. P. Sewell, R.A.M.C., A.D.M.S.; Surg.-Major and Hon. Surg. Lieut.-Col. R. Bullock, T.D.; Surg.-Gen. R. W. Ford, C.B., D.S.O., D.M.S.; Col. T. B. Beach, A.M.S.; Surg.-Major B. Pares, D.S.O.; Major H. V. Bagshawe, R.A.M.C., A.D.M.S.; Lieut.-Col. Sir J. Rogers, K.C.M.G., D.S.O., A.M.S.; Maj. C. S. Spong, D.S.O.; Local Major W. Hastings; Local Major E. V. Oulton; Local Major A. F. MacCallan; Local Major W. Hayward; Local Major C. Ekins; Local Major

L. P. Phillips; H. V. Keatinge, C.M.G.; J. E. Cresswell; Armand Ruffer, C.M.G.; A. Granville.

MEDICAL SERVICES, A.M.S., AND R.A.M.C.

Lieut.-Col. W. G. Pridmore, C.M.G., I.M.S., No. 5 Ind. Genl. Hosp.; Lieut.-Col. J. B. Smith, I.M.S., Bombay Pres. Genl. Hosp.; Lieut.-Col. P. J. Lumsden, I.M.S., No. 8 Ind. Genl. Hosp., Cairo; Major T. B. Kelly, I.M.S., 105th Ind. Fd. Amb.; Major W. R. Battye, D.S.O., I.M.S., 108th Ind. Fd., Amb.; Maj. W. D. Ritchie, I.M.S.; Capt. R. H. Bharucha, I.M.S.; Major J. N. Walker, I.M.S., 108th Ind. Fd. Amb.; Capt. C. H. Fielding, I.M.S., 89th Punjabis; Col. C. W. R. Healey; Col. F. W. G. G. Hall; Temp. Col. F. D. Bird; Lieut. Col. O. L. Robinson; Lieut.-Col. H. E. R. James, C.B.; Major J. M. Darling; Major A. N. Fraser; Major C. P. Thomson; Temp. Major C. C. Choyce; Temp. Major W. T. Prout, C.M.G.; Capt. R. E. Todd; Capt. H. W. Carson; Capt. E. C. Lambkin; Capt. W. W. Treves; Capt. C. Robb; Capt. S. W. M. Jones (Spec. Res.); Capt. E. J. Bradley (Spec. Res.); Temp. Capt. G. Blacker; Temp. Capt. S. A. Boyd; Temp. Lieut. J. G. Willmore; Lieut.-Col. A. H. Lister, 1st Scot. Genl. Hosp.; Capt. E. W. H. Groves, 2nd Southern Genl. Hosp.; Capt. D. G. Kennard; Capt. C. Carr, 1st Scot. Genl. Hosp.; Capt. W. R. Douglas, E. Lancs. Div. Fd. Amb.; Lieut. (temp. Capt.) G. R. Rickett; Lieut.-Col. (temp. Col.) C. Stonham, C.M.G. (deceased); Lt.-Col. (temp. Col.) A. H. Tubby; Major (temp. Col.) A. W. Mayo Robson, C.V.O.; Capt. (temp. Col.) V. W. Low; Capt. (temp. Col.) Sir V. A. H. Horsley; Lieut.-Col. A. R. Tweedie; Lieut.-Col. T. H. Forrest; Major C. P. Thomson; Capt. W. A. Brechin; Capt. G. E. J. A. Robinson; Major (temp. Lieut.-Col.) F. H. Francis.

AUSTRALIAN AND NEW ZEALAND FORCES.

Major and Hon. Lieut.-Col. J. G. Tedder, Australian A.M.C.; Col. (Hon. Surg.-Gen.) W. D. C. Williams, C.B.; Lieut.-Col. G. T. Hall, N.Z.A.M.C.; Temp. Lieut. J. W. O'Brien, 1st Aust. Div. Train.

CANADIAN A.M.C.

Lieut.-Col. F. Hetherington, C.M.G.; Lieut.-Col. H. R. Duff (deceased); Capt. G. E. Kidd.

THE CAMPAIGN IN GERMAN EAST AFRICA.

In a despatch received from Lieut.-General Smuts, Commander-in-Chief of the East African Force, dated April 30th, 1916, and dealing with the British campaign in East Africa, the following reference is made:—

"Exceptionally heavy work has been thrown upon medical officers and *personnel*. All wounded have been treated and evacuated expeditiously, and the number of sick who passed daily through the hands of the medical authorities, more especially since the cessation of active operations, has been very great. Great credit is due to Surg.-General G. D. Hunter, C.M.G., D.S.O., and his assistants.

MEDICAL REWARDS FOR GALLANTRY.

D.S.O.

HIS MAJESTY THE KING has been graciously pleased to approve of the appointment of the undermentioned officers to be Companions of the Distinguished Service Order, in recognition of their gallantry and devotion to duty in the field. The specific acts for which the rewards have been granted will be announced as soon as possible in the *London Gazette*:—

Temp. Capt. Walter Dawson, M.B., R.A.M.C.
Capt. William Archibald Miller, M.B., R.A.M.C.,
Spec. Res. (attd. 22nd Royal Fusiliers).

MILITARY CROSS.

His Majesty the King has been graciously pleased to confer the Military Cross on the undermentioned Officers and Warrant Officers, in recognition of their gallantry and devotion to duty in the field:—

Temp. Capt. Frederick Chas. Atkinson-Fleming, M.B., R.A.M.C. (attd. 5th Royal Inniskilling Fusiliers, for conspicuous gallantry and devotion to duty when tending casualties during and subsequent to a hostile attack. He worked without ceasing under difficult and dangerous conditions.

Temp. Lieut. Francis Keene Marriott, R.A.M.C. (attd. Headquarters, 182nd Field Artillery Brigade), for conspicuous gallantry and devotion to duty when he went out to tend the wounded of two batteries which were under heavy shell fire.

The following have also been awarded the Military Cross. The specific acts for which the awards have been granted will be announced as soon as possible in the *London Gazette*:—

Temp. Capt. Cyril Mary Brophy, R.A.M.C. (attd. 18th London Rifles, T.F.).

Capt. John Arthur Cullum, Canadian A.M.C. (attd. 28th Infantry).

Temp. Capt. John Mcir MacKenzie, M.B., R.A.M.C., (attd. 6th Northumberland Fusiliers, T.F.).

Capt. William Hunter Riddell, M.B., Indian Medical Service.

Temp. Lieut. Charles Cyril Okell, No. 6 Field Amb., R.A.M.C.

LITERARY NOTES.

FROM Messrs. John Wright and Sons, Ltd., Bristol, comes the 15th edition of Mrs. J. Langton Hewer's "Our Baby for Mothers and Nurses." (1s. 6d. net stiff boards; 2s. 6d. net limp leather.) No words of ours are necessary to commend a book which has met with such decided success. The advice given is sound and practical, and we have pleasure in calling attention to this new edition, which has evidently been very thoroughly revised.

* * *

MR. JAMES BERRY, F.R.C.S., Senior Surgeon to the Royal Free Hospital, who, with his wife, Dr. Frances Berry, proceeded to Serbia last year in medical charge of the Red Cross Mission to that unhappy country, has a book in the press entitled "The Story of a Red Cross Unit in Serbia," which deals with the recent history and the aims of the Serbs, as well as with the exciting travelling and other experiences of the mission, the establishing of hospitals, sanitation, and the treatment of a severe epidemic of typhus. It tells of the Austrian invasion and shows how the unit fell into the hands of the enemy. The volume is illustrated by photographs taken by various members of the party, and will be published by Messrs. J. and A. Churchill.

* * *

We have received a copy of "An Every Day Directory for War Time," issued by the Women's Imperial Health Association and Women's Emergency Corps. It contains information regarding the numerous bodies and institutions engaged in work connected with the war. For example, it gives the names and addresses of those ladies who forward clothes and comforts to British Prisoners of War in Germany, and gives the address of the Belgian Labour Exchange which finds employment for Belgians and supplies workers as desired. The booklet, which is published at 6d., should prove very useful.

* * *

We have received a copy of an admirable pamphlet compiled by the Association of Infant Welfare and Maternity Centres, entitled "To Wives and Mothers," and published by the National League for Physical Education and Improvement, price 3d. The advice is well

chosen and simply expressed, while stress is appropriately laid upon the most important subjects. A short and practical account of the hygiene of pregnancy, with a list of the preparations necessary for confinement, is followed by detailed instructions for breast feeding and bottle feeding and the general management of the infant. We are glad to see an entire page devoted to the condemnation of baby "comforters." After some useful hints on the management of older children, a few of their common ailments are dealt with in detail—diarrhoea, measles, whooping cough, etc. Some simple cookery recipes are introduced, and the last few pages are occupied with general instructions as to cleanliness and ventilation. The most striking points about this pamphlet are the entire absence of any confusing or complicated directions, and the continued appeal to common sense whereby hygienic living is presented as an attractive and attainable mode of life.

* * *

THE *British Journal of Surgery* (John Wright and Sons, Bristol) continues to maintain the high level of surgical journalism with which it started. A considerable portion of the later issues, as is only to be expected, has been devoted to some of the graver surgical problems of the European war. In the current issue (Vol. III., No. 12), such questions as the prognosis and treatment of gunshot injuries of the femur, cranium, and thorax receive prolonged consideration. Major Hey Groves, who has been a pioneer worker in the modern treatment of fractures, opens with an illuminating account of the difficulties to be met with in treating severe gunshot fractures of the femur. From an extensive experience, he lays down the cardinal precept: Early immobilisation, which shall not interfere with dressings; such immobilisation is best carried out by a wire cradle splint on the principle of the double-inclined plane; extension should be applied once the flesh wounds are in a healthy condition, and it is best carried out by means of a transfexion pin, as the wounds of the soft parts do not readily lend themselves to the older methods of using adhesive plaster for the purpose. In his experience, good results are obtained in 74 per cent. of cases, a satisfactory percentage, when one considers the amount of sepsis and comminution caused by modern missiles. Surgeon-General Sir A. Bowlby puts the primary mortality at the clearing station as high as 14 per cent., initial shock and collapse, hæmorrhage, gas gangrene, and the presence of other injuries caused by shell fire all constituting very grave factors in the prognosis. Primary amputation was necessary in 6 per cent. or 7 per cent. of cases, being usually called for at the casualty station on account of severe laceration of main vessels, comminution of condyles with involvement of the knee joint, or extensive destruction of soft parts. In the presence of grave sepsis, or gas gangrene, the traditional methods of amputation have not, in many cases, given the expected results; in such cases the "flapless" method of Fitzmaurice Kelly would appear to be of distinct value. "*Autres temps autres mœurs*"—and surgeons who are unable to see for themselves conditions as they actually are behind the battle line should not be too hasty in their criticisms of newer and, perhaps, revolutionary methods of treatment for these ghastly wounds of limbs, thorax, or cranium, devised by the men actually on the spot. For men serving in base hospitals at home, we can imagine no more instructive reading than this journal. One of the most attractive features of earlier issues was the graphic account by some "Eye-witness," luckier than his fellows, of visits to famous clinics abroad. Might it be possible that some contributor could give us a peep at the actual work of some of the famous surgeons of our Allies, and their methods of treatment of similar problems to those under discussion?

WILLESDEN Council marriage-rate last year was the highest and the birth-rate the lowest for more than 40 years. The birth-rate is now only 22 per 1,000 of the population, compared with 44 in 1875.

SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specialy compiled for THE MEDICAL PRESS AND CIRCULAR.

Treatment of Acute Yellow Atrophy of the Liver.—Longridge (*R.A.M.C. Jnl.*, June, 1916) records the case of a soldier who reported sick in Gallipoli on October 1st, and was admitted to the Giza Hospital, Egypt, on October 10th, 1915. The patient complained of feeling sick, had some pains in his legs and loss of appetite. There was slight jaundice, the bowels were acting normally, his temperature was 99.6° F., and his pulse normal. Three days later the patient was deeply jaundiced, the stools were clay-coloured, and the urine mahogany colour. The patient then became very ill, with severe epigastric pain with occasional fainting attacks, and some vomiting. Examination of the urine showed that it contained besides bile considerable quantities of leucin and tyrosin, the patient's temperature being subnormal and his pulse seventy. On October 15th the patient was delirious, vomiting bilious fluid, and he was passing some blood by the bowel. Some diminution in the liver dulness was noted. Injections of glucose solution were given to the patient per rectum, and one hundred cubic centimetres of a two per cent. solution of sodium bicarbonate solution were injected hypodermically night and morning. The patient was considered to be suffering from acute yellow atrophy of the liver, and Colonel William Hunter, who saw the patient, agreed with the diagnosis. On October 18th the patient was much better, was passing considerable quantities of urine, which still contained leucin and tyrosin, but no albumin or sugar. The patient made a slow but uninterrupted recovery, the liver dulness again becoming normal. Longridge states "the atrophy is an acute autolytic degeneration of the liver, a process which is much more rapid in an acid than in an alkaline medium, and therefore demands a free administration of alkali to bring about its arrest. It is closely akin to what occurs in certain cases of eclampsia, in which, I believe, I was the first to point out a marked diminution of the alkalinity of the blood (estimated by Wright's method). In these cases of eclampsia I have learned to regard as an ominous symptom complaint of pain in the epigastrium, such as this patient had." K.

Nephritis without Albuminuria.—Parkinson (*Brit. Jnl. of Children's Diseases*, May, 1916) records the case of a boy, aged three and one half years, who was admitted to hospital suffering from acute pneumonia. A fortnight later the boy's chest was normal and he appeared quite well. During his illness his urine did not show anything abnormal. Just fourteen days after admission to hospital slight œdema appeared on the boy's face, and on the following day there was general anasarca of the body and limbs. The child became very ill and stupid, and a blood pressure of 90 mm. was recorded. No trace of albumin was ever found in the urine, though on microscopic examination granular and hyaline casts with a few red blood corpuscles were found. The boy made a good recovery, and was discharged from hospital in perfect health. Parkinson believes that the "child had an attack of acute nephritis, following but not due to pneumonia, causing œdema and the presence of casts and blood cells in the urine, but without albuminuria." The condition seems to be more common in scarlatinal nephritis than in nephritis from other causes, and in one case, seen by Dr. J. D. Rolleston, the existence of the acute nephritis was verified by *post-mortem* examination. K.

Inoculation of Man with Mixed Vaccines containing Bacillus Typhosus, B. Paratyphosus A, and B. Paratyphosus B. Coppinger and Gibson (*R.A.M.C.*

Jnl., May, 1916) record some experiments made with vaccines containing these organisms with the view of determining the reaction produced and the antibody formation. From these experiments they draw the following conclusions:—(1) That the highest dosage used is the best for producing lasting antibodies against these three organisms, and that the vaccine should be given in two doses rather than one, both on account of the reaction produced by the single dose of one cubic centimetre, and also on account of the higher antibody content produced when the two doses are given. (2) The want of antibody production for bacillus paratyphosus A is a very strong feature of these experiments when compared with those elaborated for bacillus typhosus and bacillus paratyphosus B. As to the immunity produced against this organism, that can only be decided by actual trial, but the results obtained in the course of these experiments seem to point to the fact that the bacillus paratyphosus A content of the vaccine may not achieve its object to the same extent as that of bacillus typhosus and bacillus paratyphosus B." K.

Trench Foot.—Waller and Rideal (*R.A.M.C. Jnl.*, May, 1916) in a report of investigations on the condition known as "trench foot" make the following suggestion for treatment. A salted ointment, such as salted lard, should be used for protecting the foot against water. The salt would further act as an antiseptic. A liberal amount of ointment is necessary, as much as one hundred grammes for each leg, with five or ten per cent. salt. The writers point out "that officers' spiral puttees contract five to six per cent. of their length when they are soaked in water." K.

Delivery by the Natural Passages after Cæsarean Section.—Williams (*Amer. Jnl. Obs.*, lxxiii., 3) asks, in the absence of disproportion between the foetus and pelvis, may a patient, after Cæsarean section, safely be allowed to go into labour and be delivered by the natural passage? To answer this, experiments were made to determine the strength of scars in animals. The reported cases of rupture were analysed and subsequent histories of patients were investigated. Analysis of the reported cases of rupture showed thinning of the scar in practically every case, some due to infection, others to lack of care in suturing. The following conclusions are drawn:—A carefully sutured and well united scar will withstand any strain that can be endured by uterine muscle. Rupture is always secondary to unusual weakness of the scar dependent on imperfect consolidation, most frequently due to failure to include the whole thickness of the muscle in the sutures or having them too far apart; infection in certain cases. Therefore it seems evident that given a uterus which has been sutured with care, and where there has been no sepsis during convalescence, labour may be gone through without risk when there is no disproportion in foetus and pelvis. F.

The Indications for Cæsarean Section.—Boyd (*Amer. Jnl. Obs.*, lxxiii., 4) says that the procedure is now more and more frequently resorted to for relative indications, and even in some cases for the child's life alone. In pelvic deformity in a large group of cases it is impossible to determine the right treatment prior to the onset of labour, as a disproportion often disappears after a careful test, and unless this test is made many needless sections will be performed. Avoidance of infection is the chief need in making the test of labour,

for it is infection rather than the length of labour, even after rupture of the membranes, which makes the case a bad surgical risk. As long as the aetiology of eclampsia is obscure its treatment by section is questionable, and in the majority of cases manual dilatation with forceps or version will be the better treatment. Placenta prævia is considered a very questionable if ever justifiable indication, and many sections appear to the author to be indefensible. Those now advocating Caesarean section for placenta prævia, eclampsia, etc., must bear the culpability for the deaths which may result from uterine rupture at a later time. F.

Morphine and Scopolamine in Gynæcological Operations.—Morrison (*Amer. Jnl. Obs.*, lxxiii., 3) reports his finding in fifty cases in which injections of morphine and scopolamine were given to a degree of complete narcosis. Injections of respectively 1-6th and 1-100th to 1-50th of a grain were given and repeated in half an hour, repetition being continued until the narcosis was complete. If the respiration was slowed and the pupil contracted without complete narcosis, scopolamine was continued, while if there was restlessness and the face was red scopolamine was discontinued and morphia given. After two injections, if narcosis was not complete at the end of half an hour, but there was evidence of the action of scopolamine, an injection of apomorphine, 1-10th to 1-20th of a grain was given. This often produced an apparent effort by the patient to vomit, and then complete narcosis set in. Narcosis took from one to two and a half hours to complete, and then lasted after the operation for five to nine hours. It appears to be very deep. Respiration is slowed to about twelve per minute, and there is complete relaxation. There is risk of the tongue falling back. The after effects are satisfactory, and the patients appear to be comfortable and well. F.

The Cause of Carcinoma.—Rockey (*Surg., Gyn. and Obs.*, xxii., 2) says that it is only where long-continued or repeated irritation destroys the basement membrane and unduly stimulates a defensive karyokinesis, that the adjacent mesoblastic and epiblastic cells lose their antagonism for each other and mingle, that the invasion of the mesoblastic tissues by immature epiblastic cells takes place, and a cancer is formed. The theory is drawn from the fact that certain cancers develop from evident chronic irritations, which may be of great variety—thermic, traumatic, radiant, or chemical. The only common condition present in all cancers is a defensive reaction on the part of the cells, first manifest in the production of new cells. F.

Wassermann Reaction in Obstetrics.—Commiskey (*Amer. Jnl. Obs.*, lxxiii., 4) examined 1822 women and 1074 infants. Eight per cent. of the mothers gave positive results, and eleven mothers who gave negative reactions had children who gave either positive or doubtful reactions. Eighty-two per cent. of the women with positive reactions had no history or evidence of disease. The previous history of the positive cases showed that 33 per cent. of the multiparæ had previous abortions, miscarriages, or still births, but this is only 3 per cent. higher than an equal number of negative women. The number of cases followed up afterwards was few, but in these there was found to be some variation in the findings from the original findings. The findings in infants would appear to be irregular, but generally negative, irrespective of the findings in the mother, and might remain so for years. The death-rate amongst children in the first ten days of life was found to be four times as great in those of Wassermann positive mothers than when the mother and child were negative. F.

Captain (temporary Major) J. Innes, M.B., Highland Casualty Clearing Station, has relinquished his commission on account of ill-health. Major Innes is a well-known Aberdeen doctor.

OBITUARY.

DEPUTY SURGEON-GENERAL EDWARD MALCOLM SINCLAIR, LONDON.

DEPUTY SURGEON-GENERAL EDWARD MALCOLM SINCLAIR died in London on June 14th, aged 84 years. A son of Dr. Martin Sinclair, of Edinburgh, he qualified M.R.C.S. Eng. and M.D. St. Andrews in 1853, and entered the Army Medical Service the following year. In the Crimean war he was at the siege and fall of Sebastopol, receiving the medal with clasp and the Turkish medal. He also served through the Indian Mutiny, taking part in several actions, and being present at the siege and capture of Lucknow. In the Transvaal campaign of 1881 he was Principal Medical Officer on the lines of communications and the base, and for his valuable services he was mentioned in despatches. General Sinclair retired in 1888.

DR. J. H. DAVIS, M.B., Ch.B., LIVERPOOL.

DR. J. H. DAVIS, of Liverpool, who was severely injured in a collision with a tramcar in St. Mary's Road, Garston, died on June 21st at Garston Hospital, as a result of his injuries. Dr. Davis, who was fifty-one years of age, was educated at Queen's College, Belfast, and qualified M.B., B.Ch., B.A.O., R.U.I., in 1899. He was a well-known practitioner in Liverpool, and was a lieutenant in the R.A.M.C. and senior medical officer at Reading Military Hospital.

DR. GEORGE BARNES, L.R.C.P., M.R.C.S., L.S.A., BRIDGWATER.

THE death has occurred of Dr. George Barnes, at the age of 81 years. Educated at Charing Cross Hospital, he qualified M.R.C.S. Eng. in 1856, L.S.A. in 1858, and L.R.C.P. Edin. in 1860. He was formerly M.O.H. for the Chard District, and physician to the N. Staffs Infirmary.

LABORATORY NOTES.

"MARTINDALE" TABLETS THYROID GLAND. (W. MARTINDALE, LONDON, W.)

THESE tablets are issued in two strengths— $1\frac{1}{2}$ gr. and 5 gr.; i.e., they are stated to contain respectively $1\frac{1}{2}$ gr. and 5 gr. of standardised thyroideum siccum. The method of standardisation, we take it, is by estimation of the iodine content. The products afford a suitable means of administration of thyroid when doses of $1\frac{1}{2}$ gr. or more are prescribed.

LYSOL BRITISH MADE.

(LYSOL, LTD., 9-10, ST. MARY-AT-HILL, E.C.)

WE have received a sample of "L" Brand Lysol manufactured by the above firm. It is stated to be equal in every respect to the German product, except that, owing to the great demand, the British Lysol has not been allowed to mature. Like the enemy-made substance, "L" Brand Lysol is miscible in chloroform, alcohol or glycerine without becoming cloudy or turbid. It contains a constant 50 per cent. of free cresols. In the manufacture, pure caustic potash is used and the correct percentage of soap is ensured. Our experience is that "L" Brand Lysol is an effective antiseptic, which can be used in all cases where in pre-war days the German product was employed.

MEDICAL NEWS IN BRIEF.

National Medical Union.

THE annual meeting of the National Medical Union was held at the offices, 346, Strand, on June 24th. It was reported that about one-third of the members were engaged on war service, and several of them had gained distinctions. Dr. V. T. Greenyer, who occupied the chair, explained a scheme prepared by him for a medical service for the genuinely necessitous classes of the community. A resolution from the Edin-

burgh Medical Guild was adopted in favour of allowing any insured person who makes personal application to make his own arrangements with any registered medical practitioner willing to attend him.

Dr. Alexander Morison presided at the dinner held at the Café Monaco. Proposing the toast of "The National Medical Union," he said their desire and hope was that the National Insurance Act should fail even more than it had already done. The Union had continued to justify its existence by assisting non-panel practitioners. Dr. Greenyer, who responded, said the Union was continuing to fight disinterestedly for the freedom and honour of the medical profession. He thought the Government had at last thoroughly found out, to their dissatisfaction, that they had been trying to carry out a function which they were not able to perform, and which they ought never to have attempted, the result being failure. The individual bargaining by the Government with the practitioner was a fraud. The Union intended to make it plain to the Government that they would have to come to the medical profession to get the work done properly. Dr. H. B. Greene observed that, while it was no use flogging a dead horse, it was important to remove the carcass, so that it could do no harm. That was what would happen to the Insurance Act. Dr. G. D. Wilson proposed "The Scottish Medical Guild," and Dr. Frederick Porter made acknowledgment.

Objections to Doctors' Capitation Grant.

STIRLINGSHIRE Insurance Committee at Stirling on June 22nd adopted a resolution expressing the opinion that the payment to medical practitioners of a capitation fee of 6d. per person for the attendance and treatment of insured persons who have been recommended by insurance committees for sanatorium benefit (domiciliary treatment) should be discontinued, and that steps should be taken to have the remuneration of medical practitioners made dependent upon the actual attendance and treatment given. Figures were submitted showing that the amount paid to doctors in the area in respect of this domiciliary 6d. was £731 in 1913, £716 in 1914, and £654 in 1915, while the sums which would have been approximately due to them for these years on the basis of a payment by fees at 2s. 6d. per visit for two visits per week per insured person were respectively £45, £66, and £42. The practitioners actually attending domiciliary cases numbered 11 in 1913, 12 in 1914, 11 in 1915, out of 80 on the panel list.

The Sale of Cocaine.

IN the House of Commons on June 22nd, Mr. Herbert Samuel, answering Colonel Norton-Griffiths, said: "The sale of cocaine to members of his Majesty's Forces has been made an offence by order of the Army Council under Regulation 40 of the Defence of the Realm Regulations. Under the Acts governing the sale of poisons cocaine can only be sold by registered chemists to persons known or introduced to them, and after entering in the poisons book the particulars required by the schedule to the Act of 1868. I am considering what further action should be taken.

Mr. Herbert Samuel, replying to a question by Sir R. Cooper about the sale of pick-me-ups containing ether and cocaine in West End shops, said that *coca liquidum*, being a preparation of coca, was covered by the recent order of the Army Council. This substance was, moreover, in Part II. of the Schedule to the Poisons and Pharmacy Act, 1908, and was therefore subject to the restrictions as to sale laid down in the Poisons and Pharmacy Acts. Ether was not a poison within the meaning of these Acts.

Motor Ambulance Gifts.

THE King inspected at Buckingham Palace on June 24th a convoy of motor ambulance cars purchased with part of the £40,000 subscribed by the members of Lloyd's and presented to the French Army, through the British Ambulance Committee.

The convoy includes 20 ambulances, two reserve ambulances, one light lorry, one travelling workshop, and one staff car, and is intended to take the place of

Ambulance Section No. 2, which has done excellent work on the French line since December, 1914. It will operate behind the lines at Verdun. The sum subscribed not only covers the cost of the two convoys, but also their maintenance for 18 months. One ambulance and the staff car are the gift of Mr. Herbert Austin, of the firm by whom the whole were built.

As the convoy entered the Palace grounds about 11 o'clock it was cheered by a large crowd which had collected, and M. Paul Cambon, the French Ambassador, who was present, acknowledged the compliment. The cars were driven past the King, who stopped and made a close inspection of the travelling repair-shop. He afterwards expressed his confidence that the convoy would prove of great service and wished all belonging to the party Godspeed.

Another convoy, purchased by the British Sportsmen's Motor Ambulance Fund was inspected on Saturday by Queen Alexandra in the grounds of Marlborough House, and was afterwards handed over to the Wounded Allies Relief Committee and to the Sir Arthur Du Cros Ambulance Convoy.

Combating Venereal Disease.

DR. MATTHEW HAY has written the Public Health Committee of the Aberdeen Town Council as follows:—"In view of the desirability of making more ample provision within the city for dealing with venereal diseases, the serious effects of which on the health of the nation, and especially of urban communities, and perhaps more particularly of seaport towns, is emphasised in the recent report of the Royal Commission, and in view also of the undertaking recently given by the Government that the Imperial Treasury is willing to bear three-fourths of the expenditure which any local authority may incur in making provision for the diagnosis and treatment of these diseases—both diagnosis and treatment requiring in many cases the use of methods that cannot be easily carried out by the ordinary medical practitioner—I beg to suggest to the committee that they recommend to the Town Council that a remit be made to the committee to prepare, for the consideration of the Council, such a scheme for dealing with venereal diseases as will meet with the approval of the Imperial authorities, and entitle the Council to receive the promised Government contribution."

Walsall Infantile Mortality.

ALDERMAN C. C. WALKER, chairman of the Health Committee, pointed out at a meeting of Walsall Town Council, on June 16th, that the annual health report showed that the rate of infantile mortality last year rose from 115 to 149 per 1,000 births. It was admittedly a serious matter, though the increase had been general throughout the country. It had been thought that as people in Walsall had been earning good wages an opposite condition of things would have existed. The only explanation of the increase which could be given was that women had been extensively employed in the factories of the town. He expressed the hope that the Council would see its way to appoint more lady health visitors.

Dr. Layton said if mothers could be educated in feeding their children useful service would be done. He agreed that one of the crying needs of the day was for decent houses for the working-class population.

The Mayor expressed a hope that the establishment of a Child Welfare Society would prove of value. Already over 100 voluntary workers had been enrolled as members.

Sheffield Infirmary Needs.

THE great need of additional income to enable the Sheffield Royal Infirmary to carry on its valuable work efficiently was emphasised by Mr. H. H. Bedford, who presided over the general quarterly Board of Governors, held on June 21st.

The Chairman said he would like to mention the great work the Royal Infirmary was doing, free of all cost to the State, for the wounded soldiers of the country. Since the annual meeting in April nearly

200 soldiers had been admitted, including many long and serious cases.

The increase in the price of almost every commodity was sending up the expenditure by leaps and bounds. Two items, meat and milk, would cost this year nearly £1,500 more than last year, while the total expenditure for the year was estimated at nearly £25,000. There were, he said, many firms who did not subscribe towards the upkeep of the institution. There surely could be no more suitable recognition than that of having one's private or trading name enrolled on the list of annual subscribers.

The Chairman also referred to the excellent services rendered by the Royal Infirmary staff, and particularly by the members of the honorary medical staff. The staff, though depleted by the military necessities, was rendering in a time of great stress yeoman service to the institution. It gave him pleasure to acknowledge the help the Royal Infirmary had received since the annual meeting from a generous donor. The gift had come at a very opportune moment, and the Board were deeply grateful.

Medicinal Herbs.

LECTURING on medicinal herbs at Caxton Hall, Westminster, Mr. E. M. Holmes, of the Pharmaceutical Society, suggested that large landowners should lay out their lands for the cultivation of herbs and plants, so as to retain in this country a trade which, before the war, was largely in the hands of Germany and America.

"Horse Pickling" in London.

THE Essex Appeal Tribunal has granted conditional exemption to a horse slaughterer, in support of whose claim it was stated that horses had now to be pole-axed, as bullets for the "humane killer" were unobtainable.

An inspector of the Royal Society for the Prevention of Cruelty to Animals said that there were more crippled horses in London now than before the war, the reason being that the best horses had been taken for the Army. At the present time, too, horses were not sent abroad as formerly; they were killed and "pickled" in London, and he had had a large number of prosecutions against people who caused lame animals to travel. The appellant did a large amount of slaughtering for the society.

The South African Hospital.

THE South African Military Hospital has just been officially handed over to the War Office.

The hospital, which is a model institution in every way, for situation, roomy buildings, and modern equipment, holds 304 beds, and its entire cost was defrayed by the South African community in this country. The completion is chiefly due to Sir Lionel Earle, Secretary to the Office of Works, who obtained the King's sanction for the site in Richmond Park, to Mr. Allison, the architect, and to the engineer, Mr. McFerran, all of whom gave their services.

Colonel Stock and a capable staff of South African nurses are in charge, and it is stated that patients will very shortly be received.

New Clinic for Disabled Soldiers.

ON July 3, at 126, Great Portland-street, W., there will be opened a "Physical Clinic" for the treatment of wounded and disabled soldiers. The object of this clinic is the treatment of stiffness following wounds and also of various types of disablement. Good results have been obtained in these conditions at the Grand Palais Hospital in Paris, notably with the *eau courante*, or whirlpool bath.

The whirlpool bath will be an important part in the treatment to be carried on at the new Physical Clinic. The bath has lately undergone a rather interesting development, and is expected to achieve important results. The excellent service it has already rendered in France makes it possible to look forward to a time when the deformities now so frequently met with in soldiers with healed wounds may be mitigated if not cured.

The British Red Cross Society are taking an active interest in the clinic. It is expected that a number of doctors will view the installation this week.

Chemical Society and Alien Enemies.

At the adjourned extraordinary general meeting of the Chemical Society, held at Burlington House, on June 21st, the following resolution was carried:—

"The Chemical Society considers that it is neither compatible nor consistent with its loyalty to the Crown, whence the Royal Charter under which it works was derived, to retain any alien enemies upon its list of Honorary and Foreign Members. It is, therefore, resolved that the names of A. von Baeyer, T. Curtius, E. Fischer, C. Graebe, P. H. R. von Groth, W. Nernst, W. Ostwald, O. Wallach, and R. Willstätter, who were elected under happier conditions in recognition of their eminent services to chemical science—for which the society still holds an undiminished appreciation and regard—be, and they are hereby, removed from the list of Honorary and Foreign Members.

Birkenhead's Ambulance.

THE "Birkenhead" ambulance, built as the outcome of the generous response to a Mayoral fund, is a handsome car, equipped to take both seated and stretcher cases, and cost about £500. It is so arranged that four lying-down cases can be carried at one time, or either or both pairs of stretcher supports can be lifted out of position, thus allowing the whole or part of the accommodation to be used by men whose injuries do not debar them from standing or sitting. Conspicuously on the slate-grey coloured sides are painted the name of the ambulance and the arms of the borough. The vehicle makes a useful addition to the already big fleet of motor ambulances available for Red Cross work in Birkenhead.

Scholarship for Liverpool University.

DR. NATHANIEL EDWARD ROBERTS, M.B., C.M., of Y Craig, Menai Bridge, Anglesey, formerly of Liverpool, medical practitioner, some time assistant medical officer of the Port of Liverpool, who died on February 19, leaving estate valued at £11,800, with net personalty £11,706, left an immediate legacy of £500 to the Chancellor of Liverpool University for the benefit of the university, and another £1,000 for the endowment of a scholarship in the department of Infectious Diseases, payable on the death of a niece.

The late Sir Joseph Fayrer and Falmouth.

At the last meeting of the Falmouth Town Council it was reported that the family of the late Sir Joseph Fayrer had presented a handsome marble bust of their father to the Town Council. It was decided to place the bust in the council chamber, one of the members remarking that no one had done more to make public the natural gifts of Falmouth than the late Sir Joseph Fayrer.

Effects of War.—Dundee Royal Lunatic Asylum.

THE annual report of Dr. Mackenzie, the Medical Superintendent, was submitted at the 96th annual meeting of the Dundee Royal Lunatic Asylum, held on June 10th.

At the date of the last annual report, the Medical Superintendent stated, 70 patients were resident in Gowrie House—28 men and 42 women. During the year 15 patients had been admitted—9 males and 6 females—and 14 patients had been discharged, 3 males and 11 females. Of these, 13 had been discharged as recovered, and 8 had died. The total number under treatment during the year was 87, and the number remaining at the present date was 63—29 men and 34 women. Alcohol was the cause of breakdown in four instances, physical shock was responsible for two cases, and three were due to hereditary causes.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations, have been granted the L.S.A. diploma of the Society, entitling them to practise medicine, surgery and midwifery:—H. Archer, H. N. Eccles, E. D. G. Murray, and M. B. M. Tweed.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

LETTERS TO THE EDITOR and Original Papers intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of bona fides. These should be addressed to the Editor at the Offices of this Journal; if in Ireland, to the Dublin Office, 29 Nassau Street; from other parts of the United Kingdom, these should be addressed to the London Office, 8 Henrietta Street, Strand.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s., post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

EXEMPTION BECAUSE OF NOSE.

EXEMPTION has been granted by the Middlesex Appeal Tribunal to a man who is an expert in a business which requires an extraordinary power of smell.

It was stated that the man had a marvellous "nose."

SPINSTERS AS HEALTH VISITORS.

ONE of the arguments used at the Islington Borough Council against the appointment of health visitors to assist in the cause of child welfare was the possibility of spinsters being appointed to instruct married women in the duties of motherhood.

IN CELLAR COOL!

THE population of Rheims now includes only 4,110 children. These children have been to day school in the cellars under shell-fire for nearly two years.

The other day a French composition was set to a class in the Joffre School, and the subject chosen by the master was "Narrative of this morning's bombardment."

WAR INSANITY.

IN his annual report to the governors of the Cumberland County Asylum, Dr. Farquharson stated that the war had had no special effect upon the incidence of insanity in that part of the country.

J. L. (Co. Mayo).—The microscope you describe is a very good one, and should be very suitable. The mechanical stage is a convenience, but not a necessity. The Thoma-Zeiss hæmocytometer is by far the most convenient and trustworthy.

"CHAIR" DAY.

For the Earl of Beaconsfield's Memorial Cottage Hospital, Wycombe had a "chair" day on June 24, a miniature specimen of the town's industry being worn.

CHILDREN AND VENEREAL DISEASE.

THE Local Government Board have asked the Metropolitan Asylums Board to undertake the control of children suffering from venereal disease. It is stated that the City guardians have offered accommodation.

DR. CHRIS. CROSS.—The gentleman referred to is not on *The Medical Register*; probably you have made a mistake in the name or initials. We suggest that you look up afresh your reference, and we will help you on hearing again.

MARGARINE FOR BUTTER.

THE Blakewell (Derbyshire) Board of Guardians have decided to substitute margarine for butter in the workhouse dietary. Several guardians stated that they had "sampled" both, and were unable to detect any difference.

DR. A. S. (Royaumont).—The book referred to is in the hands of the reviewer.

THE WIDOW'S MITE.

THE Camberwell Guardians have received the following letter from a workhouse inmate:—"Dear Gentlemen,—Will you please accept the widow's mite to help you mend the wounded soldiers that come home to you here, and tell them they are not forgotten. I have saved a penny a week for two years. I have enclosed 9s.—I am, yours obediently, J. D." The widow has been thanked and the money sent to the Red Cross Fund.

FOOD RINGS.

MR. WILLIAM LAWTON, Secretary of the Society of Medical Officers of Health, will lecture at the Prince's Skating Rink on June 28th, his subject being "Markets, Food Rings and Marketing."

Vacancies.

South Devon and East Cornwall Hospital, Plymouth.—House Physician. Salary £150 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

London Temperance Hospital, Hampstead Road, N.W.—Assistant Resident Medical Officer. Salary £120 a year, with residence, board, and laundry. Applications to the Secretary.
